Vol. XVII. New York, January, 1905. No. 1.

TYPICAL AMERICAN HYDRAULIC AND TRANSMISSION PLANT

AMERICAN RIVER ELECTRIC COMPANY'S SYSTEM.

BY C. W. WHITNEY.

The American River Electric Company has recently completed and placed in successful operation in central California a hydro-electric power and transmission system, which is typical of the best water-power plants on the Pacific Coast. The plant has nothing of the spectacular about it, unless it be that it is located on one of the most picturesque mountain streams in California; but it is characterized by a high standard of construction and well merits description. Special mention will be made further on of several unusual and noteworthy engineering features which have been worked out in the design and construction of the system.

The generating plant of the American River Electric Company is located on the South Fork of the American River about six miles from Placerville, which, in turn, is 90 miles by railroad east of Sacramento. Power is supplied over an 80-mile circuit to Stockton and over a 30-mile line to Folsom and vicinity; while lines to Sacramento and other points are projected for the near future.

The American River and Silver Creek, its principal tributary, have their heads on Pyramid Peak, Mt. Tallac and other snow-covered peaks of the Sierra Nevada Mountains in Eldorado County. The waters from Echo and several other lakes are included in the drainage basin of the American River, while the same watershed sends its waters on its eastern slope into the beautiful and much renowned Lake Tahoe. The drainage basin of the South Fork of the American River covers about 550 square miles. In the deep ravines and on the shaded slopes of the higher mountains the snow remains the year round, so that the permanence of the water is always assured. The American River flows through a section that is quite heavily timbered with pine, cedar and spruce, and extensive lumbering operations are still being carried on a few miles above Placerville. In the section where the American River Electric Company has done its hydraulic development, a portion of which is shown in Fig. 1, the river flows between banks which rise from 1,000 to 1,500 feet and are still covered with much of the virgin forest. In the 7½-mile length of the river bed between the company's dam and its power house, the river has an average fall of between 75 and 80 feet to the mile, and the canal system that has been constructed utilizes this fall to give a total static head at the power station of 575 feet. The river has a minimum recorded flow of about 100 second-feet at that point, while the maximum flow is, of course, high. When some of the accompanying pictures were taken there was a flow of about 5,000 second-feet in the river, while Fig. 6-E shows it at low-water stage.

FIG. 2.—POWER HOUSE, SHOWING PIPE LINE AND ROCK CREEK.

FIG. 1.—GENERAL VIEW OF POWER HOUSE, TRANSFORMER HOUSE AND SWITCHES, WITH TRANSMISSION LINES CROSSING RIVER.

The company's dam spans a narrow place in the river at a point about 12 miles from Placerville. The dam is of a timber-crib, rock-filled construction and abuts on bed rock at each end. It is 210 feet long, 30 feet high and has a width of 50 feet at the bottom and 19 feet at the crest. A gen-

eral view of the dam and headworks is shown in Fig. 6-C, while Fig. 6-H shows the dam and the reservoir created by it. The water is backed up in the canyon for about half a mile, the purpose of the stored water being principally to equalize the irregular flow of the river caused by evaporation, raises, etc. The headworks, Fig. 6-C, of the canal line, are located at the north end of the dam and consist of heavy wooden gates raised and lowered by handwheel screws.

The water is taken from the reservoir at a point near the surface, thus giving the flume over 20 feet elevation above the river bed at the start. The total length of canal line from the dam to the penstock above the power-house is a little over seven miles, being exactly 37,283 ft. 5 ins. The general contour of the canal is shown in Fig. 3. Wherever it was possible, ditching was resorted to, but on the upper portion of the work a wooden flume had to be depended upon and over four miles of it was built, the longest single stretch being 14,202 feet long.

Fig. 4 shows the construction of the flume, the trestle supports varying, of course, to conform to the nature of the ground covered. The framework consists of 4-in. x 6-in. x 6-ft. 6-in. posts, braced by 4-in. x 4-in. pieces to 4-in. x 8-in. x 8-ft. sills that rest on 6-in.

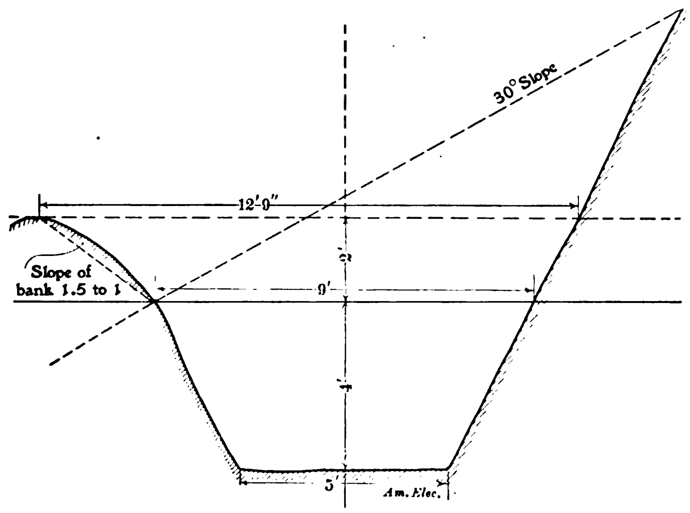

FIG. 3.—DITCH DETAIL.

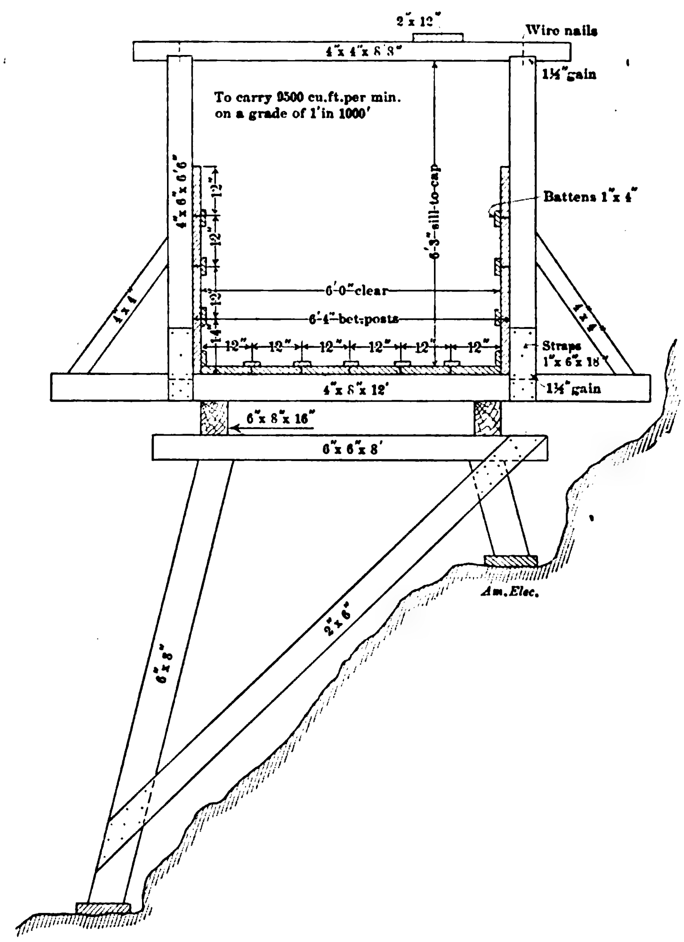

FIG. 4.—FLUME DETAIL.

sills that rest on 6-in. x 8-in. x 16-ft. stringers. The bents are placed 16 feet apart and between them are three sets of intermediate posts. The flume is planked to a height of four feet with 2-in. x 12-in. plank, giving a clear width of 6 feet. The planks are battened with ¼-in. x 4-in. strips, battens as well as the floor and side planks being surfaced so that the flow of the water is smooth and even. There is a clear height in the flume to the caps of 6 ft. 3 ins., and with the sides planked 6 feet high the flume will have a capacity of 264 second-feet of water. At present the company is using about 50 second-feet. The flume and ditch have been built with a drop of 1 foot in 1,000, so the total drop in the canal line is nearly 40 feet—sufficient to give the water a velocity of about 4.4 feet per second. Figs. 6-I and 6-M illustrate typical flume sections, Fig. 6-J is a view showing a tributary creek fall on the right, and Fig. 6-A is a scene about the middle of the canal.

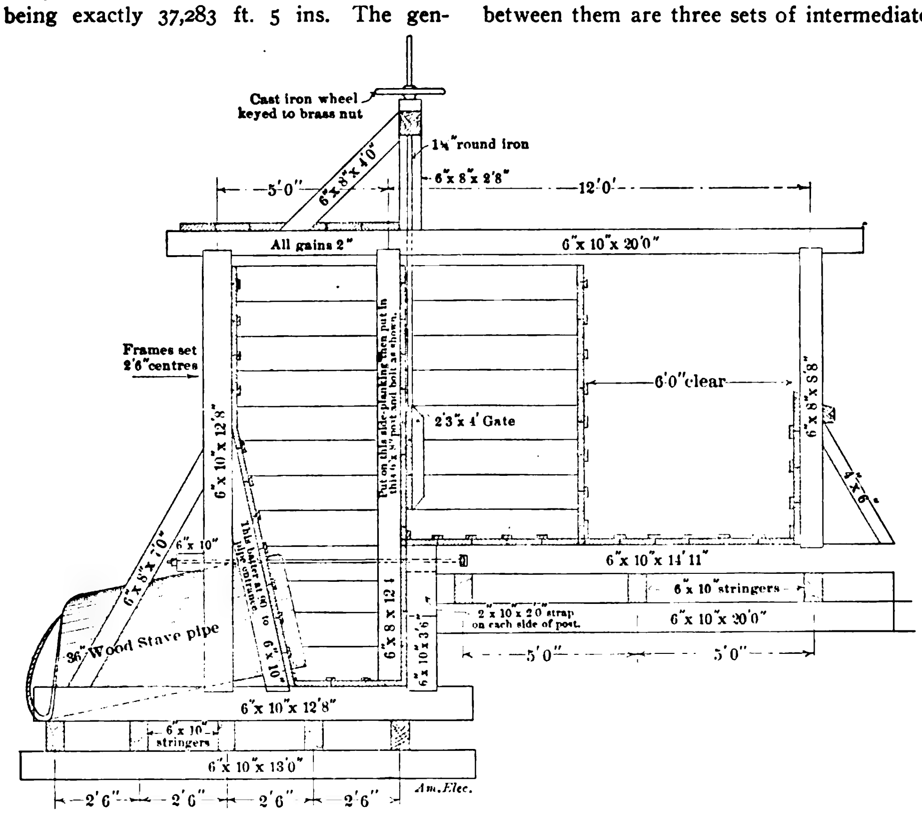

FIG. 5.—SECTIONAL VIEW OF PENSTOCK.

Ditching was used where the banks of the river are less steep and where there would be comparatively little danger or rock or land slides. The standard ditch construction is that shown in Fig. 3, the ditch having a width of 5 feet at the bottom and 12 ft. 9 ins. at the top of the lower bank which is placed 6 ft. above the bottom. On a 30-degree slope the excavation per linear foot amounted to about 60 cu. ft. In places where the lower bank was of loose soil, 1-in. boards were placed on the sides of the ditch to lessen the tendency to break. Figs. 14-A and 14-B are views taken during the construction of the ditch.

Between the dam and the penstock there are several small streams which flow into the American River from the north bank, but none of these are of material value except Mosquito and Jay Bird Creeks at the lower end. In these two creeks combined there is enough water during the winter months to run the entire plant, so branch flumes with small diverting dams have been

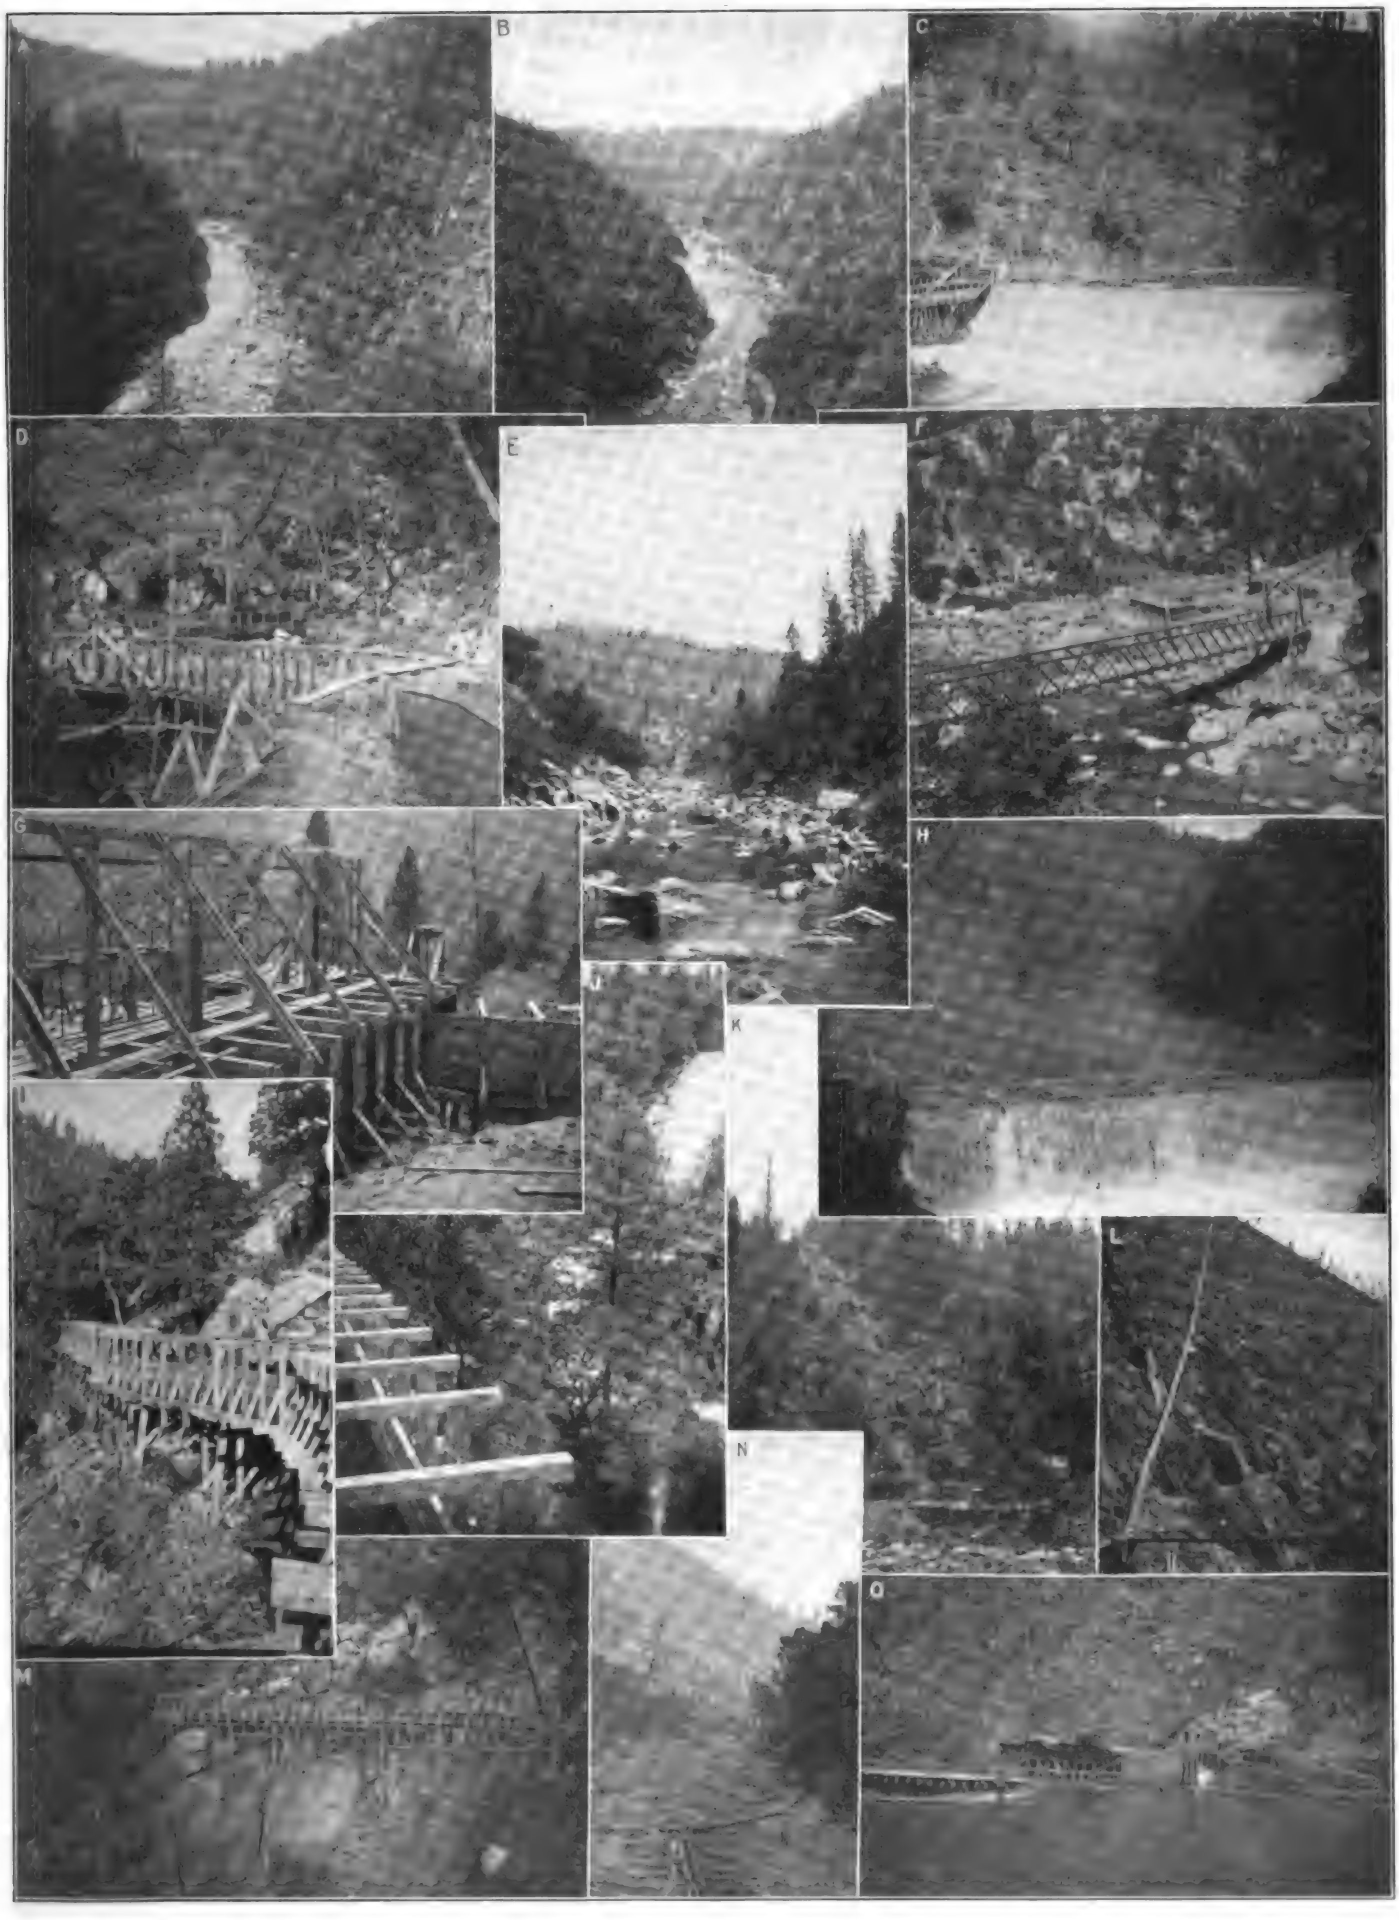

FIG. 6.—TYPICAL SCENES ALONG THE FLUME LINE OF THE AMERICAN RIVER ELECTRIC COMPANY.

built in order that these waters may be turned into the main flume if desired. These branch flumes are about 4 ft. x 4 ft. in the clear and are built with a fall of 1 foot in 10. The arrangement at Jay Bird Creek is illustrated in Fig. 6-D, a portion of the main ditch and flume being shown in the foreground. The provision of these two branch flumes makes it possible to shut down the main flume above for repairs or alterations should it become necessary. At convenient points along the main flume are waste gates for controlling the depth of the water. A 12-in. plank on top of the caps affords an easy path for the use of the flume man in patrolling the canal.

In building the flume, water was let into it and lumber floated down from the dam as the construction proceeded down stream, as there were but one or two roads in the vicinity and they would have been of but little assistance. The rough timbers were obtained from a lumbering camp higher up on the river and were delivered by means of a narrow-gauge railroad to a point about half a mile above the dam. Here a wooden chute, 2,400 ft. long and stretching from the top of the bank to the river's edge, was constructed and all the lumber used was dropped down this chute into the river. The velocity acquired by the timbers was frequently sufficient to carry them to the opposite bank of the river. Fig. 6-L is a view of the chute and gives an idea of the operation. After being delivered in the water the lumber was floated down to the dam, where a temporary saw mill was installed to a size and surface. Fig. 6-N shows a part of the lumber above the dam after the

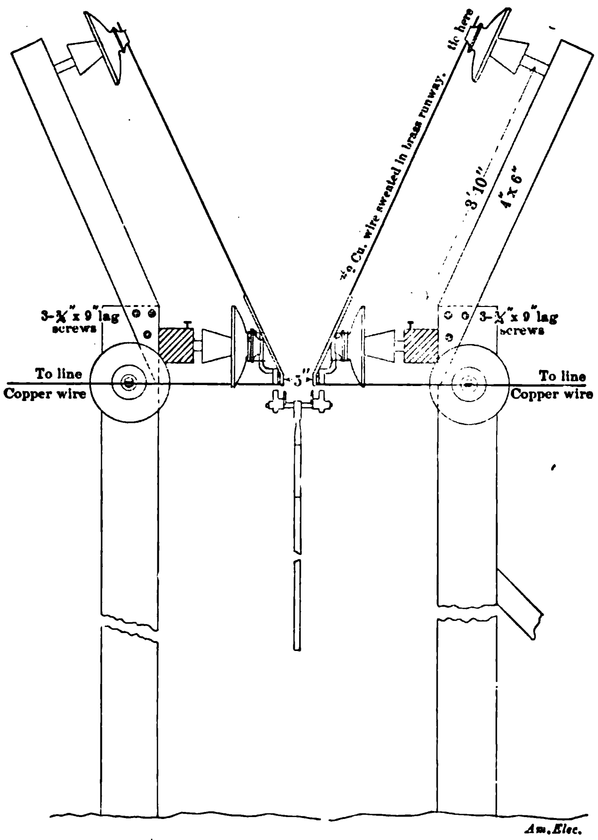

FIG. 7.—ASSEMBLY OF SWITCH.

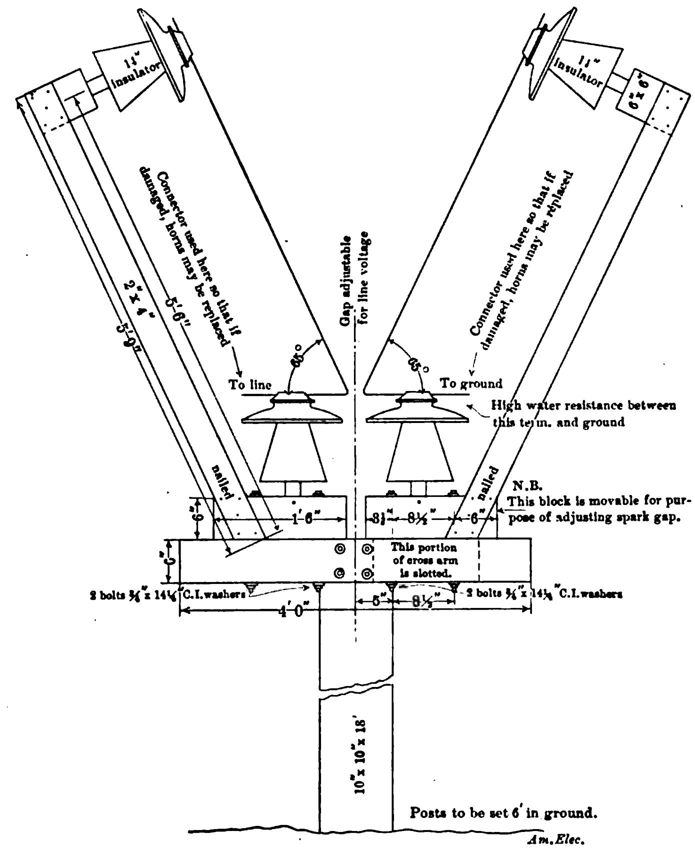

FIG. 8.—DETAILS OF LIGHTNING ARRESTER.

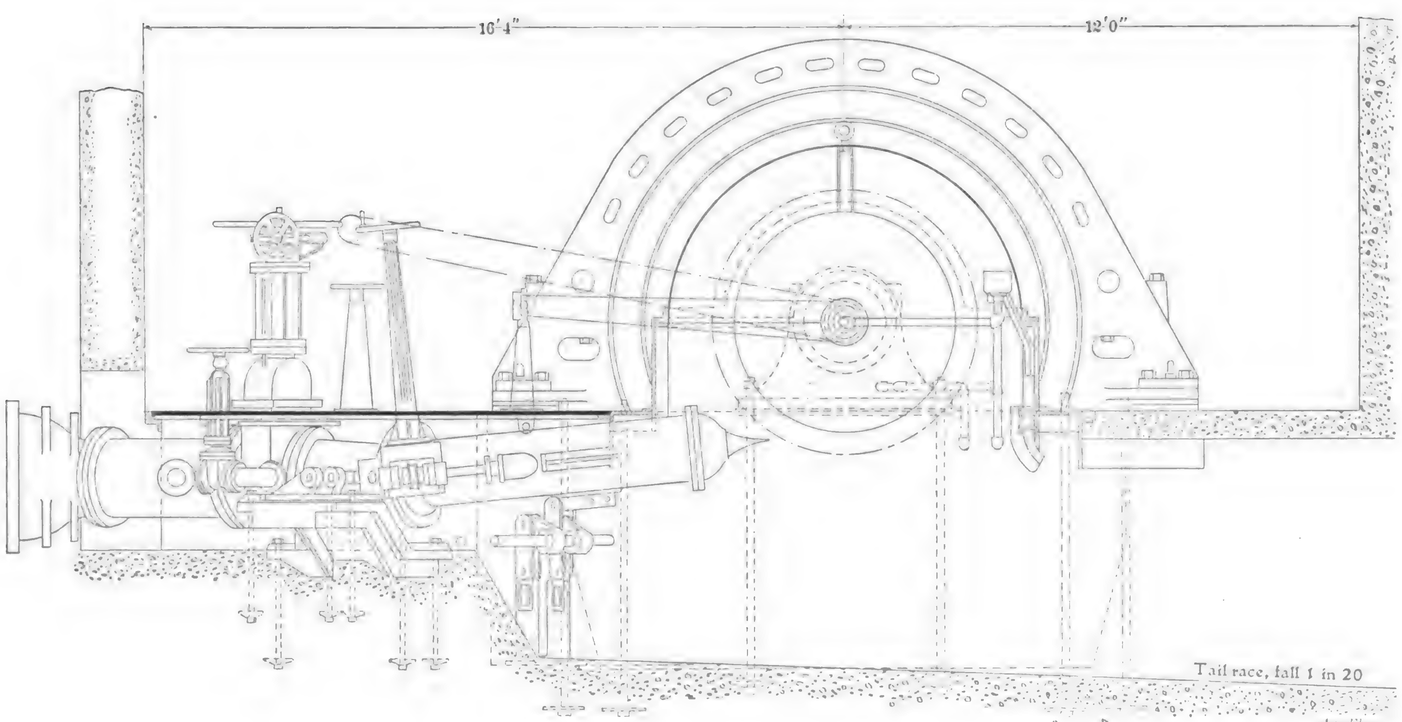

FIG. 9.—ELEVATION OF WATER-WHEEL AND GENERATOR IN POWER HOUSE.

water had been let out of the reservoir. The flume and ditch were built by the San Francisco Construction Company, of San Francisco.

The penstock, Fig. 6-G, is located on the brow of the hill overlooking the junction of Rock Creek with the American River. It is constructed of timber and is 60 feet long. The main flume, 6 feet in height, runs along one side and the water passes through wire screens and wooden gates into the pipe boxes. Each of the two pipe lines is served by three 2 ft. 3 ins. x 4 ft. gates operated by handwheels and rods from the platform above. The waste water is carried off at the end of the penstock through a branch flume to a spillway apron that discharges into Rock Creek and which is large enough to take care of all the water in case of a shutdown. Fig. 5 is a view of the penstock showing gate-gear, etc. There is room for a third pipe line and set of gates when the load on the station demands an addition. The screen is used to collect leaves, twigs and other debris and extends the whole length of the penstock. The screen is double and is made of ½-in. square mesh No. 6 galvanized iron wire. For convenience in handling for cleaning purposes, the screen is mounted on angle-iron frames 3 ft. x 7 ft. in size. The pipe boxes are each 5 ft. wide, 10 ft. long and 12 ft. deep, and the lower part of the outside wall is given a batter to set at right angles to the axis of the outgoing pipe.

From the penstock two pressure pipes 1,614 ft. long and 36 ins. in diameter lead to the power house. The upper portion of the pipe line, as shown in Fig. 14-C, passes over an easy grade so that for a distance of 400 ft. it was possible to use redwood stave pipes as the head developed in that distance was but 120 ft. At the end of the 400 ft. of redwood pipe the riveted sheet-steel pipe construction begins, the thickness increasing with the head. The first 400 ft. is of No. 10 steel and this is followed by 150 ft. of 3-16 in., 150 ft. of ¼ in., and 364 ft. of 7-16 in. pipe, making a total of 1214 ft. of steel pipe. Figs. 14-F and 14-G are views taken during the laying of the steel pipe. The pipes are securely anchored with concrete at the strain points and have air valves to relieve the air pressure in starting up after a pipe has been emptied.

A maximum static head of 575 ft. is obtained from the water level of the penstock to the centre of the nozzles. Just outside the power-house each pipe line branches into a Y, each leg leading to a water wheel.

In addition to the main pressure pipes a small amount of water is diverted from the penstock to a settling tank from which a 2½-in. pipe is carried to the power house. This water, which has a pressure of about 200 pounds, is used for the regulators of the water wheels.

An ingenious device has been installed at the penstock to indicate to the station operator the level of the water. A ball float is connected with a lever so that as it moves up and down with the changes in water level it moves an iron core in and out of a solenoid that is connected in series with an alternating-current ammeter on the switchboard in the power house. The solenoid is specially wound so that the changes in current as produced by the movements of the float can be read off accurately in inches from a special scale on the ammeter.

The power house, Figs. 1 and 2, is located above high-water line on a point of land between the junction of the American River and Rock Creeks. The latter stream sends down a considerable amount of water, which for eight months of the year would be sufficient to operate the entire power plant. The company controls the water right on Rock Creek, and with about six or seven miles of flume and ditch could bring its waters into the same penstock that is now used for the main stream. In time it may prove desirable to have this auxiliary supply. The power house is built of concrete with a steel truss roof covered with slate and is thoroughly fireproof. In this building are located the generator and exciter units and low-tension switchboard, no potentials above 2200 volts being allowed there. A separate building, as will be mentioned later, is provided for the transformers, while the high-tension switching is all done in the open air. Fig. 2 is a general view of the power station building, showing the pipe line at the right.

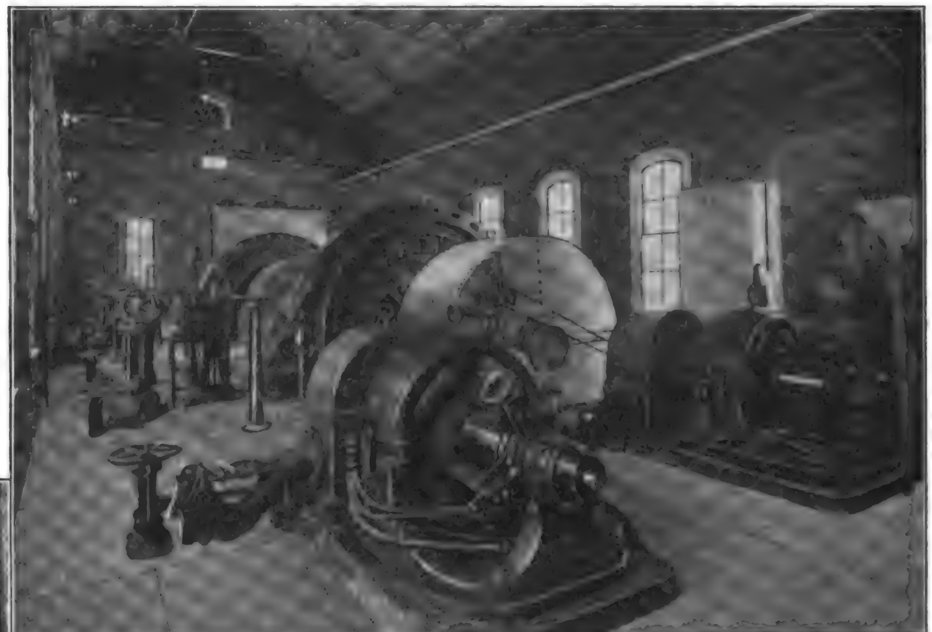

FIG. 11.—INTERIOR OF POWER HOUSE.

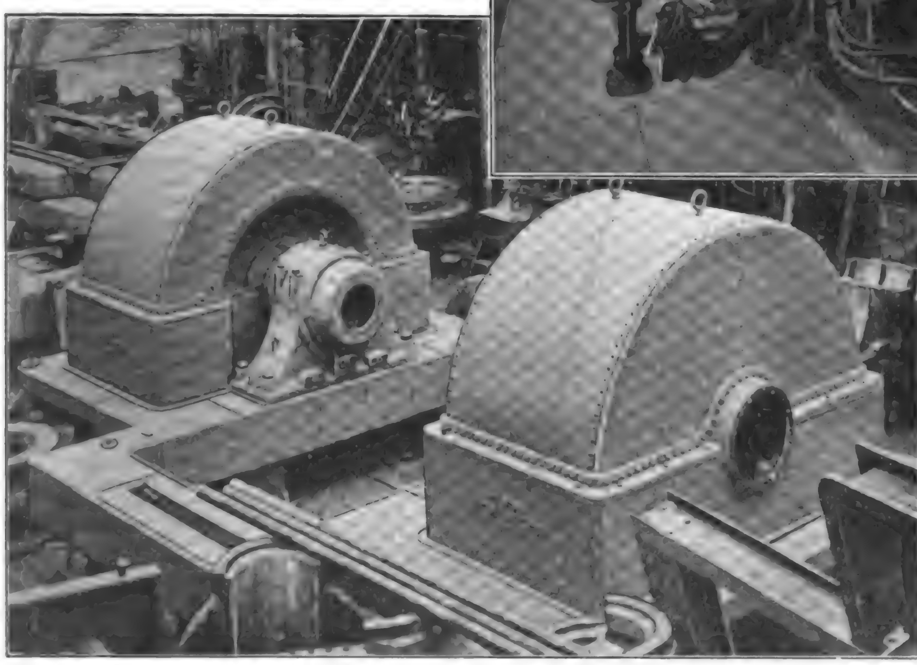

FIG. 10.—SETTING OF WATER WHEELS ON BED PLATE.

The generating equipment consists of two 1500-kw., three-phase, rotating-field, 300-r.p.m., engine-type Westinghouse generators, each being direct driven by the Pelton water wheels being supplied by the branches already mentioned. The rotor of the generator is pressed onto the shaft between the wheels and the shaft is carried in two generator-type, ring-oiling Pelton bearings, the bearing thus being located between each wheel and the rotor. The bearings also have water-cooling compartments, the circulating water used being caught inside the housings in a trough from which the water flows into the compartments by gravity. The whole is mounted on a very substantial cast-iron bed-plate, carrying also the sheet-steel cover housings which suitably enclose the water wheel, pressure pipes, etc.,

within a water-tight chamber. This chamber is entirely open at the bottom into the tail race, which is of massive concrete construction to give solidity to the entire structure. The wheels are constructed of cast-steel plates on which are fitted cast-iron Pelton buckets.

Water is supplied to each wheel through a 7-in. Pelton needle deflecting nozzle, the needle being arranged to regulate the size of the stream, which can be done at any time while the wheels are in operation by the station attendant through the hand wheel and floor stand located near the gate valve. This enables the stream flowing in each wheel-pit to be adjusted for the maximum probable load demand, and automatic regulation is then effected by the governor which raises and lowers the deflecting joint of the nozzle, thus permitting a greater or less quantity of the jet issuing from the nozzle tip to strike the wheels. When the wheels are running at correct speed, the discharge water falls from the buckets without any appreciable energy, and that portion of the stream which may be deflected below the wheel passes clear against suitable steel-lined deflecting plates provided for the purpose. A heavy outside screw and yoke, bronze-mounted gate valve provided with roller bearings is also located back of each nozzle, so that one or both nozzles may be operated at any time. With this arrangement the same high degree of water-wheel efficiency is said to be obtained, down to about 1-10 load, at full load—a very important consideration in most water-wheel plants during low-water season.

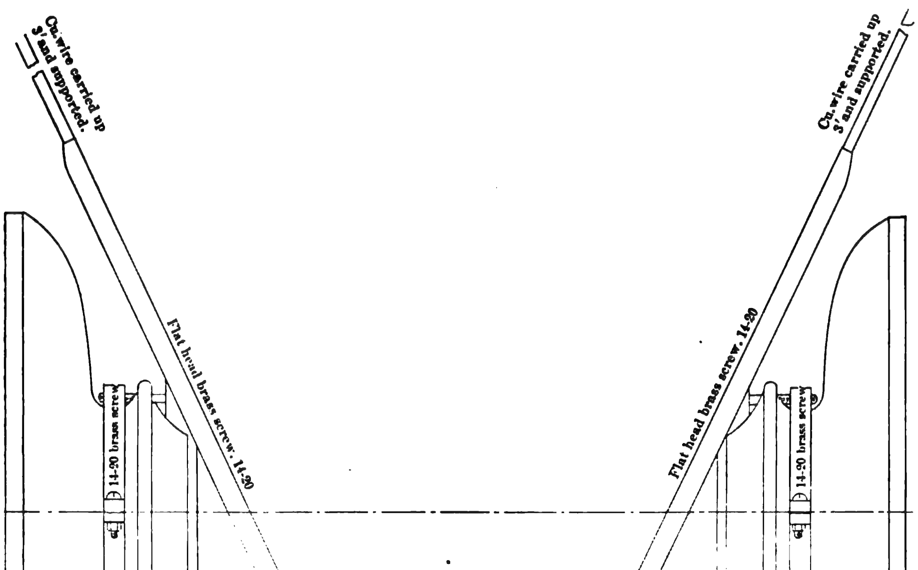

FIG. 12.—ASSEMBLY OF HIGH-TENSION SWITCH.

Automatic governing, as already mentioned, is accomplished through the deflecting of the ball-joint nozzle, which is accomplished through a suitable rock-shaft actuated by a type A Lombard governor. All of the pressure connections are arranged below the floor line, the plant thus presenting a much better appearance and eing susceptible to a much more satisfactory arrangement.

Fig. 10 shows the bed-plate with water-wheel housings and generator-type bearings in position. In one end of each housing and directly opposite the end of the shaft is located a plate-glass covered sight hole from which the operation of the wheel may be observed. Each of the two units has a maximum capacity of 3,000 horsepower.

The exciters are two in number, of 75 kilowatts capacity each, and run at 750 r.p.m. Each is mounted on an independent bed-plate and driven by a special 28-in., 100-h.p. Pelton wheel with bronze buckets to which water is supplied through a needle nozzle and gate valve, similar to that of the large units except that the nozzles are not provided with ball joints. Between the wheels is placed a Type F Lombard governor, arranged so that it can be connected to either unit, as one exciter is sufficient for both generators. Water for the exciter wheels is taken through 5-in. pipes from the large pressure mains, the pipes being connected so that either exciter may be driven from either pipe line. A general view of the generator room is given in Fig. 11.

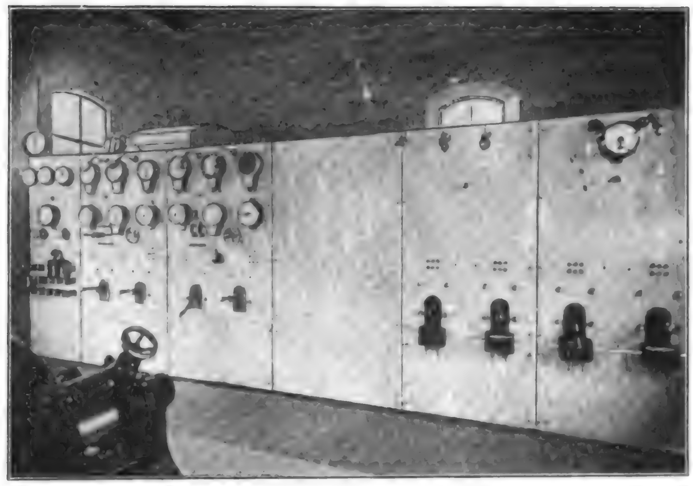

FIG. 13.—SWITCHBOARD IN POWER HOUSE.

The alternators deliver a 2200-volt, 60-cycle, three-phase current and the leads, which are rubber-covered, double-braided, 250,000-circ mil cables, are carried in pairs to the switchboard under the power house floor in 6-in. glazed sewer tile. The switchboard, illustrated in Fig. 13, is built of blue Vermont marble on an angle-iron framework and consists of seven panels 90 inches high. The first panel on the left is used for the exciters and has for its equipment one direct-current voltmeter, two direct-current ammeters, one 5-ampere alternating-current ammeter for use with the water signal for the penstock, two 800-ampere, three-pole, double-throw, quick-break switches, two field rheostats, pilot lamps and plugs for the voltmeters. The next two panels control the 1500-kw. alternators, and the equipment of each consists of three indicating Bristol recording voltmeters, one frequency indicator, one power-factor meter, two 600-ampere single-pole, oil-break switches, one double-throw, two-pole field switch with necessary resistance, synchronizing lamp and voltmeter plugs. The fourth panel is left blank for the addition of a third unit. The next two panels control the circuits leading to the transformers, the equipment of each comprising an 800-ampere, alternating-current ammeter and two 600-ampere, 2200-volt, three-pole, single-throw, Type B interlocking circuit-breakers. On the seventh panel, which controls a 2200-volt circuit running to Placerville, are one triple-pole, double-throw oil switch, three Bristol recording ammeters and one Bristol recording voltmeter.

On a swinging arm at the left end of the switchboard are mounted an indicating voltmeter and a synchroscope. A feature of

FIG. 14.—VIEWS SHOWING DITCHES, PIPE LINES AND FOLSOM MACHINE SHOPS AND SUB-STATION.

the board is a push-button attachment on each generator panel for controlling the governors. The arrangement consists of a direct-current motor controlled by a reversing push-button switch, one button raising the speed as long as pressed, the other lowering it in a similar manner. The low-tension wires in the building used for lighting are run in flexible iron conduits imbedded in the concrete walls.

The transformer installation as a precaution against fire has been located in a separate building placed about 25 ft. distant from the west end of the main station. This building, as shown in Figs. 1 and 2, is also built of concrete in the same general style as the larger structure. The low-tension, 2200-volt leads are carried from the switchboard in the power house to the transformers in 6-in. glazed sewer tiles.

There are seven transformers installed in the building, one of them being for emergencies. Each transformer is of the oil-insulated, water-cooled type and has a capacity of 625 kilowatts. They are designed for connection in delta on the generator 2300-volt side and for star connection on the primary and are provided with taps so as to give line voltages of 60,000, 50,000, 40,000 or 30,000 volts. With a 100 per cent power factor they are guaranteed to have a regulation of 1.7 per cent, and they will operate continually at full load with a raise in temperature not exceeding 40 degrees above the surrounding atmosphere. For convenience in moving them about, each of the transformers is mounted on a steel truck with cast-iron wheels. In order to guard against damage which might be caused by fire in the transformer house, arrangements have been made for emptying the oil in the transformers quickly. A cement-lined sump or pit is located just outside of the building and is connected by means of a 3-in. wrought-iron pipe with the cases of the transformers. This pit will hold the oil from three transformers. A novel device has been designed for attachment to this outlet pipe which will be automatic in action and will not require any attention in case of fire. The arrangement will comprise a 10-in. drum with a 3-in. face, which will be mounted vertically on an extension of the valve stem. A flexible wire cord will be wound around the drum and then carried over a system of small iron pulleys to the outside of the building, where it will be attached to a piece of iron of sufficient weight to unwind the drum and open the valve when allowed to hang free. Normally this weight will be held up about two feet by a hemp cord which will pass into the building and over the transformer case. In case of fire endangering a transformer the cord is burned through, allowing the weight to fall and unwind the drum, thus opening the valve and allowing the oil to run into the sump outside.

The high-tension wires leave the transformer house through 24-in. glazed sewer tiles set at an angle in the end of the building facing the river. From the transformer taps to these large conduits the wires are run on 14-in. porcelain Locke insulators carried on 6-in. x 8-in. timbers running across the house.

The high-tension switching apparatus, as well as the lightning arresters, is installed in the open air in front of the transformer house, being mounted on poles and timbers erected for that purpose.

Leaving the transformer house, the six high-tension wires which comprise the two main transmission circuits first pass through choke coils mounted on a framework on a level with the sewer-pipe conduits. Each of these choke coils is constructed of 24 turns of No. 2 B. & S. gauge hard-drawn copper wire slipped over a length of glazed sewer tile. The coils are about 8 ins. in diameter and the turns are spaced about an inch apart. The whole arrangement is supported by two Locke insulators. This device is simple and inexpensive and has served the purpose very well.

Although there is comparatively little lightning in that section it was deemed advisable to install arresters, the horn type being adopted. The design of this arrester is shown in Fig. 8. It consists of the line wire and ground wire terminals being mounted on four 14-in. Locke insulators as shown, with 5 ft. 9 in. arms, the whole being mounted on the top of an 18 ft. 10 in. x 10 in. timber. The spark gap is arranged so that it can be adjusted for the line voltage by moving the grounded side of the horn back and forth on its cross-arm support, it being secured by two bolts which slide in a slot when loosened. Between the ground side of the horn and the ground a high resistance is used in the shape of a 25-gallon glazed earthen jar filled with water and supported on an insulated platform.

The high-tension switch used on each phase of the circuit is of the fused type with horns for dissipating the arc when the fuse is blown or the switch is pulled. Fig. 12 is a detail of the working parts of the switch. The two knife edges are supported at the ends of a 1-in. glass tube which has at its center a brass attachment that fits into a bayonet socket on the end of the switch handle. The points of the knife edges are connected by the fuse. Each side of the stationary part of the switch consists of brass clips fastened on a curved piece to a standard 14-in. Locke insulator by means of screws and stud to a clamp surrounding the neck of the insulator. The main leads are sweated into the ends of the brass runways at the bottom and carried up a distance of three feet to form the horn. The switches are mounted on a framework with 6-ft. centres and 18 ft. above the ground.

Special precautions have been taken to guard the attendant against accident when operating the switches.. He stands on a platform supported on six Locke insulators and uses a specially constructed handle. This handle is six feet long and has at its upper end the bayonet socket which makes connection with the attachment on the glass rod supporting the switch knife edges. Between the socket and handle grasp is 4½ ft. of 1½-in. round maple treated with a weather-proof varnish. The handle-grasp is made of a piece of heavy glass tubing, 1½ ins. outside diameter, slipped over and firmly glued to a projection of the wooden portion. Covering the glass is a section of the best quality rubber hose, the ends being securely sealed with an insulating compound. At the upper end of the handle-grasp is a shield to keep the attendant from coming in contact with the wooden portion of the handle. The shield consists of a circular piece of plate glass 4½ inches in diameter, with a ⅜-in. hole in the centre that fits over the pole. Above the glass is a fibre washer to protect it from breakage.

The transmission system consists of a double high-tension pole line from the power house to Placerville, where the lines separate, one being carried in a southern and southwestern direction to Stockton, 80 miles distant, while the other is carried nearly west to the vicinity of Folsom, a distance of 30 miles. At present power is being transmitted at 35,000 volts, but the lines are built to carry 60,000 volts and can be operated at that voltage when desired. The present load on the station is about 2000 horse-power. From the power house a low-tension, 2300-volt circuit is carried direct to Placerville, where it is used to supply about 2000 lights. Fig. 6-K shows the three circuits as they leave the power house and are carried across the river on 250-ft. spans and up the bank on the opposite side. The poles used are of seasoned round cedar and vary in length from 35 to 65 feet, according to the lay of the ground. The butts of all poles are treated with a coating of carbolinium avenarius as a precaution against decay. On the double pole line the poles are spaced 180 feet apart and the two lines are separated 25 feet from each other. The cross-arms are of Oregon pine 4¾ ins. x 5¾ ins. and 7 ft. long, and carry two 14-in. Locke No. 320 insulators. The third wire is supported on an insulator of the same size mounted on the top of the pole. The wires are spaced 72 inches from each other on an equilateral triangle. On the double line from the power house to Placerville cross-beams of Oregon pine, 4 ins. x 8 ins., span opposite poles below the cross-arms and carry the three wires of the 2300-volt Placerville circuit and two telephone circuits. After the high-tension lines branch each telephone circuit is carried on a separate cross-arm below the main cross-arm. The pins used are of eucalyptus and are 17 ins. in length for the cross-arm and 19 ins. for the top. As there is a tendency for the pole to split at the top on account of being bored for the pin, the pole-top is wound with eight turns of No. 10 galvanized iron wire. A novel feature has been introduced for the protection of the wooden pins against leakage or static discharge by wrapping the entire length of the exposed portion of the pin in sheet zinc. The additional cost of the zinc is less than three cents per pin and the higher cost of iron pins that are being quite generally recommended is saved. Thus far the results from this construction have been very satisfactory, not a single pin having been lost. In this connection it is very interesting to

notice the exhibit shown in Fig. 18. This shows a pole-top that had been burned away and the insulator and pin. When the pole was found it had been burned as shown, but the insulator and pin were still in position, being held there evidently by the winding of galvanized wire, while the zinc wrapping had protected the pin and thus kept the insulator from falling. The lesson to be drawn from this exhibit is obvious. The entire line to Stockton consists of No. 1 B. & S. gauge seven-strand bare aluminum wire, weight 401 pounds to the mile. Soft aluminum wire is used for the wires and the poles are set 180 ft. apart. For the Folsom line No. 4 medium hard-drawn copper wire has been used with No. 6 annealed copper tie wires. On account of the greater weight of the wire the poles on this line are set 135 ft. apart. The company installed both aluminum and copper lines so that it could observe the working results of both under similar conditions and determine which was the best material to use for future extensions. Thus far the wires have not been in operation long enough to give conclusive results.

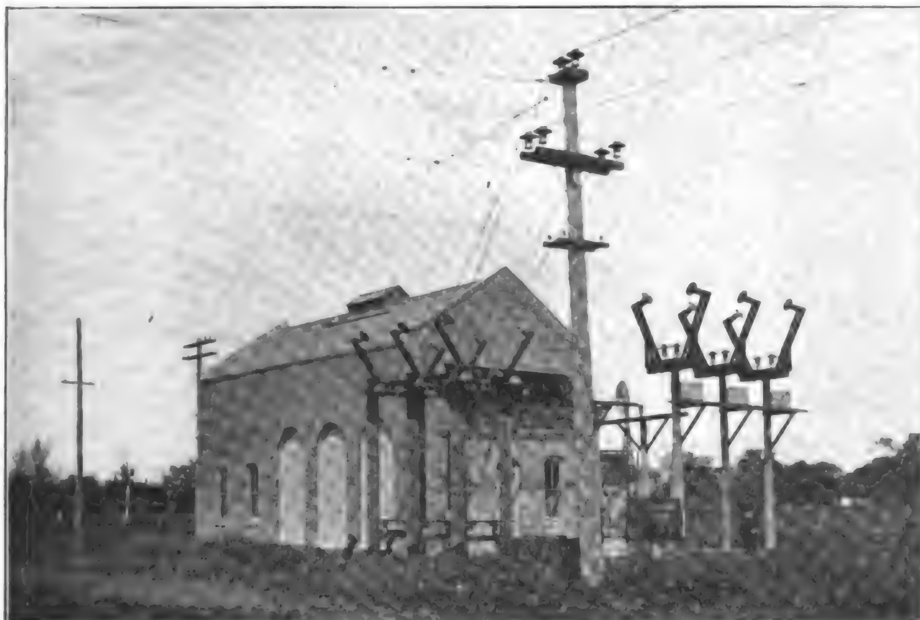

FIG. 15.—STOCKTON SUB-STATION.

FIG. 16.—JENNY LIND SUB-STATION.

FIG. 17.—HIGH-TENSION END OF FOLSOM SUB-STATION.

Fig. 14-E is a view of the company's Folsom sub-station and shows how the 11,000-volt and 2200-volt secondary wires are carried up and over a steam railroad track and two pole lines of another transmission company. The poles are of sufficient height and close enough together so that a broken wire will not come in contact with a train, and further protection is provided by a wire net between the poles and above the track.

At the Stockton terminus of the 80-mile, high-tension transmission is the neat brick sub-station shown in Fig. 15. This view also illustrates the high-tension switching apparatus and lightning arresters, which are of the same types as those shown at the power house. The sub-station is equipped with step-down transformers and as a rule does not require an attendant. There are installed in the station three 150-kw. and three 300-kw., oil-insulated, water-cooled transformers. These transformers are constructed with taps for 30,000 to 60,000 volts on the primary and 2200 volts on the secondary, with an allowable variation of 5 per cent above or below. The switchboard, Fig. 20, has three panels—one for the transformer and two for the secondary feeders, equipped with oil switches, lightning arresters, instruments, etc.

In Stockton the company supplies a commercial service of about 6000 incandescent lights and about 300-horse-power in motors. It has only been operating since early in 1904, and is competing with an old-established company. In the business district of the city the company is placing its commercial three-wire, 220-volt secondaries underground in Edison tubing.

A feature of the sub-station, as well as of the power-house, is the precaution taken in installing the telephone instruments. In Fig. 19 is shown the apparatus in the Stockton station. The telephone is mounted on the upright portion of a platform which is insulated from the concrete floor by glass insulators. A person talking has to stand on this platform in order to reach the instrument. The two line wires terminate above the telephone, as shown, in special fuses mounted on slate panels that are in turn insulated from the wall. A knife switch with a long break is placed above each fuse so that the line can be cut out when the fuse is replaced. The telephone line from the power house passes through this sub-station and then to the company's office in the city and the wiring is arranged so that the talking circuit may be cut out when no one is at the station. Knife switches are provided for cutting the talking circuit in and for cutting out either the power house or the office end of the line. No trouble is had in talking over the 80-mile circuit to the power house or over the entire 110 miles to Folsom. In the power house a special concrete booth has been built for the telephone and the latter is also insulated in the same manner as at the Stockton sub-station.

At various points along the Stockton transmission line the company has been able to develop a good business in the supplying of power. This line runs through some of the richest mining camps in the Mother Lode and the outlook for further development is very good. An electric railway is to be built from Ione to Jackson and Sutter

Creek and the American River Electric Company has the contract for supplying the necessary power.

A spur of the line runs to the Jenny Lind mining section, where the sub-station shown in Fig. 16 has been erected to take care of the business. The equipment consists of three 100-kw. transformers which reduce the voltage to 2200 or 4400 volts, the latter being used. The power supplied from this station is utilized for the operation of gold dredging plants. At Nashville a similar sub-station has been installed, the power in that case being used for quartz mining.

FIG. 18.—BURNED POLE TOP.

The Folsom sub-station, at which the 30-mile, high-tension line terminates, is constructed of corrugated iron and covered with P. & B. roofing. The interior of the sub-station is shown in Fig. 21. The equipment consists of four (one spare) 300-kw. transformers stepping-down from 30,000 to 2,200 or 4,400 volts and three 100-kw. transformers stepping-down to 11,000 volts. The entire output of this station is sold to the Folsom Development Company, a corporation which has entered extensively and systematically into the gold dredging business in that vicinity. This company has purchased 18,000 acres of land in that section; has two dredges in operation near Folsom; is operating two or three at a point four miles below, and is planning to build ten or a dozen more in the near future. As this phase of electric power development is an interesting one, some mention will be paid to it.

In Figs. 22 and 23 are shown two of the Folsom Development Company's dredgers at work. These dredgers are built on the spot, a pit being excavated for the purpose, and if the land is not near enough to the river to give water to float the boat, water is pumped into the pit. The gold-bearing soil is a gravel deposit that has been washed down in old river channels from the rich Mother Lode district farther up on the mountains. It has only been since electric power could be obtained at a cheap rate that it has been profitable to work this ground, but judging from the investments that are being made now by this and other companies in the way of expensive machinery installations, the business must be a decidedly profitable one. The mining has been reduced almost to a science so that there is little if any chance in the work. The entire land is surveyed and divided into plots 50 ft. square and in the center of each plot a prospect is drilled by sinking a 6-in. shaft to hard pan. All the gravel and sand that is removed is carefully measured and its gold-bearing properties determined. If it is found that the percentage of gold is high enough to make dredging profitable the plot is reserved for working. Then, as mentioned before, a large pit is dug and the dredger built complete on the spot. Both dredgers illustrated in Figs. 22 and 23 are of the type constructed by the Bucyrus Co., of Milwaukee, but the engineers of the Folsom Development Company, who have been working on the problem for several years, have designed a dredge which is said to suit the local conditions better and hereafter the company will build all this machinery in its own shops and construct the dredgers complete. The gold-bearing strata varies from 10 to 50 ft. in depth and the boats are designed to work to those depths. The earth is picked up by chain buckets, each bucket having a capacity of 5 cu. ft. The dredgers are generally rated by the capacity of the buckets, and a 5-ft. bucket dredger will dig from 50,000 to 75,000 cu. yds. of material per month. The earth is raised by the buckets and deposited in a shaker or screening device which shakes the rocks loose from the dirt and small gravel. The rocks are deposited on an endless conveyor belt which delivers them at some distance behind the dredger on ground that has been worked. The soil is washed through shakers and riffles, the gold being deposited on saving tables, while the sand is forced out at the rear through a pipe by means of a centrifugal pump.

In dredger No. 2 of the Folsom Co., illustrated in Fig. 23, a 100-h.p., variable-speed, induction motor is used to drive by means of a large belt the digging buckets and the drum for raising and lowering the buckets. A 50-h.p., 2200-volt motor is direct connected to the shafts of two Goth centrifugal pumps which are used for pumping water onto the riffles and shakers for washing the earth. On the deck of the dredger is a 30-h.p., 440-volt motor which drives the shaker and also operates the large rubber rock conveyor belt that is seen extending in the rear of the boat. A 20-h.p., 440-volt, variable-speed motor is used for driving the winches with which the boat is moved from one position to another and which are also used for raising the spuds.

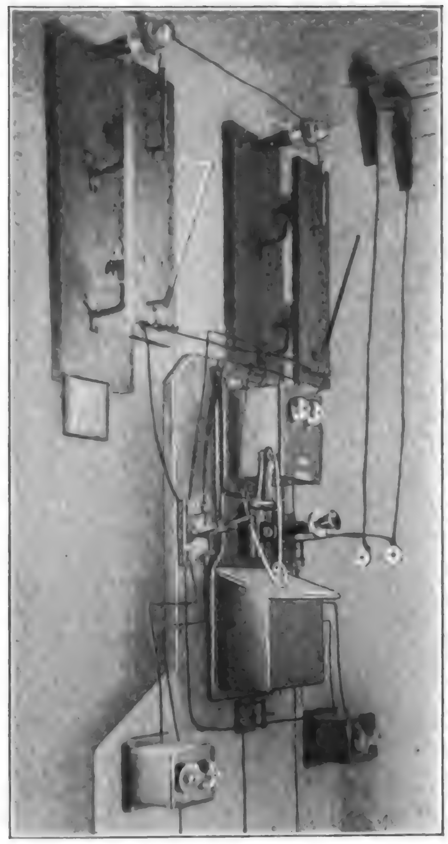

FIG. 19.—PROTECTED TELEPHONE IN STOCKTON SUB-STATION.

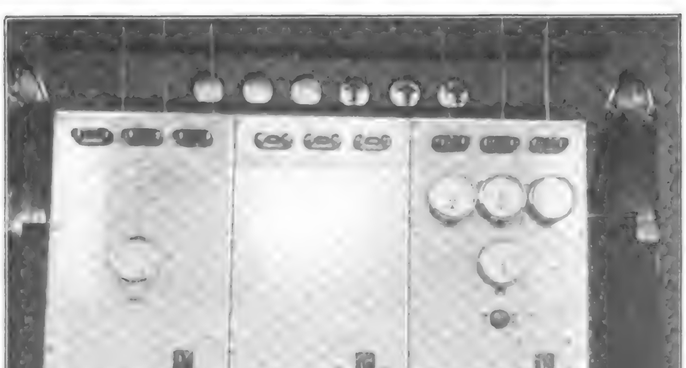

FIG. 20.—SWITCHBOARD IN STOCKTON SUB-STATION.

FIG. 21.—INTERIOR OF FOLSOM SUB-STATION.

There are two of these spuds at the rear corners of the boat and they are used to hold the dredger in position while it is operating. One spud is built of steel 50 ft. long and weighs about eighteen tons, and the other is of wood and weighs about ten tons. A 30-h.p., 440-volt motor is connected to a centrifugal pump which is used to force the sand discharged from the screws through the pipe on the conveyor ladder. There is a 3-h.p. motor that drives a centrifugal pump used in priming the large pump used for washing the decks and similar purposes. This equipment of six motors, aggregating 233 horsepower, is controlled and operated from a controller or switch room located at one corner of the upper deck. The buckets and winches are operated from this room by means of levers and a specially wound controller. A lighting switchboard located there controls the 125 16-c.p. incandescent lights that are used to illuminate the boat and surroundings at night, as the dredging work is carried on night and day. Five-lamp clusters are used with reflectors for the exterior lighting. Arc lamps of ordinary construction cannot be used on the dredgers on account of the constant vibration of the boat.

The present accepted construction of the dredgers call for the location of the transformers on the boat, but on account of the insurance regulations a special sheet-iron-lined compartment is built on the outside of the boat to contain them. The transformer room on No. 2 dredger contains three 30-kw. Westinghouse transformers which reduce the voltage from 2200 to 440 volts. All the motors on this boat are of General Electric manufacture. Dredge No. 1, illustrated in Fig. 22 has equipment similar to that of No. 2, with the addition of a 10-h.p. motor driving a centrifugal pump for discharging water into the hopper into which the buckets empty.

A very important feature of the electrical operation of the dredgers is the cable which is used to transmit the power from the end of the pole line to the bank of transformers on the boat. After a good deal of experimenting with various kinds, the electrical department of the company has adopted a standard cable which consists of three No. 2 double rubber-covered 3/32-in. insulation wires pulled into a 1¼-in. heavy rubber hose. The joints of the hose are carefully cemented and the cable is then tested to 10,000 volts. This cable has proved very satisfactory, and although generally supported above the water by barrels it can be safely used under water. The extent to which the Folsom Development Company is carrying on its dredging work has warranted it in erecting a large machine shop, offices, etc., on the ground, a general view of which is shown in Fig. 14-D. At these shops everything in the way of machine work for new dredgers as well as repairs on those in operation is being caried on, the foundry work being done in Sacramento. The machine shop is well equipped with heavy tools and is operated electrically, seven motors ranging from 3 to 30 horsepower being used for the purpose. A portion of the shop is also fitted up for electrical repair work. All the electrical work of the company, including that on the dredgers and in the shops, is in direct charge of Mr. A. B. Coon, electrical engineer of the company.

FIG. 24.—PORTABLE SUB-STATION AT FOLSOM.

An allied corporation has in operation near Folsom a dredge in connection with which is used the unique portable sub-station illustrated in Fig. 24. This transformer house is mounted on a street-car truck and is moved around on a temporary track as frequently as is necessary. The building contains three 50-kw. Westinghouse transformers delta connected. They reduce the voltage from 11,000 to 1200 volts. The high-tension fuses and a set of Westinghouse low-equivalent lightning arresters can be seen in the opened compartments at the end of the station. The current is carried from this sub-station to the dredger at 1200 volts in a flexible waterproof cable which contains three conductors. The dredge is a typical New Zealand gold dredge electrically operated. The boat was built by the Risdon Iron Works, of San Francisco, and placed in operation about two years ago. The largest motor on the boat is a 75-h.p. type F Westinghouse variable-speed induction motor which drives the digging buckets. The pump which supplies the water for washing the gravel is driven by a 50-h.p. Westinghouse type C constant-speed motor. These two motors are operated at 1200 volts. The smaller motors on the boat are one 20-h.p., constant-speed machine driving the conveyor, two variable-speed motors operating the two winches and one 1-h.p. motor driving a small pump for

FIG. 22.—DREDGE NO. I. OF THE FOLSOM DEVELOPMENT COMPANY.

FIG. 23.—DREDGE NO. 2 OF THE FOLSOM DEVELOPMENT COMPANY.

fire purposes and for priming the large pumps. The small motors are operated at 440 volts. A bank of three 25-kw. Westinghouse type O. D. transformers are used on the boat for reducing the voltage from 1200 to 440 volts and also to 110 volts for lighting purposes. About 75 incandescents are employed for lighting on the boat. The capacity of the buckets on this dredge is five cu. ft. each and about fourteen buckets are dumped per minute. This boat has been in almost constant operation since being placed in commission two years ago.

The Folsom Company has in connection with its plant a portable compressor plant, consisting of a 10-h.p., 440-volt motor belted to a compressor. This outfit is enclosed and mounted on a wagon so that it can be readily hauled to any desired spot and used for drilling, repair work, etc.

In addition to the extensive field for power furnished by the gold dredging and mining companies, the American River Electric Company expects to develop a good business in irrigation pumping. Its lines tap a rich agricultural section where water can be easily obtained at a depth of about twenty feet, and with cheap electric power there is every reason to expect that the development along this line will be profitable to the company as well as the farmer.

Credit for the design and erection of the American River Electric Company's plant is due to Mr. A. M. Hunt, of San Francisco, recently of the Engineering Offices and also recent general manager of the Independent Electric Light & Power Company of that city. The original features of the system that have been mentioned are practically of Mr. Hunt's design. The entire plant was erected and put in successful operation in about six months, which is an exceptionally short time when the engineering and practical difficulties are considered. Mr. Hunt received very valuable assistance from Mr. B. C. Condit who had active charge of the construction of the plant and is now directing the further operation and development of the system, through his position as superintendent of the American River Electric Company. Appreciation is due both of these gentlemen, as well as to Mr. Mortimer Fleishhacker, of San Francisco, the president of the company, for their courtesy and kindness in assisting the writer in the preparation of the foregoing description.

Municipal Ownership in Great Britain.—A report from the United States Consul at Liverpool states that there is in Great Britain an unmistakable diminution of the tendency toward the municipal ownership of industries. Very little is heard now of new movements in that direction, and the thoughts of the municipalities are more directed toward increasing economy of management of the public utilities which have been acquired. Probably the reaction against municipal ownership may be largely due to the increase of $1,252,000,000 in local indebtedness in Great Britain in 28 years, and the fact that the returns from the whole mass of municipal investment have not been anything like as high as was expected.

REVISION OF THE NATIONAL ELECTRIC CODE.

At the annual meeting of the Electrical Committee of the Underwriters' National Electric Association, held in New York December 7 and 8, the Code of Rules and Requirements for the installation of electric wiring and apparatus was revised in several important particulars and a good many minor changes were made. The most radical suggestions for amendments—those which had aroused the central station men and contractors to a mental state approaching indignant resentment—were rejected with scant discussion and by unanimous vote.

The report of the committee on car wiring was accepted; this recommended that all proposed amendments to the rules on this subject be referred to the Joint Conference Committee for consideration, and that no material change be made in Rule 32 until at least one year has elapsed and the rule has had a fair trial.

The reports of the Committee on Switches and Cut-Outs and the Committee on Test Specifications for Rubber-Covered Wires were also accepted. The Switch and Cut-Out Committee recommended raising the melting point of enclosed fuses to 25 per cent. above the continuous carrying capacity; also the amendment of Rule 1 by adding a section requiring terminal blocks on all electrical machines to be made of approved fire-proof insulating material, such as slate, porcelain or marble.

The Committee on Rubber-Covered Wires recommended that the rules be amended to require each foot of the rubber covering to withstand for five minutes the application of an e.m.f. proportional to the two-thirds power of the thickness of the insulation for coverings of 1/16 inch and over; below 1/16 inch, empirical test voltages of 3000 volts per 1/64 inch are specified.

The report of the Underwriters' Laboratories, recommending no change in present requirements for insulating joints, was adopted, but their suggestion for the omission of insulating joints on grounded systems was referred to a special committee for consideration, on the motion of Mr. Arthur Williams of the New York Edison Company.

The rule regarding leads from central station generators to switchboards was amended by adding a fine-print note to the effect that such leads may be put in a conduit, a smooth runway being desirable, but that lead-covered cable may be used without any conduit if the lead sheath be not allowed in contact with any object tending to abrade it.

A suggestion for an amendment requiring the casings of all transformers in central and sub-stations to be grounded with conductors equal in carrying capacity to the largest fuse in the high-optential circuit was regarded favorably by the committee, but upon explanation by Mr. Alex. Dow, of Detroit, that in many cases there were no fuses in the high-potential circuit and the rule would, in those cases, be abortive the suggestion was referred to a special committee for consideration.

The agitation concerning stringent rules for aerial conductors came to naught. Two definite suggestions were offered: one for a rule requiring conductors "attached to or in close proximity to buildings" not to be installed "so as to interfere with the work of the fire department"; the other for a rule prohibiting the placing of telegraph, telephone and similar wires on the same poles with electric light or power wires, and the stringing of such wires so as to pass above or below heavy-current wires except where accidental contact is prevented by means of suspension or screening wires, as already provided in the Code. These suggestions were promptly rejected.

The rule regarding the entrance of low-potential circuits into buildings was amended to allow such service wires to be brought in through a single iron conduit, the outer end of which must be carried downward and sealed to prevent the entrance of moisture. The outer end must also be kept at least 12 inches from frame buildings or frame portions of other buildings.

The rule on wooden molding was amended to specify a tongue not less than ½ inch thick between the conductors, and exterior walls not less than ⅜ inch thick under the grooves and ¼ inch thick at the sides.

The following are among the minor changes adopted:

Transformers must not be mounted on frame buildings or frame portions of other buildings.

Double-throw knife switches may be mounted to throw either horizontally or vertically, as preferred.

Wires run in unfinished attics are to be classed as "concealed" and those run near water tanks or pipes are considered as exposed to moisture. Wires in attics, excepting in large churches or similar buildings, must be run between or through the joists and not on top of them.

On switchboards, spacings approved for 250 volts direct current are also approved for 500 volts alternating (instead of 440, as before).

The rule on arc lamp hanger boards is restricted to series arc lamps.

No Municipal Plant for Milwaukee.—The faction favoring a municipal lighting plant for the city has again lost in a vote before the City Council. Since the first defeat of the measure in the council, about a month ago, the question has been the occasion of several mass meetings and much heated discussion. One councilman, in order to obtain the opinion of his constituents, mailed to each of them a reply postal card. After the defeat of the measure for the issue of $150,000 bonds for the lighting plant, President John I. Beggs, of the Milwaukee Electric Railway & Light Company, offered to light the city at a rate equal to that which it is figured it costs the city of Detroit for lighting by means of its municipal plant. This communication was referred to the Committee on Street Lights and Judiciary.

P PE JOINTS, GASKETS AND LEAKS.

BY R. T. STROHM.

A leaky joint in a steam pipe may be the cause of a considerable loss during a year of continuous operation of a steam plant. More than this, such a leak never grows less when left to itself. Steam, under high pressure, containing entrained

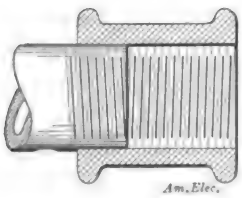

FIG. 1.

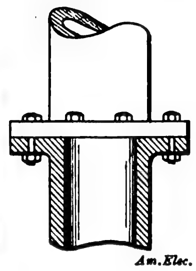

FIG. 2.

moisture, has an erosive effect when escaping from an orifice, which tends to increase the size of the opening. A 1/8-inch hole in a main carrying 125 pounds steam pressure will permit the escape of 88 pounds of steam in an hour. This would be equivalent to 2100 pounds per day of 24 hours. Assuming that it requires a pound of coal to evaporate 7 pounds of water, and that the plant is operated 300 days per year, the effect of the leak is to throw away 45 tons of coal a year.

But this is not the only drawback. To the casual observer, a hissing leak in a steam pipe gives the impression of carelessness or inability on the part of the engineer. Such a verdict may be extremely unjust. All other appliances in the plant may be in practically perfect condition, and the general appearance may be exceedingly neat and trim. Yet the leaking joint will spoil the effect of the whole. Perhaps the leak has just shown itself, and there has been no time, in the press of more urgent affairs, to care for the matter. Or, perhaps, it is not easily accessible, so that its repair must wait a convenient time.

There is still another consideration. All well-regulated plants have their steam pipes protected by non-conducting coverings, to prevent loss of heat by convection and radiation. Most of these coverings are made of asbestos and magnesia, in varying proportions. Hence, when a leak occurs, the condensation resulting from the escaping steam may saturate the covering, rendering it soggy and of little value as an insulator.

Tight joints may be secured in a number of ways, but they always depend upon the materials and the workmanship. A poor workman may fail to secure a tight joint with the very best materials at hand, while a skilled engineer may succeed with a poor quality of materials.

The most common form of joint is the screwed joint, like that shown in Fig. 1. Owing to continued use, the steam fitter's pipe dies may become worn and broken, so as to cut an imperfect thread. Then, when the pipe is put together, a leak develops at the imperfect joint. Or, perhaps, the thread may be cut crooked, because of carelessness or ignorance on the part of the workman, which would likewise result in a leak. The presence of dirt on the threads, preventing their coming into perfect contact, is liable to develop a leak. Hence, to make a good joint, the threads must be cut accurately and be wiped clean before screwing together.

In order to make certain that no leaks should occur, even if the joint was somewhat imperfect, it used to be the general practice to give the threaded portion of the pipe a coat of white lead or red lead. This mixture filled all the interstices between the threads and hardened effectually preventing the escape of any fluids conveyed through the pipe. But this is no longer considered good practice. For, while the joint thus formed was permanent, it would not allow the pipes to be taken apart readily, when such procedure became necessary. The lead on the threads seemed to cement them together, and after the joint had stood for some time it was practically impossible to unscrew the pipes. Frequently the pipe would split and crush under the torsional stress of the wrench without beginning to loosen the joint. In many instances it was found necessary to smash the fittings in order to take down several lengths of the pipe which had been put up with red lead joints. This is no longer necessary. If a

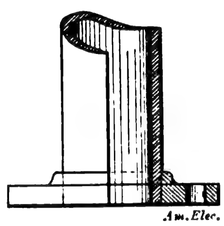

FIG. 3.

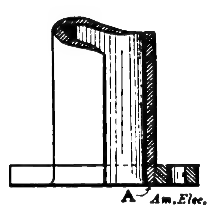

FIG. 4.

good grade of cylinder oil is mixed with graphite until a fairly thick paste is formed, and the threads are coated with this paste, the joint will not only remain tight, but it can be readily taken apart, whenever necessary, without undue labor or damage to the fittings. A low-grade cylinder oil, or a light lubricating oil should not be used in making this paste, because it will carbonize, especially if the steam pressure in the pipe is high, and cause the joint to seize as in the case of the red lead.

Another very common kind of joint is the flange joint, consisting of two flanges held together by bolts, as in Fig. 2. There is a variety of methods by which the pipe may be secured to the flange, depending upon the material and the service to which it is to be put. In the case of cast-iron pipe, the flange is cast in one piece with the pipe, as in the sectional view, Fig. 2. However, it is also common to find cast-iron flanges fitted to wrought-iron pipes by means of a screwed joint as shown in Fig. 3. This is a form much used for comparatively small pipes. A stronger form is illustrated in Fig. 4. Here, a wrought-iron or steel flange is used, and after the pipe is screwed in, its end is riveted over as at *A*, which not only makes a tight joint, but also renders the pipe less liable to fail by stripping off the flange. For large pipes and high steam pressures, the flange is frequently secured to the pipe by riveting, as in Fig. 5, both the flange and the pipe being either of wrought-iron or steel. The end of the pipe is also peened over so as to secure tightness of the joint.

As a usual thing, the faces of the flanges which come together to form the joint are not smooth, and if put together in this condition, a tight joint could not be obtained. Hence, in cases of this kind, gaskets of some yielding material, softer than the metal flanges, are placed between the latter. When the bolts are tightened and the flanges drawn together, this softer material is compressed and crushed, conforming itself to the inequalities of the two surfaces and forming a bond between them which prevents leakage.

Sheet rubber is very extensively used as a material for gaskets. The shape of the gasket is scribed on the surface of the rubber, after which it is readily cut out with a sharp knife. Some engineers use a special form of cutter for cutting out circular gaskets. It consists of a tram having a pivot point and two movable knives which can be set at any desired distance from each other as from the pivot. The distance between the knives determines the width of the gasket, and the distance from the pivot to the nearest knife determines the size of hole in the gasket. Since gasket rubber is sold in rectangular sheets, there is some unavoidable waste in cutting circular gaskets. However, this may be greatly lessened by proper care. The odd corners which are left over will furnish small gaskets for pipe unions, and the circular pieces cut from the centers of large gaskets may be used to give smaller ones for smaller flanges. It will be found that wetting the knife makes the cutting much easier.

On a steam line which carries a lowered pressure during the night, or on any line in which the steam pressure varies, the gaskets are subjected to alternate heating and cooling. The expansion and contraction of the pipe sections twist and strain the joints, and tend to open them. Hence, it is not surprising that joints eventually begin to leak. The heat causes the rubber to harden, and the straining of the joints cracks it, resulting in leakage. The best makes of sheet rubber for gaskets are those

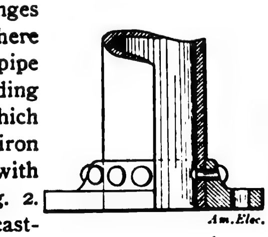

FIG. 5.

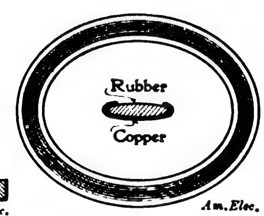

FIG. 6.

which do not lose their elasticity readily and are not easily affected by changes of temperature.

The fact that soft rubber is affected by heat has led to the use of other materials for gaskets, or combinations of other materials with rubber. One form is illustrated in Fig. 6. It consists of a circular rubber ring encased in a shell of soft, annealed copper. Both are easily compressed and conform to the surfaces of the flanges, while

the elasticity of the combination is a point much in its favor. The copper casing adds greatly to its strength, also, making it less liable to blow out under high pressures. This gasket is placed inside the bolt circle.

The ability of asbestos to resist the action of heat has led to its adoption as a gasket material. Being of a fibrous nature it is woven into sheets from which the gaskets are cut, ready to use. For pipe lines conveying high-pressure or superheated steam, the asbestos gasket gives excellent service,

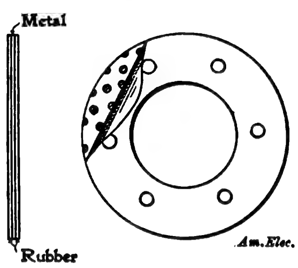

FIG. 7.

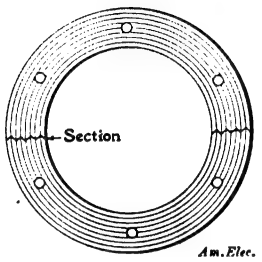

FIG. 8.

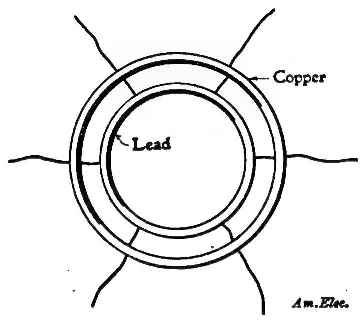

FIG. 9.

and there are instances on record where it has been in use for four years without a sign of leakage.

In some of the sheet packings an insertion of cloth between the layers of rubber is employed to give additional strength. In others, a sheet of soft metal, perforated with numerous small holes, is used instead of the cloth. A gasket with perforated metal insertion is shown in Fig. 7. For extremely high pressures, however, metallic gaskets should be used. One form, composed wholly of metal, is illustrated by Fig. 8. It is an annular ring of copper, corrugated as shown by the section profile line. This gives it greater elasticity and enables it to adjust itself to the surfaces to better advantage than if it were simply a flat plate. Another very simple form of metallic gasket is that shown in Fig. 9. It consists of two circles of round wire, the outer one being of copper and the inner one of lead. They are kept concentric by means of short wires soldered to each, the wires being extended several inches be-

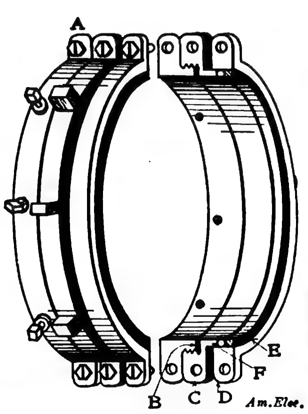

FIG. 10.

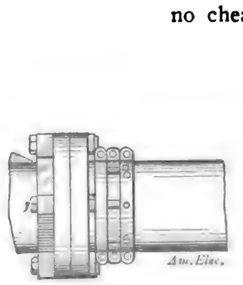

FIG. 10-A.

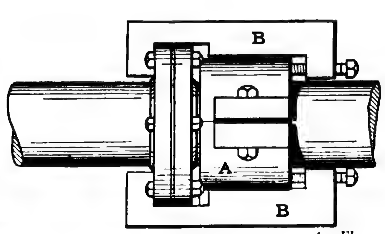

FIG. 11.

yond the outer ring. Besides holding the two circles together, these are used to center the gasket on the face of the flange by wrapping them around the bolts. The rings being of soft wire, they readily flatten under pressure, and thus spread over sufficient surface to produce a tight joint.

There is this disadvantage, however, in the use of a metallic packing. The coefficients of expansion of the soft metal and of the pipe are not the same, so that while the joint may be perfectly tight under full pressure, it leaks when the pressure is reduced, due to unequal expansion. This objection is not sustained, though, if the joint is kept under constant steam pressure.

The asbestos gasket is open to the objection that it softens by the absorption of water, and causes trouble by blowing out. All in all, the rubber gasket, with or without insertion, seems to be the standard. If properly "followed up" it will give excellent service. By "following up" is meant the tightening of the flange bolts after the gasket has been in service a short time. That is, if a joint is made in the morning, the nuts are screwed up tight enough to prevent leakage. During the day, the gasket becomes thinner, due to the high compressive stress, and attains more of a permanent set. In the evening, then, the nuts should again be tightened a little, to take up this alteration in thickness, and the process repeated, if necessary, the next day. A point will soon be reached at which there will be no further change, and under these conditions the joint may be left to itself with the expectation of reasonably long service.

Paper has been used to form gaskets, where the faces of the flanges were planed or turned, and so came together true and parallel. A piece of paper flour sack or tough wrapping paper, cut to the required form and given a coating of cylinder oil, has been found to make a durable and effective joint, and certainly there could be no cheaper. This form of gasket may be used on the planed joints of small steam pumps and steam engines. The purpose of the cylinder oil is to prevent destruction of the paper when subjected to high steam pressure.

In all flange joints except those with planed or turned faces, the surfaces of the flanges should be scored by a number of shallow concentric grooves. The gasket is compressed into these indentations, making it less liable to blow out.

The liability to leakage of screwed pipe joints has already been mentioned. These leaks are apt to develop at any time, and it is often absolutely impracticable to shut off the pressure to repair the defect. To enable immediate repairs to be made in such cases, there has arisen a class of devices known as pipe joint clamps. One form is illustrated in Fig. 10, showing the appearance both off the pipe and on it. There are three rings, made in halves and held together by screws. The first, *A*, is firmly clamped to the pipe by means of the set screws spaced at equal distances around it. It has a threaded lip *B*, which engages with the threaded portion of the collar *C*. Both *A* and *C* are of such internal diameter as to fit snugly to the pipe. The collar *D* is considerably larger inside, and contains a ring of packing *E* between itself and the pipe flange. The collar *A* being held tightly by the set screws, and the ring *C* being turned by means of a spanner, the lug *F* forces the packing toward the flange. Since the collar *D* prevents the packing from expanding, it is forced firmly against the pipe fitting and effectually stops the leak.

Where a flange joint is employed and a leak occurs between the pipe and the flange, the arrangement shown in Fig. 11 may be used to advantage. A collar *A*, made in halves, is put in place on the pipe, close to the flange. A piece of sheet rubber is held between it and the pipe, the rubber pro-

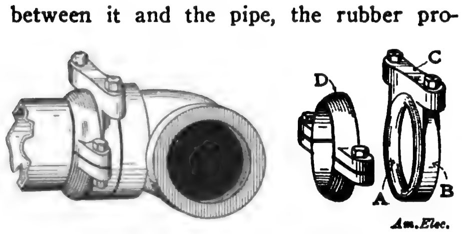

FIG. 12.

jecting a quarter of an inch or more toward the flange, and being flared so as to fully cover the joint. Then three clamps *B* are put in position and the set screws are tightened, forcing the packing hard against the flange, and thus preventing further escape of steam.

An extremely simple form of pipe clamp is illustrated in Fig. 12. The packing ring *A* is placed around the pipe, against the elbow or tee in which the leak has occurred. Then the flexible U-shaped band *B* is placed over it. The ends of this strap are threaded, and are passed upward through the yoke *C*, which is pressed down on the packing ring. Then the nuts are put on, and screwed up just enough to hold the packing in place. The split collar *D* is next firmly clamped around the pipe, against the packing. Finally, the nuts on the strap ends are tightened, and the packing, compressed between the yoke, the strap and the pipe, and unable to expand on the side next the collar *D*, is forced into the angle between the pipe and the edge of the fitting, making a perfect seal.

A WHOLE TOWN HEATED BY ELECTRICITY.

BY GEORGE E. WALSH.

The town of Davos, in the Swiss Alps, is famous for its dry, healthful climate, and in the winter season thousands of tourists and health-seekers sojourn there. It is situated at a high altitude, so that its winters are cold, but dry and invigorating, and its air so pure that two great sanitariums are occupied by people in search of health or recreation, or both. The question of heating the town of Davos and its two important sanitariums has vexed the local authorities for many years. The fear of contaminating the pure, dry air of the mountain resort with smoke and ashes finally led them to adopt electricity for all purposes—heating, cooking, lighting and power. There is a fixed population of some 3000 to-day, and a visiting population in winter of nearly as many more.

The question of the best form of heat for the sanitarium patients was also considered from a medical point of view. The physicians condemned gas and coal stoves on account of the unhealthy odors emitted by them, and steam heat for the houses and hotels was considered unhealthful also. Electricity was finally adopted as the best for all concerned, provided that it could be obtained at a reasonable cost.

The electricity for heating the town is supplied from power houses on the two streams, Landwasser and Albula, situated nearly ten miles away, where there is a fall of nearly 1300 feet. There is sufficient water power on these two streams to heat and light the whole town, and the final completion of the plant has enabled every inhabitant to use electricity for every household necessity.

The question of the amount of heat required to do all the cooking, heating and lighting of the town was one that could not be easily answered in advance, for there was no existing example for comparison. The town covers a district about two miles long and half a mile wide. In this space the large hotels and sanitariums are grouped.

A central station containing five units of 3000 horse-power each was orginally built with the expectation of furnishing all the electricity needed; but provisions were soon made for extensions. Each turbine is direct-coupled to two three-phase alternators, giving 8000 volts each, the two being coupled in a series to furnish 16,000 volts to the lines.

The heating of the houses was the most perplexing problem. The heating radiators consist of resistance coils covered by suitable enamel, and so placed in the rooms that the distribution of the heat is thorough. The cooking stoves consist of small alternating-current transformers that induce local currents in their bases. The heating was based upon the estimate that about 253 watt-hours per day would be needed for about 12 cubic feet of apartments. This amount of energy proved too high on warm winter days, and rather too low on very cold days; but the average throughout the year was not much astray.

The question of cost was vital. The annual expenses of the whole plant were found to be, the first year, about 830,000 francs, and the total consumption of energy 25,000,000 kilowatt-hours. At this ratio the cost of each kilowatt-hour averaged 3.3 centimes. This cost for heating is not excessive, although a little high for cooking purposes. However, the average for heating, cooking and lighting was considered reasonable, and the advantages obtained more than offset any slight increase in cost of the various classes of service. Those who have visited Davos since the installation state that the heating of the rooms is superior to anything before attempted, and the perfect temperature regulation obtained makes it immeasurably superior to coal or steam heat. The local physicians claim that the electrical heating of the houses and sanitariums is proving almost as beneficial for their patients as the dry, cool climate.

SYNCHRONOUS MOTORS IN CENTRAL STATIONS.

BY H. S. KNOWLTON.

The appearance of special machinery in central station practice is always a matter of interest, because it bears evidence of the existence of conditions somewhat out of the ordinary. As a rule the generation of alternating current and its transmission from a central station to moderate-voltage transformers in the business and residential districts of a city calls for nothing but standard apparatus. In the case of a plant which has been operated for a decade or two, however, it is frequently an advantage to employ special equipment to bring the station up to modern standards of flexibility.

An instance of this practice may be found in the Faraday Street station of the Worcester (Mass.) Electric Light Company. The Worcester plant was one of the first electric light stations in New England to be built on a large scale with the probable requirements of later years in mind, and its dynamo equipment, in accordance with the best practice of that day, was all belt-driven from extensive line shafts in the basement below the dynamo room. The arc lighting of the city was done by T-H machines; incandescent circuits were supplied by 133-cycle, 1040-volt alternators, and the few motors in use in printing offices, etc., were served with 500-volt direct current. To-day the line shafting is still in use for driving Brush arc-lighting machines and a 250-kw., three-phase alternator, and the power load is still handled by direct current; but the voltage has been doubled on the incandescent circuits, the frequency reduced to 60 cycles, and 2000 kilowatts in direct-connected alternators installed, with motor-driven oil switches and all the refinements of the latest switchboard practice. As an example of a plant that has been operated with economy and profit while undergoing a partial evolution in equipment, the Worcester station is of particular interest.

The synchronous motor of the plant is a 500-kw. General Electric machine of the revolving-field type. It is mounted upon the line shafting and may be used either as a generator or as a motor. It has a full-load efficiency of 94 per cent and at half load this falls to but 90½ per cent; the voltage of the machine is 2300. The arrangement is exceedingly flexible. In case either the 1200-kw. or the 800-kw. direct-driven alternators of the plant break down, or if their engines go wrong, the motor can soon be operated from the line shafting as a generator to help out the 250-kw. belt-driven alternator. If one or more of the three engines ordinarily used to operate the line shafting breaks down the motor is immediately available for operating the arc and 500-volt power generators. The motor thus constitutes a link between the belt-driven, direct-current machinery of the plant and the engine-driven alternators, and is a safeguard of no small importance in making it possible for the load to be held well up toward normal under adverse conditions. It will be interesting to watch the development of the Worcester station as the evolution of electric lighting proceeds.

An important use of synchronous motors on a large scale occurs in the practice of stations in which it is desirable to drive Brush arc machines by motors instead of by shafting, the main supply of energy coming from engine-driven alternators. Perhaps the most notable illustration of this practice occurs in the L Street station of the Boston Edison Company. Here are installed nearly two dozen arc lighting sets, each consisting of a 150-kw. synchronous motor direct-coupled to two Brush arc dynamos of 8500 volts and 6.6 amperes capacity. The speed of these sets is 514 r.p.m. and the synchronous motors take their current direct from the main 2250-volt bus-bars. The control of the power factor possible with this arrangement is an advantage, and it is unnecessary to use more than one type of alternating-current generator in the lighting and power service of the older section of the plant.

Another instance of synchronous motor practice has recently been mentioned in the technical press. It occurs in an electric light and power plant at Monterey, Cal., where a 162-kw. revolving-field motor is direct-coupled to a 150-kw. direct-current railway generator. At times of light load both machines may be driven as generators by a 200-h.p. engine, which is belted to a clutch pulley mounted on the motor-generator shaft. This arrangement enables both units of the motor-generator set to be run as generators when the load is light, and the railway load may be coupled in with the alternating load at will, giving most efficient operation during the daytime.

It must not be concluded, however, that special equipment of this sort is applicable indiscriminately under all conditions of plant operation. As far as possible it is wise to cut down to a minimum the extra transformations of energy in plants, and it is only when increased flexibility is worth more than the additional losses incurred that it is desirable to insert special equipment in the chain of apparatus between the coal pile and the distributing mains.

AMERICAN WATER-WHEELS AND WATER-WHEEL GOVERNORS

BY LAURENCE B. MATHER.

There are two general types of water wheel in use in America for driving electric generators, the turbine, based on the inverse of the screw propeller principle, and and the impulse or impact type, operated by the direct pressure of a water jet delivered from a nozzle. The turbine is applicable under low and moderately high heads; the impulse wheel is particularly well adapted for operation under very high heads, and has therefore come into wide use in the West where such heads abound.

Turbines are mounted in a variety of ways, the manner of mounting depending largely on local conditions. The simple vertical turbine mounted on the floor of a wooden penstock, as in Fig. 1, is probably the most familiar disposition, and is the easiest and cheapest in installation. It involves the serious disadvantage, however, of using either a special generator of the vertical type and designed for very low speeds, or ponderous gear wheels between the upper end of the turbine shaft and a horizontal shaft from which generators of conventional types may be belt driven. A steel casing and flume are used to a great extent with vertical wheels, however, this arrangement obviating the many disadvantages of wooden structures in wet places; such an arrangement is shown in Figs. 2 and 3. The steel casing is provided with hand-holes and man-holes through which access to the wheel and gate mechanism may be had when necessary.

By far the best method of mounting turbines for electric station purposes, however, is to place two wheels on a single horizontal shaft within a steel casing, the water being delivered to the casing in the center and discharging at both ends through huge elbows to draft tubes, as in Fig. 4. This method equalizes the end thrust, making step bearings unnecessary. It also has the advantage of making the turbine shaft accessible for generator driving without the

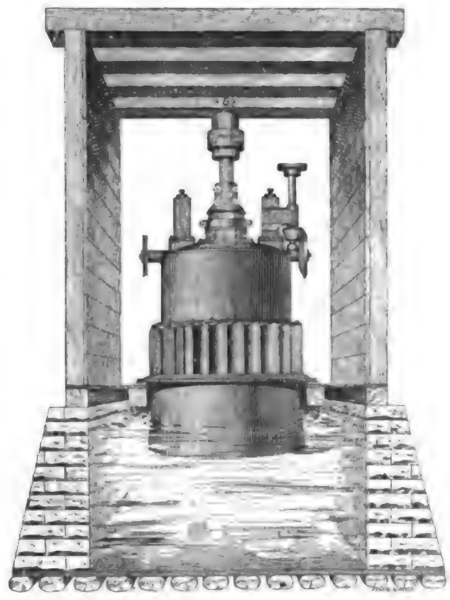

FIG. 1.

intermediary of gears or the use of specially designed generators. Twin horizontal turbines are sometimes mounted in the reverse manner, *i. e.*, with the discharge in the center and the intakes at the ends; this arrangement is not so good as the other, for the reason that the turbine discharge streams meet and each imposes a slight back pressure on the other; the central space cannot be made large enough to prevent this because it must be completely filled with water during the turbine operation in order to enable the wheels to work at maximum efficiency with relation to the supply head.

The delivery of water to a turbine is controlled invariably by means of "gates" in the turbine casing (not the steel casing which takes the place of a wooden penstock, but the immediate casing of the wheel itself). Three general types of gate are in use: the inside cylinder, outside register and the wicket gate. These are described in connection with the turbines in this article, so that a separate description here is not necessary.

One of the oldest American builders of turbines is the Dayton Globe Iron Works Company, Dayton, Ohio, which concern is the development of the business begun in 1853 by Stout, Mills & Temple. The "runner" of the American turbine built by this company is illustrated by Fig. 5. The water enters the wheel in the upper part and imparts motion to it by reason of the fact that the buckets or, more accurately, blades, are curved and the water presses against them like a solid wedge against a sloping surface. Passing through the blades or upper parts of the buckets the water is discharged from the lower parts of the buckets, which are also curved so that the passage of water through them increases the rotative effect of the water upon the wheel. The American wheel is built with either wicket or cylinder gates, as desired. The wicket gate of this wheel is a most ingenious one. Fig. 6 shows the cross-section of the wheel and case and Fig. 7 the top of the wheel-case crown-plate to which the gates are attached. The gates are pivoted to the crown plate and the pivot is shielded by a pocket in the end of a stationary guard or fender, which fender also protects the gate from the inward pressure of the water, making it easy to move. The gates are swung to and fro

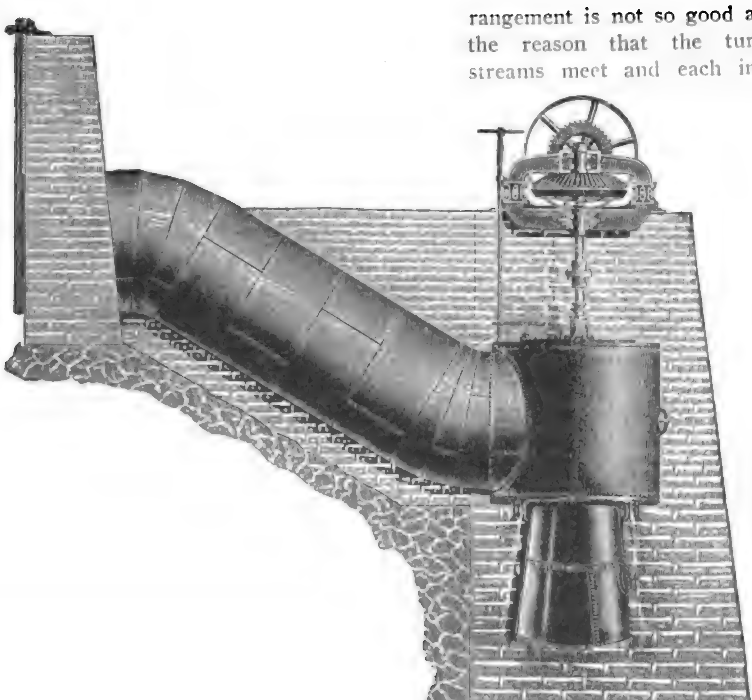

FIG. 2.

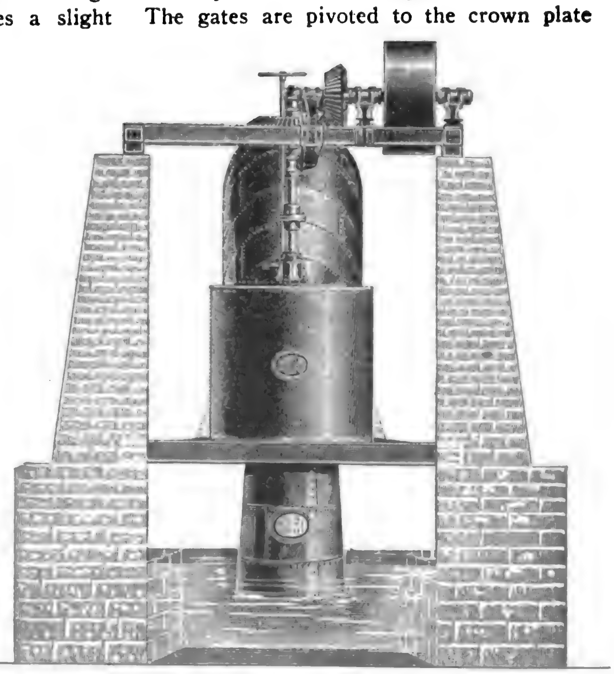

FIG. 3.

by means of links pivotally attached to them near the "knuckles" and attached at their other ends to a ring mounted on the crown plate concentric to the wheel shaft;

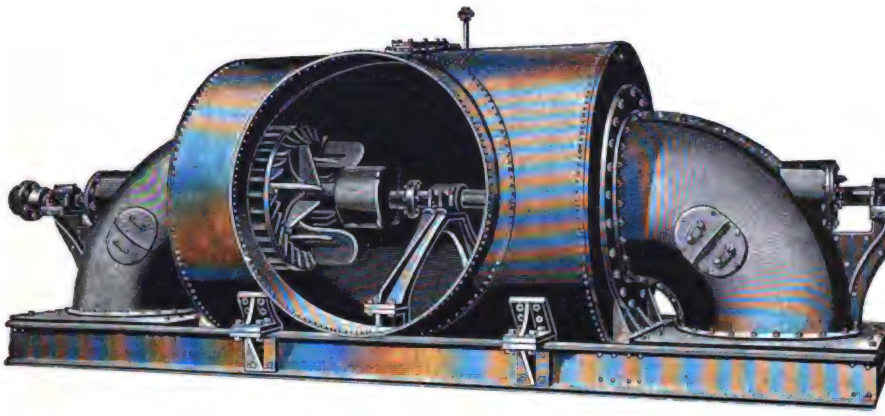

FIG. 4.—TWIN HORIZONTAL TURBINES; CENTRAL INTAKE.

to this ring is bolted a segmental gear and this meshes with a pinion on the end of the

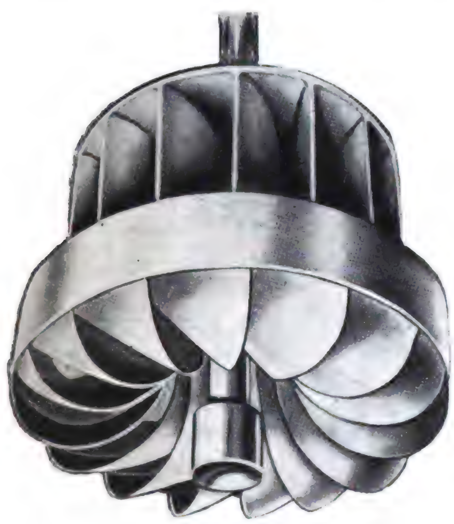

FIG. 5.—RUNNER OF AMERICAN TURBINE.

gate-controlling shaft. The New American cylinder gate is similar to that used on other turbines, one of which is described farther along. The turbine is built in sizes

FIG. 7.—AMERICAN GATE GEAR.

ranging from 13 to 60 inches. The 34-inch wheel, under a 25-foot head, runs at 249 r.p.m. and develops 309 horse-power with a water consumption of 8050 cubic feet per minute. The company also builds a "reduced discharge" wheel for high heads—40 to 100 feet—in sizes ranging from 16½ to 59½ inches; the 36-inch wheel develops 245 horse-power under a 40-foot head, making 226 r.p.m. and taking 4057 cubic feet of water per minute.

Fig. 8 illustrates the turbine built by the Chase Turbine Manufacturing Company, Orange, Mass., and Fig. 9 shows the runner

FIG. 6.—AMERICAN GATE GEAR.

of this turbine. As the engraving plainly shows, the wheel is of the single-bucket type, the water passing through it wholly in a downward direction. This wheel has

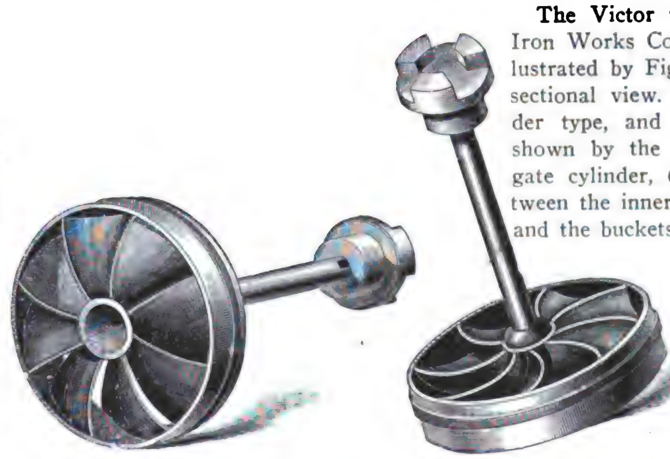

FIG. 9.—RUNNER OF CHASE TURBINE.

the advantage of light weight, high speed and straight flow. The water is admitted at the side of the case through a butterfly gate, as shown by Fig. 8; the case is sufficiently high to allow the water to change its direction of flow from horizontal to downward without undue friction against the walls and without causing eddies. The gate, being pivoted in the center of its vane,

FIG. 8.—CHASE TURBINE.

is balanced and therefore opens and closes easily. The Chase "Special" 48-inch wheel under a 25-foot head develops 292 horse-power at 220 r.p.m. with a water consumption of 8354 cubic feet per minute.

The I-X-L vertical turbine and the X-L-C-R twin horizontal style built by the Humphrey Machine Company, Keene, N. H., are shown by Figs. 10-A and 11. These are of the double bucket type, and have shown rugged characteristics under hard and long service. These wheels are relatively slow-speed; the 68-inch single vertical wheel under a 25-foot head runs at only 88 r.p.m. and develops 265 horse-power with a water consumption of 5614 cubic feet per minute; the twin horizontal wheels run at the same speeds as the verticals of the same diameter and develop twice the power, of course.

The Victor turbine, built by The Platt Iron Works Company, Dayton, Ohio, is illustrated by Fig. 12, of which Fig. 13 is a sectional view. The gate is of the cylinder type, and its arrangement is clearly shown by the sectional illustration. The gate cylinder, *G*, slides up and down between the inner circle of the chute case, *C*, and the buckets of the wheel, *W*. A hori-

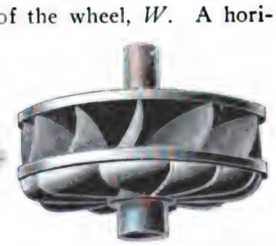

FIG. 10.—HUMPHREY RUNNER.

zontal gate shaft carries two pinions which mesh with two racks attached to vertical slides which are in turn attached at their lower ends to the gate cylinder. The shaft projects through the

wheel case at one end and that end carries a bevel wheel, outside the case, which meshes with a mate wheel on the lower end of the hand-wheel shaft, as shown in Fig. 12. The chute case is a single casting, to which

FIG. 10-A.—HUMPHREY TURBINE.

are bolted the upper and lower parts of the wheel case; the lower part of the wheel case, as will be noted from the engravings, is flared considerably, increasing the area of the discharge and thereby decreasing the velocity of the water in the draft tube as compared with that through the wheel itself. The runner of the regular Victor turbine is shown in Fig. 14, which shows it to be of the double-curve-bucket type. It is cast in a single piece, and the band around the lower ends of the upper bucket blades is turned up true so as to get accurate mechanical balance as well as to reduce the clearance between it and the case to the smallest practical dimension. Fig. 15 shows the Victor high-pressure runner, which differs from the regular runner chiefly in the increase in the central space surrounded by

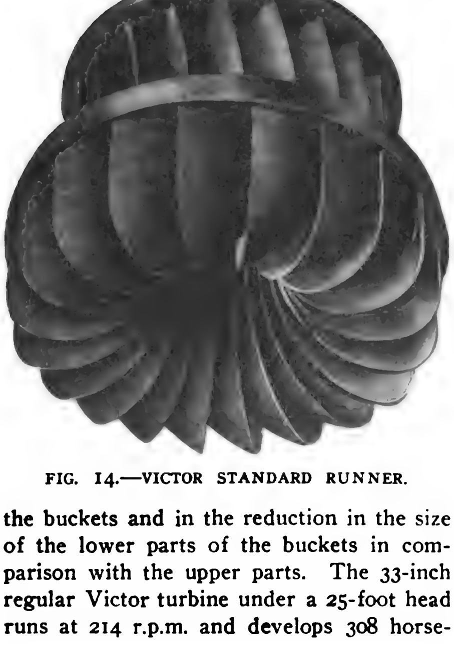

FIG. 14.—VICTOR STANDARD RUNNER.

the buckets and in the reduction in the size of the lower parts of the buckets in comparison with the upper parts. The 33-inch regular Victor turbine under a 25-foot head runs at 214 r.p.m. and develops 308 horse-power with a consumption of 8142 cubic feet of water per minute.

The runner of the McCormick turbine, built by the S. Morgan Smith Company, York, Pa., is shown by Fig. 16. This is

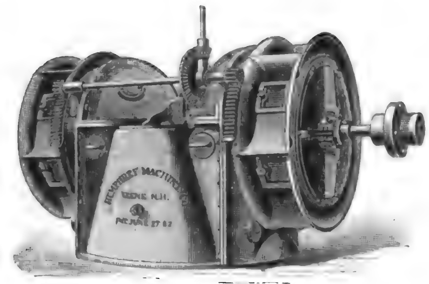

FIG. 11.—TWIN HORIZONTAL HUMPHREY TURBINE.

obviously of the double-curve-bucket type, the water entering the upper parts of the buckets and passing out from the lower parts. The entire wheel is cast solid in one piece, and the band around the change in curvature of the upper and lower parts of the buckets binds fully one-half the length of each of the bottom buckets. The cylinder

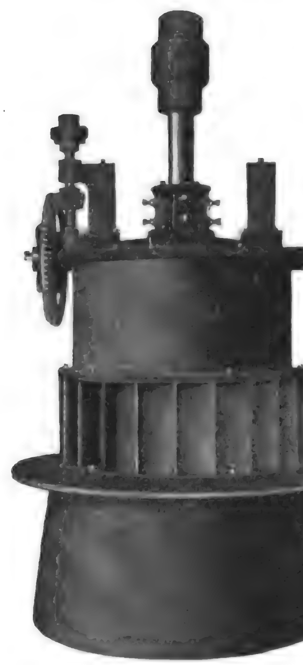

FIG. 12.—VICTOR TURBINE.

type of gate is used, the chute case being cast in one piece and the upper and lower cylindrical parts of the case being bolted to it, as shown in Fig. 17. The gate is a cylinder of iron arranged to slide up and down between the inner ends of the chute blades and the outer rim of the runner, as in the case previously described. The gate has two lifting bars which pass upward through the top of the chute case and terminate in racks, as shown in Fig. 17, the racks meshing with two spur gears on a horizontal shaft and this shaft being controlled by the usual vertical gate shaft through bevel gears. On the horizontal shaft is a grooved wheel about which is wound a chain which passes up over an idler secured to the penstock structure overhead; the end of the chain is attached to a weight which serves to counterbalance the gate, the chain being wound around the grooved wheel on the horizontal gate shaft in the proper direction to accomplish that result, of course. The 36-inch McCormick turbine, under a 25-foot head, runs at 177 r.p.m. and develops 280 horse-power utilizing 7414 cubic feet of water per minute.

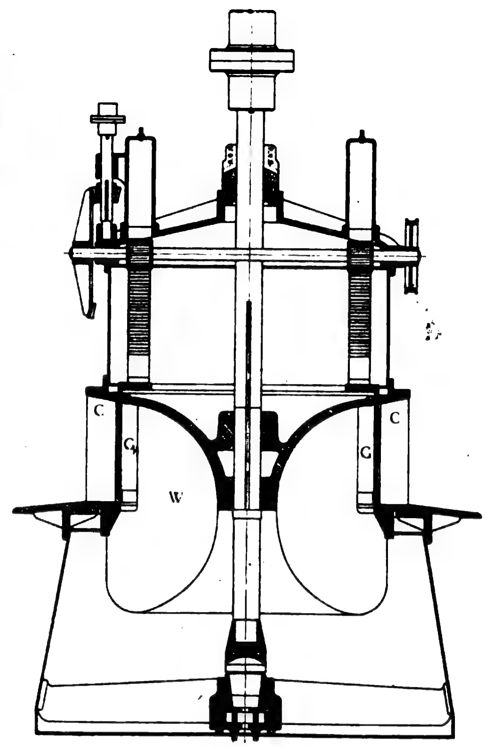

FIG. 13.—SECTIONAL VIEW OF VICTOR TURBINE.

The Alcott turbine, built by the Risdon-Alcott Turbine Company, Mount Holly, N. J., is provided with either register gates or cylinder gates, as desired by the purchaser. The former type is shown in Fig. 18 and the latter in Fig. 19. The outside register gate consists of a system of chute covers attached to a ring, the latter being bolted to arms radiating from a collar on the stuffing box of the wheel case; rotating this structure moves the gates over or away from the chute entrances in much the same fashion that the wings of an ordinary stove damper cover or uncover the openings in the side

FIG. 15.—VICTOR HIGH-PRESSURE RUNNER.

of the stove. The Risdon cylinder gate is similar to those already described, but it embodies detail differences which render it unnecessary to make the wheel case much higher than is actually required to

clear the runner. The gate itself slides up and down through an annular opening in the case, and it is mounted on a spider which slides up and down on the stuffing box of the wheel case. The hub of the

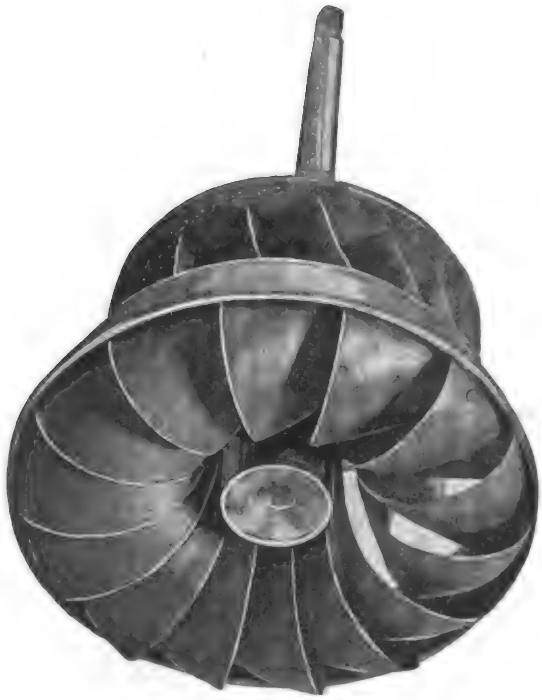

FIG. 16.—RUNNER OF M'CORMICK TURBINE.

spider is provided with a rack to mesh with a pinion on the horizontal shaft, this latter shaft being bevel geared to the vertical gate shaft, as in some of the cases previously considered. The crown plate of the wheel case and the chute case are connected by means of U-shaped arms which straddle the gate cylinder, as shown in Fig. 19. The

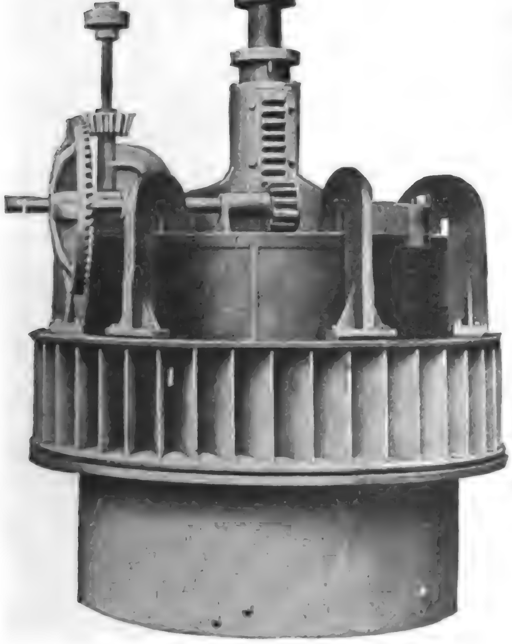

FIG. 19.—RISDON CYLINDER GATE TURBINE.

Alcott "special" runner is shown in Fig. 20; it is of the double bucket type, but it will be noticed that the lower parts of the buckets are somewhat flatter than in previous cases. The outer edges of the upper parts of the buckets, where the water enters the runner, also differ from other designs in that they curve more sharply in the direction of rotation, the object of this construction being to allow the water to enter

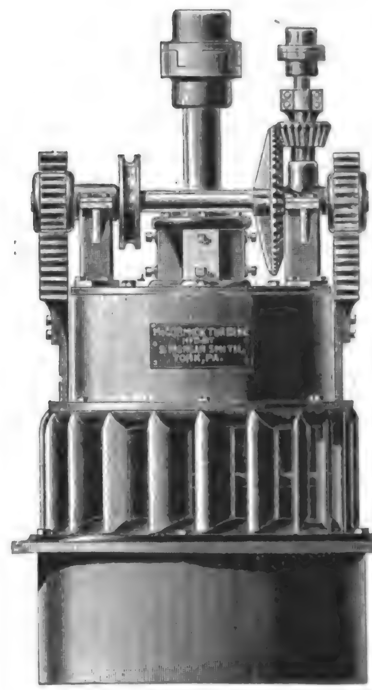

FIG. 17.—M'CORMICK TURBINE.

the buckets easily and without abrupt pressure upon the wheel. The 42-inch Risdon-Alcott "Special" turbine, under a 25-foot head, develops 310 horse-power at 150 r.p.m. and passes 8284 cubic feet of water per minute.

The Samson turbine, built by The James Leffel & Company, Springfield, Ohio, has the distinctive feature of two separate sets of buckets, one of the double-curve type already described, and the other of a type intermediate between the upper and lower parts of the double-curve bucket. The runner of this turbine is illustrated by Fig. 21, in which the two sets of buckets are clearly shown. The upper buckets are cast between

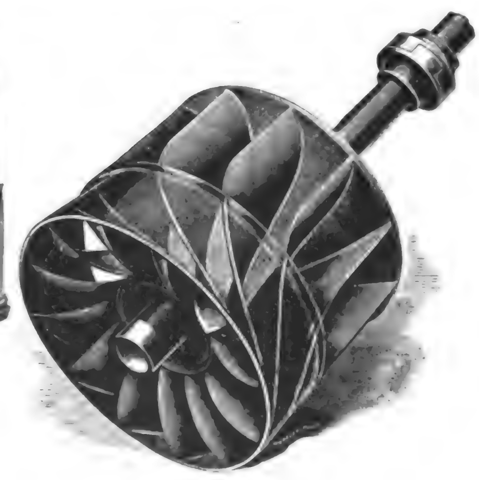

FIG. 20.—ALCOTT SPECIAL RUNNER.

the upper bell of the wheel and the diaphragm which separates these from the lower buckets; the lower buckets, of the double-curve type, are of flanged plate steel cast into the diaphragm and the outer band. The water enters the wheel case through balanced wicket gates and passes through the two sets of buckets "in parallel" so to speak; that is, part of the water goes through the upper set of buckets and part through the lower, double-curve buck-

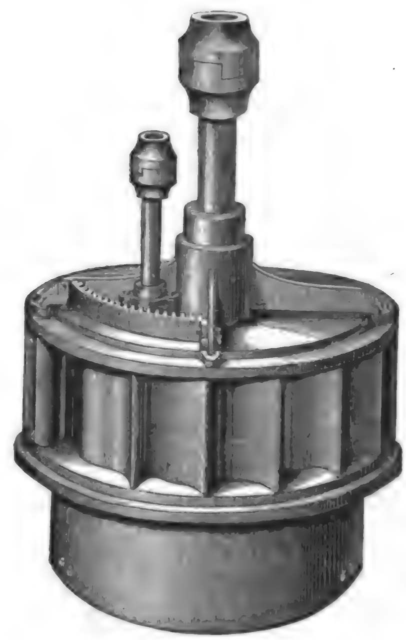

FIG. 18.—ALCOTT TURBINE WITH REGISTER GATES.

ets, the former discharging from the center of the wheel and the latter from the circle of buckets nearer the rim. The 35-inch Samson turbine, under a 25-foot head, passes 8050 cubic feet of water per minute and develops 308 horse-power at 232 r.p.m.

The "Little Giant" turbine, built by William Dowling & Company, Logansport, Ind., is illustrated by Figs. 22 and 22-A. This is of the same general type as the double-curve-bucket turbines already described, but there are differences in the constructional details, such as the curvature of the buck-

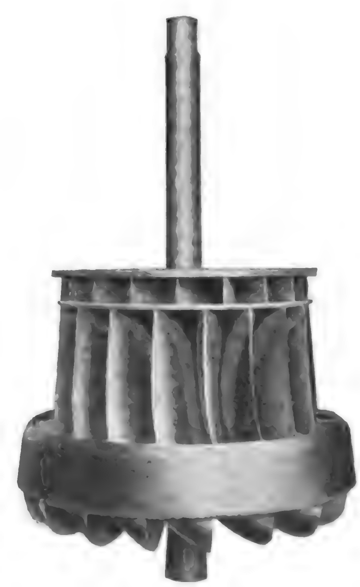

FIG. 21.—SAMSON RUNNER.

ets, which cannot well be described in an article of this general character. Cylinder gates are used, with a horizontal gear shaft projecting through the wheel case at both sides; one end of the shaft is bevel-geared

to the vertical gate-control shaft and the other carries a grooved wheel to take a chain running up over an idler and down to a counterbalancing weight, as in another case described. As Fig. 22-A clearly shows, the gate racks do not pass through the top of the wheel case, but are housed in square "chimneys" bolted to the case. This illus-

FIG. 22.—LITTLE GIANT RUNNER.

tration gives an excellent idea of the relations of cylinder gate turbines with double-curve buckets and the gate cylinder and wheel case. The "Little Giant" runner is constructed somewhat differently from

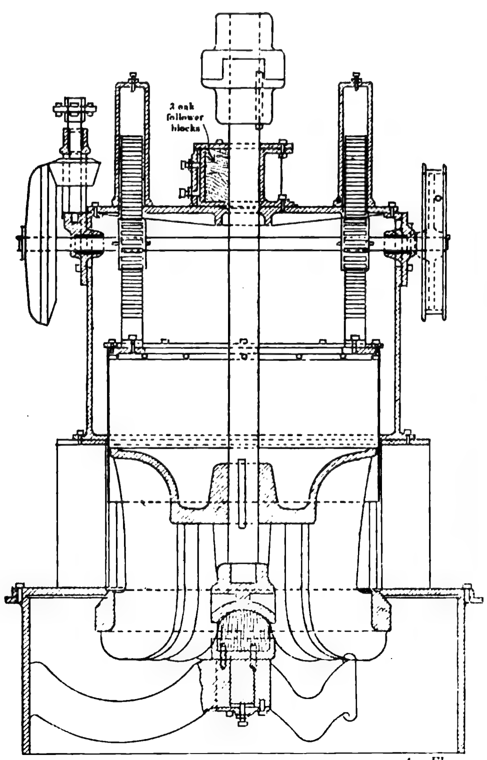

FIG. 22-A.—SECTIONAL VIEW OF LITTLE GIANT TURBINE.

the usual double-curve turbine. The buckets are cast separately, each with a dovetail edge where it joins the bell or cone-shaped central part of the runner and at the outer edge where it joins the band near the bottom of the runner. The buckets are set up in a flask and the outer band and central cone are cast about them, the molten metal embracing the dovetail edges of the buckets as it fills the mold. Another feature of the wheel is the step cone; this is hollowed out, as usual, to fit a convex lignum vitæ step, as shown in Fig. 22-A, but it has openings cored in the sides so as to allow the water to enter the bearing near the top and keep the step lubricated. This simple expedient, the builders state, has absolutely prevented heating and burning of the step. The "Little Giant" is the outcome of the original Obenchain turbine patented 34 years ago by Matthew and John Obenchain, who were then members of the firm which is now William Dowling & Company. The 34-inch turbine under a

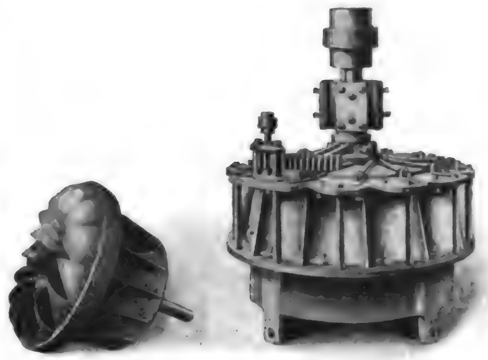

FIG. 23.—TRUMP VERTICAL TURBINE.

25-foot head runs at 200 r.p.m. and develops 285 horse-power with a water consumption of 7434 cubic feet per minute.

The Trump Manufacturing Company, Springfield, Ohio, builds two classes of turbine, both having double-curve buckets; one is for medium and low head and the other especially designed for high heads. The

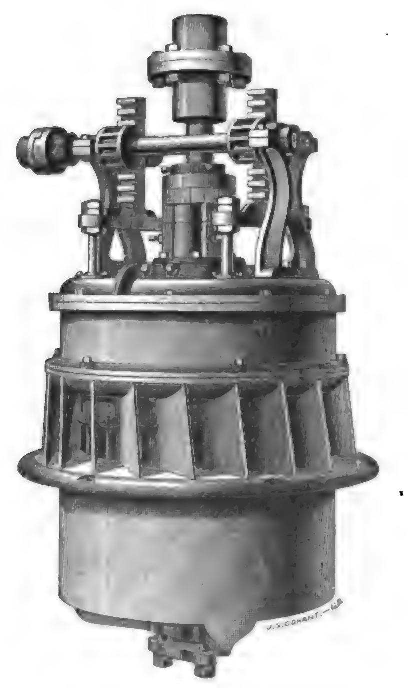

FIG. 25.—HUNT TURBINE; OUTSIDE GATE GEAR.

essential features of the two are the same, with the exception of the gate mechanism which is of the wicket type shown in Figs. 23 and 24 for low and medium heads; the gate mechanism of the high-head turbine is completely housed and devoid of links and joints. The runner of the Trump turbine slopes from the top of the bell to the outer band to the extent of 20 per cent; that is, the diameter is 20 per cent greater at the band than at the top of the bell where the buckets start. An important feature of this turbine is the absence of the usual step bearing. The lower end if the turbine shaft is centered in a tapered bearing as show at *E, E,* Fig. 24; the weight of the wheel is supported, however, by a water

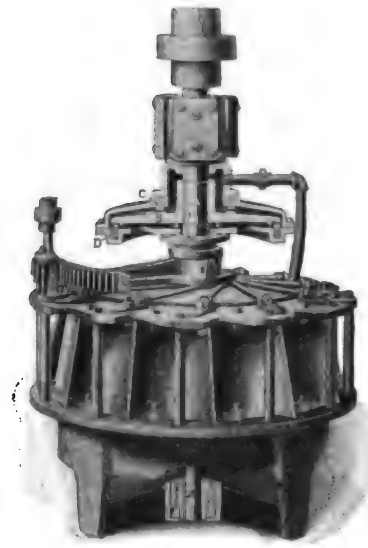

FIG. 24.—TRUMP VERTICAL TURBINE, SHOWING WATER CUSHION.

cushion immediately above the wheel case. This consists of a disc, *B*, secured to the turbine shaft and entirely enclosed by a circular casing, except for holes in the under part through which the water enters from the penstock. The disc rotates between two lignum vitæ rings, *C* and *D*, with such small clearance that the quantity

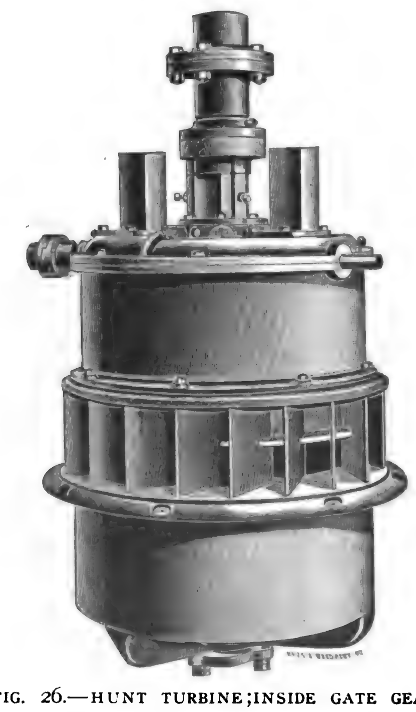

FIG. 26.—HUNT TURBINE; INSIDE GATE GEAR.

of water leaking past the disc is negligible. The upper part of the casing is connected to the wheel case by a small pipe, shown on the right, which takes out all leakage and by means of which the suction due to the passage of water through the turbine maintains a partial vacuum above the disc.

The upward pressure of the water entering through the holes in the bottom of the disc case lifts the turbine runner sufficiently to raise the disc off the ring *D* and float the runner, shaft and all. This water cushion is of great advantage also in turbines mounted horizontally; it eliminates the step

FIG. 27.—CROCKER TURBINE RUNNER.

bearing without making it necessary to mount two wheels on a single shaft.

The Rodney Hunt Machine Company, Orange, Mass., builds turbines with double-curve buckets also. The author has been unfortunately unable to obtain any information as to the constructional details of the runner; the gate rig is shown by Figs. 25 and 26. Cylinder gates are used, the only difference between the two arrangements illustrated being in the disposition of the gate racks and pinions. In Fig. 25 the racks and pinions are on top of the wheel case and the racks are attached to the gate by means of rods passing through stuffing boxes in the top of the case; in Fig. 26 the entire rigging is enclosed in the wheel case, the racks being housed by "chimneys" and the gate shaft projecting through the sides of the wheel case. The 42-inch Hunt tur-

FIG. 31.—PELTON RUNNER.

bine under a 25-foot head develops 302 horse-power at 150 r.p.m. and passes 7720 cubic feet of water per minute.

The Crocker turbine, built by the Turners Falls Machine Company, Turners Falls, Mass., has double-curve buckets also, and is equipped with either balanced cylinder gates or wicket gates. The buckets are cast separately and set into the body and outer band; inspection of Fig. 27 will show that the band flares outward at an angle of almost 45 degrees, giving a rapidly increasing discharge area. Another feature peculiar to this turbine is that the upper parts of the buckets are reverse-curved, the slope from top toward the bottom being in the direction of rotation. The 30-inch wheel runs at 244 r.p.m. under a 25-foot head, takes 6680 cubic feet of water per

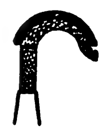

FIG. 28.

FIG. 29.

minute and develops 253 horse-power; the 36-inch wheel runs at 203 r.p.m., takes 10,350 cubic feet of water and develops 380 horse-power.

Tangential water wheels are built by several manufacturers, all of whom are located on the Pacific coast, this type of wheel being best adapted for the very high heads which are found in the Western part of this country. The tangential wheel consists essentially of a spider or disc mounted on a shaft and carrying around its rim a row of concave buckets; a stream of water is delivered to the buckets from a nozzle, and the force of the jet acting on the buckets drives the wheel around in somewhat the same manner as the weight of the water delivered to the paddles of an

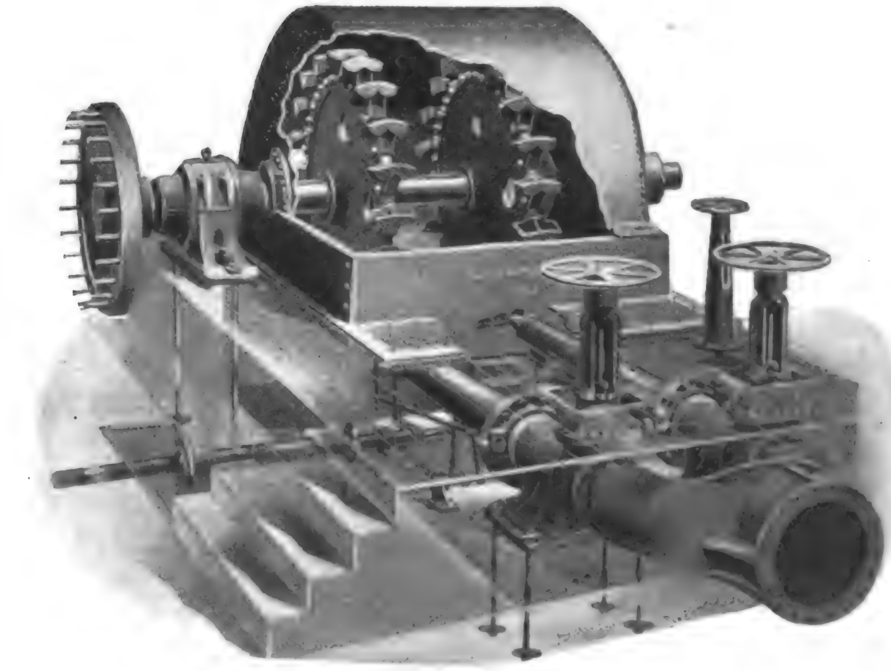

FIG. 32.—PELTON UNIT IN TELLURIDE POWER HOUSE.

overshot wheel turns the wheel. There is a wide difference, however, in the fundamental principles of the tangential wheel and the old-fashioned overshot wheel; the latter is driven solely by the weight of the water held in its buckets while the tangential wheel is driven by a combination of the direct force of the high-pressure jet delivered against its buckets and the reaction of the water upon the buckets after it has reached them. This reactive effect is obtained by curving the buckets so that the water jet is completely reversed in direction, as indicated in Fig. 28. Since the reaction of the jet on the bucket due to its change in direction is less than the initial effort due to the impact of the jet, a jet delivered as indicated in Fig. 28 would exert a sidewise effort on the bucket; this is obviated in most tangential wheels by the use of a split bucket, as indicated in Fig. 29, which divides the jet and equalizes the side thrust.

FIG. 30.

Three general types of bucket are used: the straight lip bucket with substantially rectangular outline, the ellipsoidal bucket with the lip cut away to clear the jet, and the cup-shaped bucket, intermediate between the first two. The straight lip bucket is used by the Pelton Water Wheel Company; Fig. 30 shows this type and Fig. 31 shows a complete Pelton runner. Fig. 32 is an illustration of the 2000-hp. Pelton double unit in the celebrated Telluride (Colorado) transmission plant, and shows very well the method of mounting tangential wheels and their nozzles. The methods used by the Pelton Company, of San Francisco, in determining the action of the water stream upon the wheel buckets were fully described in the June, 1904, number of this journal, and will be found of much interest to those concerned.

The Abner Doble Company, San Fran-

cisco, builds tangential wheels with ellipsoidal buckets, Fig. 33 showing a twin bucket and Fig. 34 a complete Doble runner. The nozzle used with the Doble wheel is highly interesting. It is of the needle-regulating type, but the shape of the needle and the inner wall of the nozzle have been very carefully worked out. These are clearly shown in Fig. 35. The stream delivered by this nozzle is perfectly clear, smooth and solid; entirely devoid of the spraying and foamy appearance of a stream from the ordinary nozzle. Speed regulation for changes in load is effected by means of a governor which deflects the nozzle and "spills" part of the jet when the speed increases; the needle is adjusted by hand to suit the average load; that is to say, it is adjusted to such a position that the governor will not need to deflect the nozzle under average conditions and the buckets will receive the full jet under such conditions. The front lip of the bucket is cut away as shown in Fig. 33 in order to prevent the lip from striking the jet flatwise as the bucket enters the jet and also to prevent splitting the jet horizontally as the lip passes the horizontal plane of the jet. It is stated that this form of lip and bucket avoids all disturbance of the jet and accomplishes the reversal of the jet with no loss of energy except that due to the unavoidable friction of the water against the bucket walls.

FIG. 33.—DOBLE TWIN BUCKET.

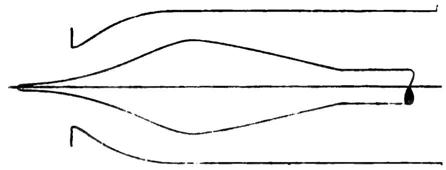

FIG. 35.—DOBLE NOZZLE.

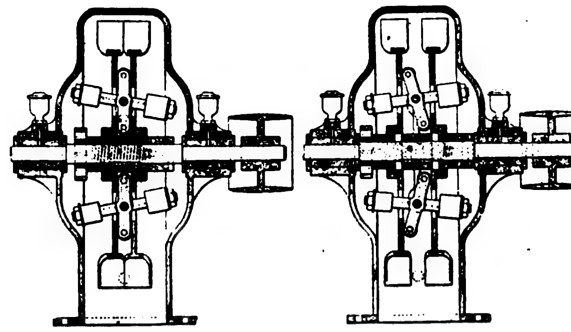

FIG. 37.—CROSS-SECTIONAL VIEWS OF CASSEL WHEEL.

The Cassel Automatic Water Motor Company, Seattle, Wash.; builds a tangential wheel which embodies a speed-regulating feature of absolute originality. The wheel is made in two parts, each carrying a complete set of half-buckets, as shown in Fig. 36. The two spiders are mounted on a common shaft and arranged to slide along the shaft, their relative positions being determined by means of governor weights. This principle is illustrated by Fig. 37, which shows the wheel with the buckets closed and open. In the former condition, it acts like an ordinary twin bucket wheel but in the latter, the separation of the bucket halves allows part of the stream to pass between them and thereby reduces the speed of the runner. The spiders are normally pressed together by the heavy coil springs shown in Fig. 36; their separation is due to the centrifugal effect of the heavier of two sets of weights mounted on horizontal arms which are linked to the spiders by means of cross-bars. Fig. 38 shows a modification in which the governor is of the familiar type seen on automatic high-speed steam engines; the weights and springs control the positions of the bucket spiders in the casing through the medium of links and a collar passing through the case near the center. The builders state that tests of this wheel under a 1000-foot head have shown a speed variation of only 1.7 per cent between no load and full load.

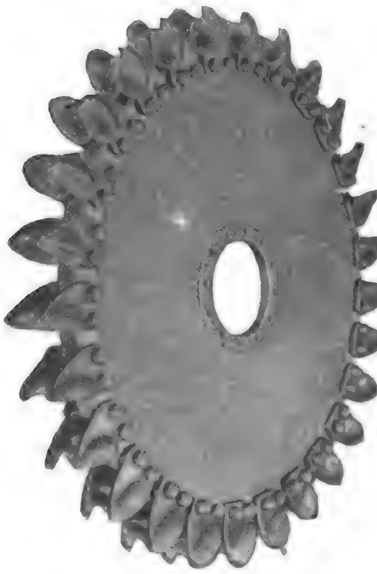

FIG. 34.—DOBLE RUNNER.

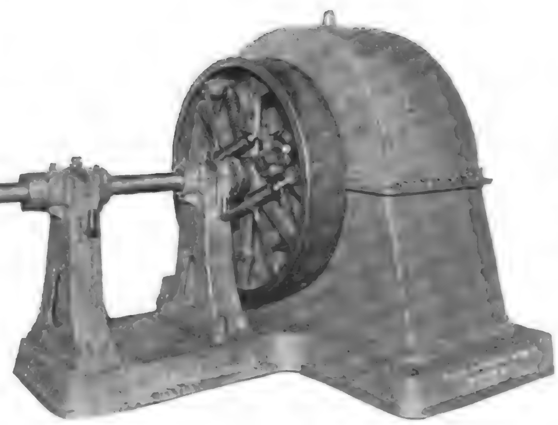

FIG. 38.—CASSEL TANGENTIAL WHEEL.

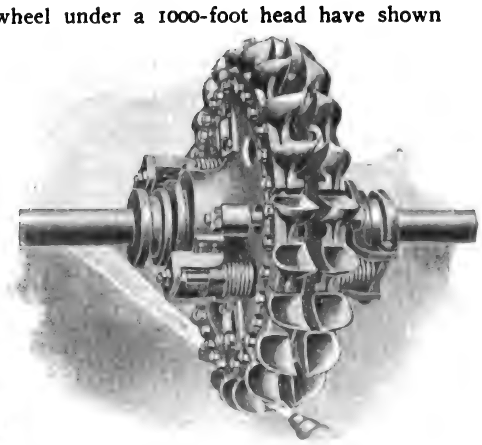

FIG. 36.—RUNNER OF THE CASSEL TANGENTIAL WHEEL.

The tangential wheel, built by the Joshua Hendy Machine Works, San Francisco, is illustrated by Fig. 39. The buckets are of the double-cup type referred to at the beginning of this section of the article. Fig. 40 illustrates the Chavanne needle-regulat-

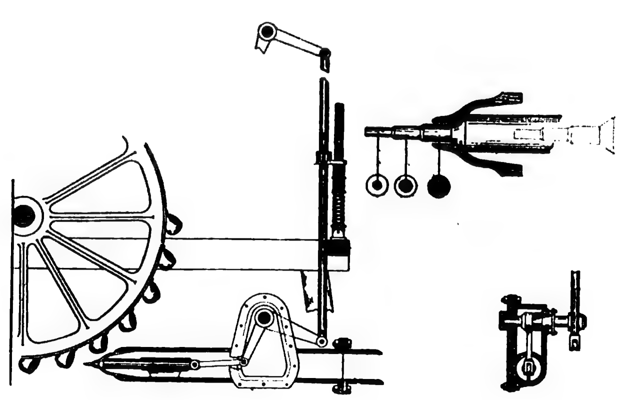

FIG. 40.—CHAVANNE NEEDLE REGULATING NOZZLE OF THE HENDY WHEEL

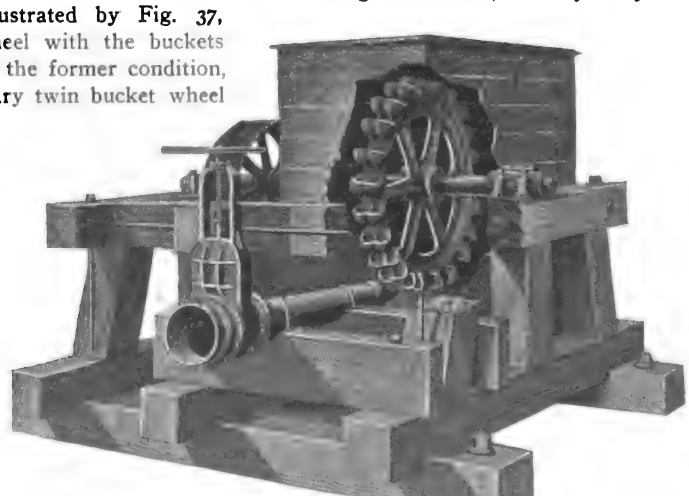

FIG. 39.—HENDRY TANGENTIAL WHEEL.

ing nozzle used with the Hendy wheel; the jet is regulated by the adjustment of the needle which is not made continuously tapering, as in some other nozzles, but has three distinct diameters, as shown in the upper right-hand part of the engraving.

FIG. 41.—TUTTHILL RUNNER.

The Tutthill tangential wheel, built by the United Iron Works, of San Francisco, differs from all of the wheels previously described in that the buckets are not of the split type and are staggered on the rim of the wheel, as shown in Fig. 41. Each bucket takes the entire stream from the nozzle, but the discharge from the buckets is alternately on the right and left of the central spider, as indicated by Fig. 42. One object in staggering the buckets instead of having all of them on one side of the wheel is the same as that in using the divided bucket of the Pelton and other wheels, namely, to avoid unbalanced side stress on the wheel, which would necessitate a step bearing or thrust at one end of the shaft. Another reason for this arrangement of buckets is that the discharge being alternately from opposite sides of the wheel, the water from one bucket does not strike the next succeeding bucket and cause waste of power.

FIG. 42.

Water-wheel Governors.

Figs. 43 and 44 illustrate the "Improved" governor built by the Holyoke Machine Company, Worcester, Mass. The pulley *A* is driven at about 400 r.p.m. by a belt from the water-wheel shaft; the governor mechanism in the pulley, which is similar to the shaft-type of governor for steam engines, controls the two levers, *K* and *L*, which actuate a piston slide valve within the barrel *N*. This valve admits water under pressure to either one end or the other of the working cylinder *O* which contains a piston; the piston rod is attached at its outer end to the upper end of the lever *G*, Fig. 43, which carries in the circular part at its center a pivoted nut *V*. This nut is threaded on the end of a rod *F* which, when moved endwise, sets one of two friction clutch discs, *D, D*, which are driven in opposite directions by gears from the shaft of the governor wheel *A*. One of the clutches, therefore, drives the gate shaft (*J*, Fig. 44) in one direction and the other drives it in the opposite direction, through the gears *R* and *S*. The spindle *F*, Fig. 43, carries a sprocket wheel over which the chain *H* runs, and this chain also runs over a sprocket on a small spindle driven by whichever clutch disc is made active by the governor wheel. When the governor admits water to the working cylinder, the piston sets one of the disc clutches by moving the lever *G*; the spindle driving the chain *H* is then driven by the clutch in such a direction that the rotation of the spindle *F* by the chain and sprocket moves the lever *G* in the opposite direction from that in which it was first moved by the water piston. This arrangement prevents overrunning and "hunting."

The governors made by the Lombard Governor Company, of Boston, Mass., consist primarily of a hydraulic piston which applies its thrust in either direction to the water-wheel gates in the act of opening or closing them. The piston rod terminates in a rack geared to the gate shaft, and since one complete stroke of the governor piston opens or closes the water-wheel gates, any motion of the governor piston less than a complete stroke causes a correspondingly smaller motion of the gates. For example, if the governor piston moves one-half its complete travel it will half open or close the water-wheel gates, and if it moves one-tenth its full stroke it opens or closes the gates one-tenth. This action may be seen in a general way from Fig. 45, which illustrates the "Type F" governor. This governor, which is the simplest and smallest made by them, is adapted to regulating Pelton and all other forms of impulse or tangential water-wheels. Its piston terminates in a rack which rotates a gear sector, and the central shaft of this sector is coupled or geared to the rock shaft controlling the deflecting nozzle. When used to regulate a small turbine, the central shaft of the gear sector is coupled to the gate stem. Thus it will be seen that as the piston travels in or out the nozzle will deflect the water from or to the water-wheel, or open or close the gates of the turbine, as the case may be. In the governor shown in Fig. 45 the hydraulic piston is moved by water under flume pressure. There is a pipe-threaded orifice under the bed of this governor which is connected directly to the flume. Therefore this type of governor is chiefly adapted to high head plants, or to low head plants where a small amount of water is available under high pressure. Where the water-

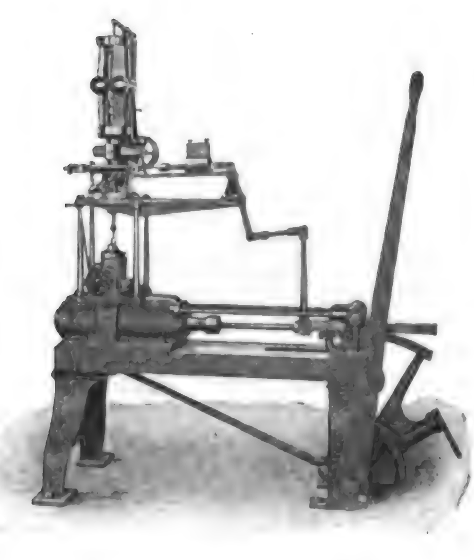

FIG. 45.—"TYPE F" LOMBARD GOVERNOR.

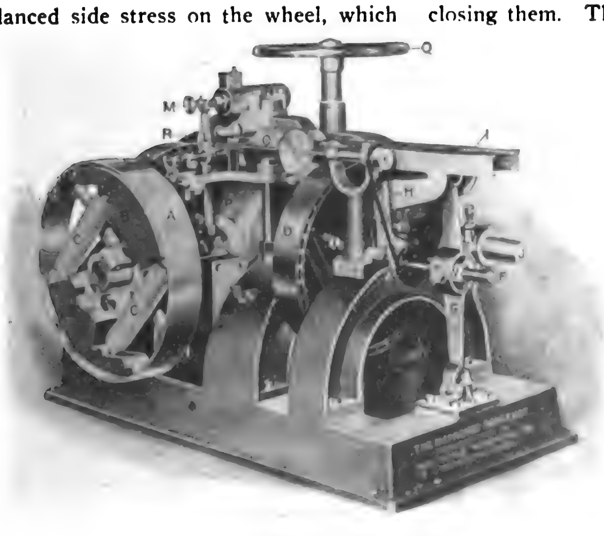

FIG. 43.—"IMPROVED" GOVERNOR.

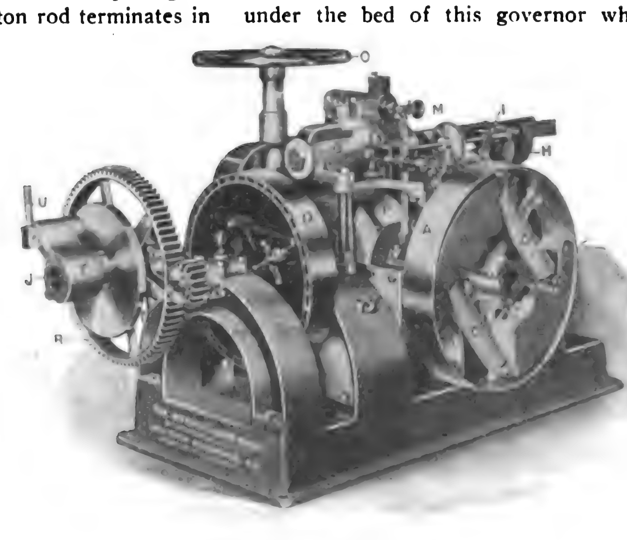

FIG. 44.—"IMPROVED" GOVERNOR.

wheels operate under low head, or where there is no water available under high pressure, a type of governor is used in which the piston is moved by oil under pressure.

Fig. 46 shows the "Type D" governor, which operates with oil under pressure. It

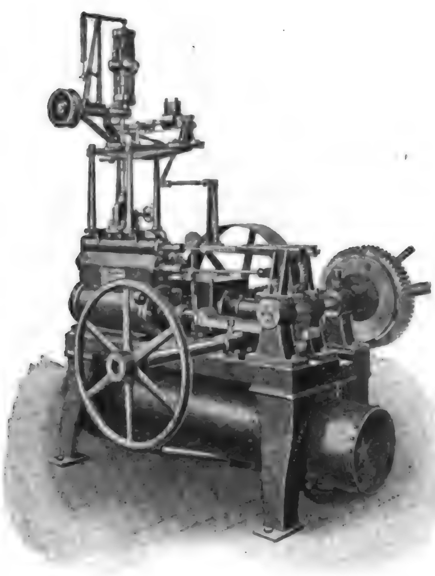

FIG. 46.—"TYPE D" LOMBARD GOVERNOR.

will be observed that under the bed of the governor is a cylindrical tank. This is divided into two parts by a tight partition, the location of which may be seen from the row of rivet heads. The larger part of the tank shown to the left in Fig. 46 is about half full of oil. The upper half of this pressure tank contains air under about 200 pounds pressure to the square inch. The smaller end of the tank shown to the right in Fig. 46 contains a vacuum. The pressure and vacuum are said to be constantly maintained by a pump located on the farther side of the bed of the governor and driven by the larger pulley shown, which is belted so as to slowly rotate all the time the governor is in operation. When the governor piston moves the water-wheel gates it is because oil from the pressure tank is let in on one side of the

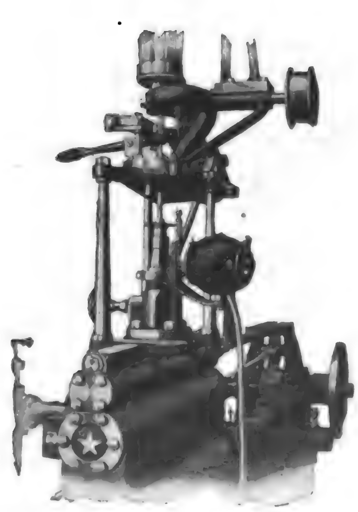

FIG. 47.—MECHANISM ON TOP OF GOVERNOR.

piston; simultaneously the oil on the other side of the piston is vented into the vacuum tank, whence it is immediately pumped into the pressure tank. Fig. 47 shows the mechanism on the top of one of the governors; through which the governor is made to open or close the water-wheel gates when the speed tends to change. All of the governors are fitted with practically the same top, the action of which is as follows: The pulley shown in Fig. 46 is belted directly to the water-wheel shaft and drives the governor balls which, when rotating at normal speed, stand out considerably from the axis of rotation. The mechanism is such that as the balls spread out under the action of centrifugal force they depress the top plate

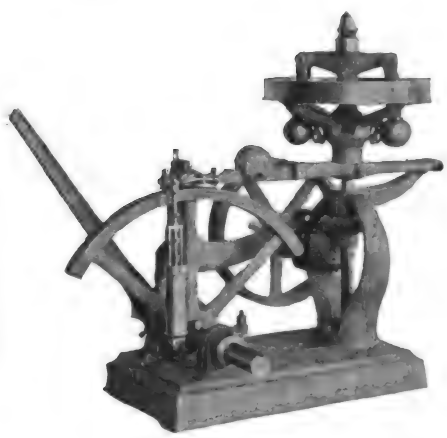

FIG. 48.—REPLOGLE GOVERNOR.

into which the flat springs supporting them are inserted. This top plate is attached to a rod which passes down through the hollow vertical shaft carrying the balls, and terminates in a small vertical piston valve located behind the hand-wheel shown near the bottom of the illustration. It will be evident therefore that as the balls fly out under the influence of increased speed they will depress the piston valve, and, conversely, as they travel inward when the speed becomes below normal, they will lift it. The valve stem or rod referred to is of such length that when the balls are in the position due to normal speed the valve is closed; but the moment the speed becomes above or below normal the piston valve is said to admit oil or water, to one side or the other of the main piston of the governor,

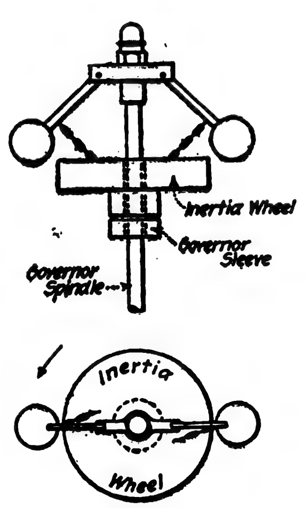

FIG. 49.

causing it to open or close the water-wheel gates. As the rotating balls are claimed to be exceedingly sensitive and as the piston valve has a very small lap, the least change in speed of the water-wheel is said to cause the governor to open or close the water-wheel gates.

There are several types of Replogle governor (built by The Replogle Governor Works, Akron, Ohio), of which three are illustrated by Figs. 48 to 52 inclusive. Fig. 48 shows the simplest form of governor, in which the governor balls raise and lower the horizontal arm pivoted to the extension at the right of the frame. The free end

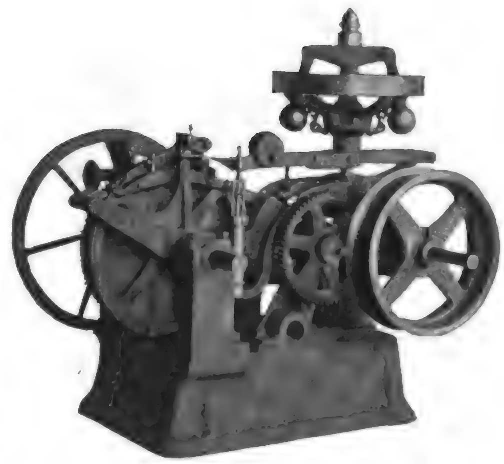

FIG. 50.—REPLOGLE "DUPLEX" GOVERNOR.

of this arm carries a spring finger which swings a double-ended pawl to and fro; one end of the pawl, when depressed, engages one set of ratchet teeth on the segment keyed to the gate shaft, and the other end engages the reverse set of ratchet teeth on the same segment. The double pawl is pivoted to the upper end of a lever which is continuously oscillated by a cam on the governor pulley shaft. When the governor arm is lifted, the left-hand end of the pawl engages its ratchet and moves the segment, step by step, to the left, closing the water-wheel gate, or deflecting the nozzle, as the case may be. Contrary mo-

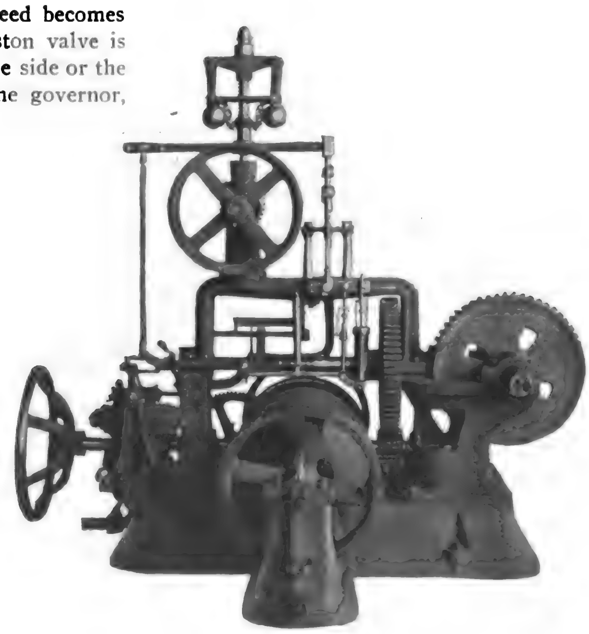

FIG. 51.—REPLOGLE DIFFERENTIAL GOVERNOR.

tion of the governor arm produces the contrary result, of course. An interesting feature of this governor is the arrangement of the governor balls and an inertia wheel which surrounds the ball arms. Instead of

being rigidly linked to the sliding collar on the governor spindle, the ball arms are connected by short chains to the inertia wheel; this wheel is entirely loose on the governor spindle and its hub forms the sliding collar which raises and lowers the horizontal arm; this arrangement is shown diagrammatically in Fig. 49. Should a sudden increase in speed occur, the governor balls will be thrown outward, of course, raising the inertia wheel and its collar, but this action is not instantaneous and it is anticipated by the action of the inertia wheel. When the speed changes, the wheel lags behind the governor spindle momentarily and thereby increases the slant of the chains connecting it with the ball arms; the result is the raising of the inertia wheel and checking of the turbine speed before the centrifugal force of the governor balls has acted to and overcome their inertia.

In the "Duplex" Replogle governor, Fig. 50, the governor balls control a double-ended pawl, as in the preceding type, but this pawl instead of operating the gate shaft, shifts a pivoted cam back and forth; this cam when moved over to one end of its travel raises one of the gate-operating pawls out of reach of the segmental ratchet on the gate shaft; when moved in the opposite direction, it releases the pawl just mentioned and lifts the opposite pawl away from its ratchet; in the middle position, both pawls are lifted away from the ratchets on the segment. The gate-operating pawls are pivoted to a lever which is oscillated from the governor pulley shaft. This governor is adapted for heavier work than the one first described.

The differential governor shown by Fig. 51 is designed for use with large power units and is capable of exerting 15 horse-power on the gate shaft. This embodies the inertia feature already described but in modified form. The governor balls raise or lower the usual form of sliding collar by chains, and the collar, through a system of links and levers, shifts a spherical clutch axially so as to contact with one or the

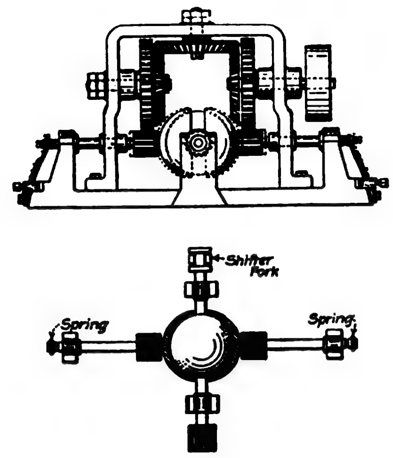

FIG. 52.—CLUTCH OF REPLOGLE GOVERNOR.

other opposite edges of friction cups surrounding the ball and driven by gears from the main shaft. This arrangement of the clutch is shown conventionally by Fig. 52. The hemispherical cups are mounted on short shafts which are driven in opposite directions and are also pressed toward the clutch sphere by springs at each end. The governor mechanism shifts the sphere axially by means of the pawl and ratchet mechanism on the left of the illustration; when the sphere is at one extreme of its axial travel, it is driven in one direction by the two cups; at the other end of its travel it is driven in the opposite direction; at all intermediate positions except the exactly central one, it is driven at speeds which become slower as it approaches the center of its axial travel, and it comes to a standstill at the center. The shaft on which the clutch ball is keyed is geared to the gate-shaft through the spur and bevel gears shown on the right in Fig. 51. All of the Replogle governors are equipped with a compensating device, termed by the builders a "relay releasing cylinder," which cuts the governor out of action after a predetermined period of operation and prevents over-running and hunting. The company also builds a type of governor intermediate between the "Duplex" and the differential types shown in Figs. 50 and 51.

Fig. 53 illustrates the Woodward compensating type of water-wheel governor, built by the Woodward Governor Company, Rockford, Ill. A double friction clutch is also used in this governor, but it is of the bevel type similar to that used in some friction-clutch pulleys. The power shaft of the governor is driven by belt and from it the governor spindle is belt-driven. The power shaft carries a double-coned friction wheel made of compressed paper; on each side of this wheel is a cup-shaped friction wheel mounted loosely on the shaft and carrying a pinion at its center. The friction cups or "pans," as they are termed, are prevented by collars from axial motion and the power shaft is moved axially by the controlling mechanism so as to put the friction wheel into contact with one of the embracing "pans" or out of contact with both, according to the requirements. The friction "pans" are geared to the gate shaft oppositely, so that one of them closes the gate and the other opens it. Fig. 54 shows the controlling mechanism. The horizontal disc at the left of the picture is driven continuously by spiral gears and a belt from the

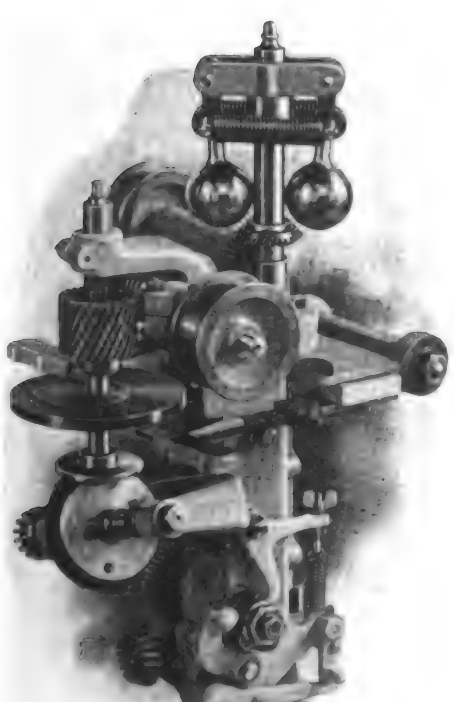

FIG. 54.—WOODWARD CONTROLLING MECHANISM.

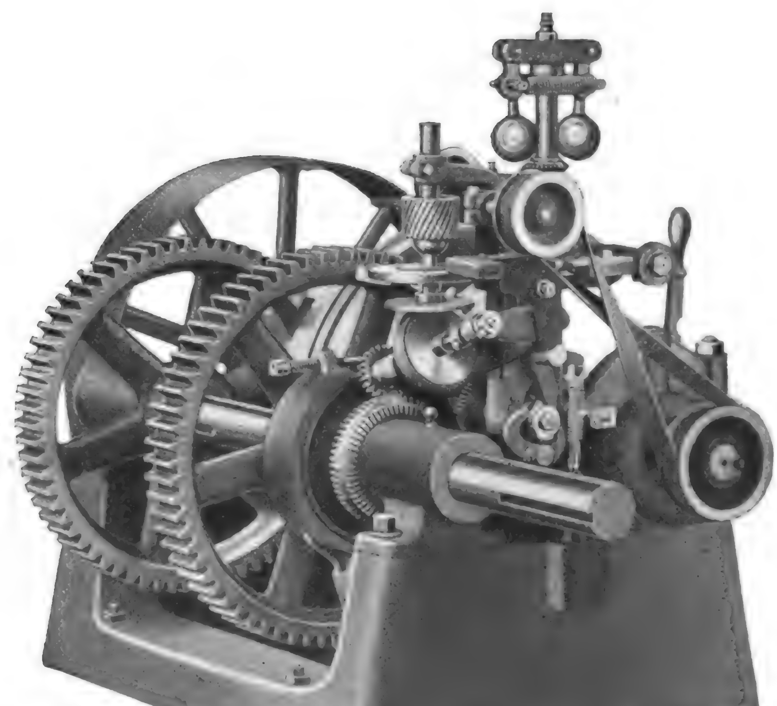

FIG. 53.—WOODWARD WATER-WHEEL GOVERNOR.

power shaft; this disc has a cam on the upper face and one on the under face. The governor balls merely put one of two fingers into engagement with the corresponding cam on the horizontal disc; these fingers are actuated by their respective cams, one

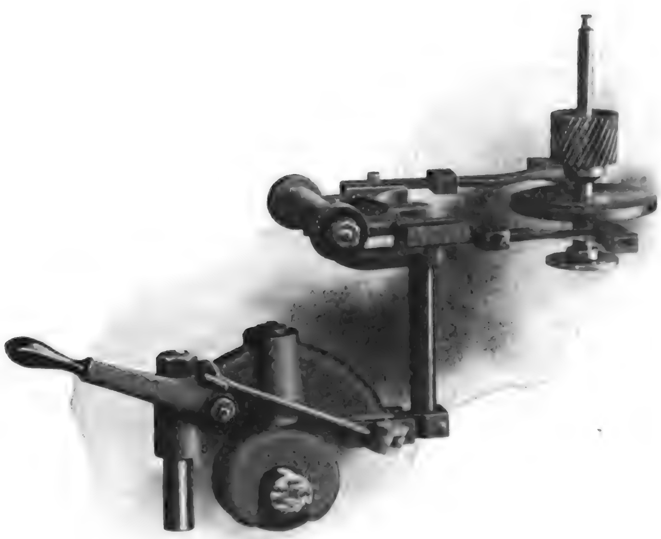

FIG. 55.—DETAIL OF WOODWARD CONTROLLING MECHANISM.

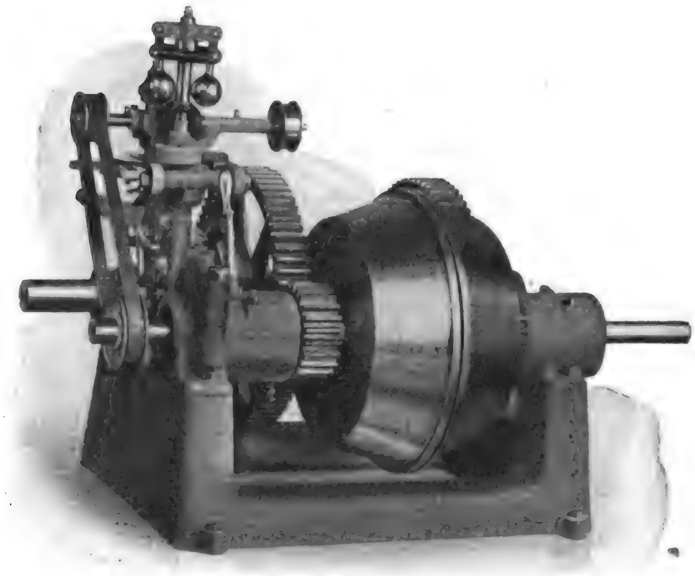

FIG. 56.—WOODWARD WATER-WHEEL GOVERNOR; REAR VIEW.

to force the power shaft in one direction (axially) and clutch one of the friction "pans" and the other to produce the contrary results. On the same spindle with the horizontal cam disc is mounted a friction disc which rests upon the edge of a friction wheel journaled in a yoke set diagonally; this is clearly shown in both illustrations. The hub of the latter wheel is threaded to fit loosely a screw-thread on the diagonal spindle; this spindle is driven by gears from the gate shaft, so that it rotates one way when the gate is being closed and the other way when the gate is opening. The normal position of the tilted friction disc is at the center of the horizontal disc; if, for example, the governor balls set the upper cam finger against the cam and start the gate shaft in whichever direction this action produces, the diagonal spindle geared to the gate shaft will be revolved in such a direction as to draw the tilted friction wheel downward along its screw, lowering the horizontal friction disc and thereby taking the cam disc out of reach of the upper cam finger and releasing the friction "pan" driving the gate shaft. The threaded spindle comes to a stop; of course, with the gate shaft, and the tilted disc is then run back on the stationary threaded spindle to the center of the horizontal disc by the continuous rotation of the latter. This compensating arrangement is to prevent overrunning and hunting.

The governor built by the Sturgess Governor Engineering Company, West Troy, N. Y., is of the hydraulic type, *i. e.*, the wheel gate is operated by hydraulic pressure instead of by power derived from the turbine itself. Instead of using a cylinder and piston of the ordinary type, however, an arrangement based on the general principle of the rotary engine is employed, in which, however, the rotary part makes only 0.87 of a revolution. Fig. 57 shows this governor. On the gate shaft is mounted a rotary piston which is enclosed in a cylindrical chamber; this chamber constitutes the lower part of the machine. Immediately above this chamber are the valve chest and valves controlling the motion of the rotary piston. The main valve is of heavy, substantial construction and is operated hydraulically, its motion being controlled by a pilot valve mounted in the center of it and adapted to open ports in the main valve, as indicated in the sectional view, Fig. 58. The pilot valve is actuated by a centrifugal governor of the ordinary shaft type, which revolves loosely on an extension of the rotary piston shaft and is belt-driven through the medium of the expansible pulley shown on the extreme right, the power for driving being derived from the main turbine shaft.

On top of the valve chest is mounted a dash-pot, which is adapted to slide on its seat in a direction parallel with the motion of the main valve. The tendency of this dash-pot is to remain in the center of its travel, as indicated in Fig. 58, irrespective of the position of the piston within. Upon variation of the load the centrifugal governor operates the pilot valve in the proper direction to effect the further opening or partial closing of the turbine gate, according to the necessity of the case. As soon as the gate shaft begins to move, the cam near

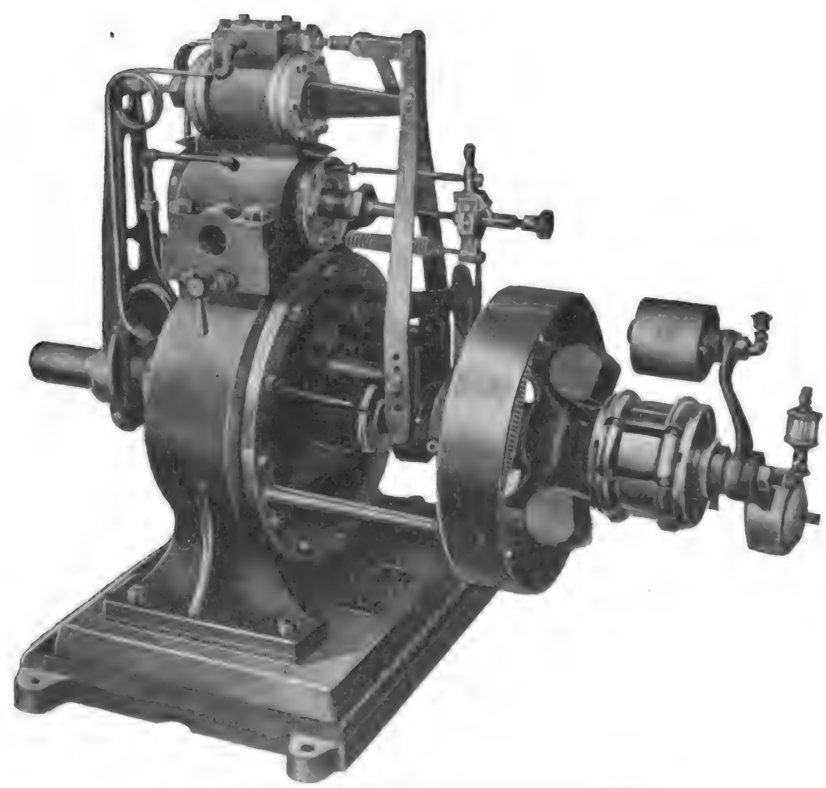

FIG. 57.—STURGESS WATER-WHEEL GOVERNOR.

the left-hand end of that shaft operates the vertical lever, which in turn forces the piston of the dash-pot in one direction or the other, according to the direction in which

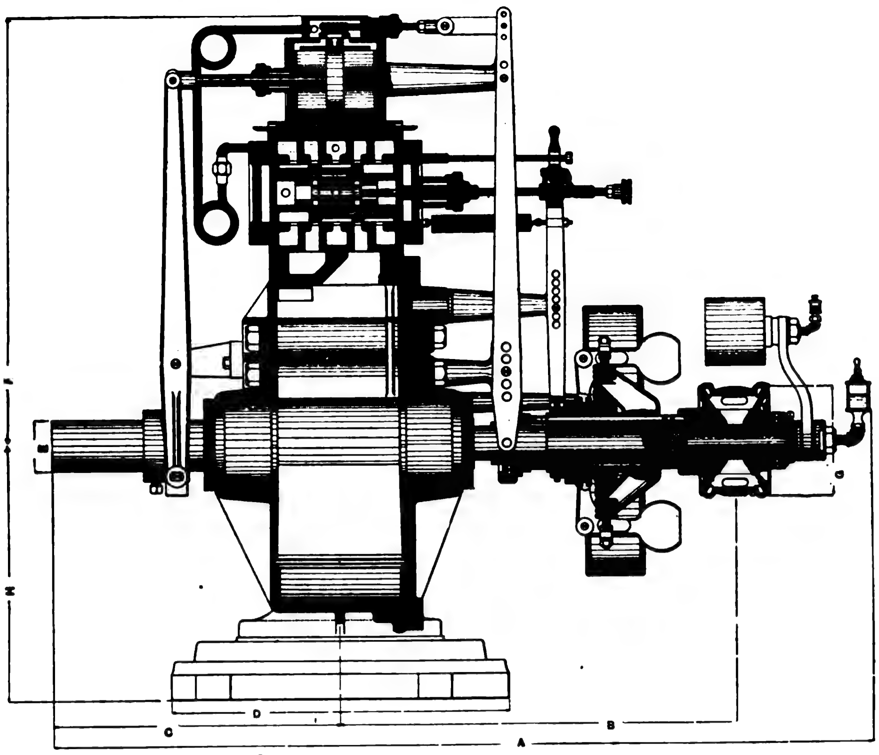

FIG. 58.—SECTION THROUGH STURGESS GOVERNOR

the gate shaft has moved. As the dash-pot is filled with water (or oil) the movement of its piston causes the dash-pot itself to slide to the right or left, moving the long lever on the right-hand side one way or the other; the lower end of this lever is connected through a sliding collar to the expansible pulley, which is expanded by movement of the lever in one direction and contracted by movement in the opposite direction. Connection is made between the main valve chamber and the valve chest of the dash-pot by means of a small pipe having two complete turns in it so as to make it flexible and allow it to follow the movements of the dash-pot to the right or the left. The operation of the governor is as follows:

If there has been an increase in load, for example, the speed of the turbine will be checked, and the centrifugal governor will move the pilot valve in such a direction as to cause the turbine gate to be opened wider by the rotary piston. As soon as the gate shaft begins to move, the cam on the left throws the dash-pot piston to the right, and this causes the contraction of the expansible pulley, which slightly increases the speed of the centrifugal governor, compensating for the drop in speed by the turbine shaft and counteracting the tendency of the governor to carry the pilot valve to the extreme limit of its travel. The motion of the dash-pot to the right causes its slide valve to uncover the ports, admitting pressure to the left of the piston and relieving pressure on the right of the piston. This checks any further advance of the dash-pot itself, and as soon as the gate shaft comes to a stop the dash-pot is gradually returned to its mid position by the pressure on the left-hand side of its piston. In returning to the central position, the dash-pot increases the diameter of the expansible pulley; this would of itself reduce the speed of the centrifugal governor and further affect the valve, but, as the result of the previous movement of the gate shaft, the turbine speed will have picked up and the increase in its speed will counteract the increase in the size of the expansible pulley and maintain the speed of the centrifugal normal. This arrangement is said to give an extreme-

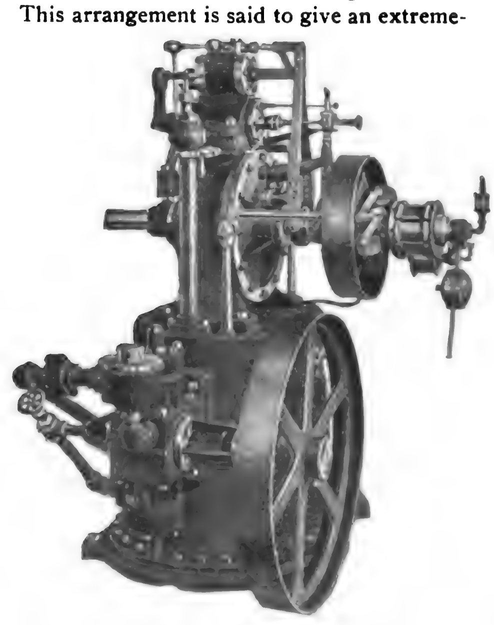

FIG. 59.—SELF-CONTAINED STURGESS GOVERNOR, PUMP AND TANK.

ly sensitive gate control and at the same time to prevent overrunning and "hunting." The rotary piston has a range of 0.87 of a revolution, so that its shaft can in most cases be coupled directly to the gate shaft of the turbine. Of course, when the gate shaft must take more than 0.87 of a revolution, the connection between the governor shaft and the gate shaft is made by means of gears of the proper ratio. The hydraulic pressure for the operation of the valves and the rotary piston is obtained from the penstock, or some similar head of water, whenever this is practicable; when it is not, a pump and receiver are supplied, and oil is used as the working fluid for the governor.

Fig. 59 illustrates the Sturgess self-contained governor, oil tank and pump, designed for places where space is limited. The tank forms the base of the governor and the pump is bolted to the side of it. The pump is a double-cylinder single-acting machine, the cylinders being coaxial and the two plungers being bolted to a common yoke.

THE ENGINE BUILDERS' ASSOCIATION.

This Association held its annual meeting in New York, December 9 and 10, the sessions being held at Sherry's Hotel, which has become the usual headquarters for these occasions. President C. A. Gates occupied the chair.

The papers read at the public sessions were on "Costs," by C. M. Lauer; "The Steam Turbine," by F. C. Bates; "Employers' Associations," by Charles L. Eidlitz, and "Salesmanship as an Applied Science," by R. U. Conger.

Mr. Lauer in his paper recommended the basing of manufacturing costs on charges for the time put in by the men and the machinery separately, making the man-hour charge 50 per cent greater than the rate actually paid the man, and basing the machine-hour charge on the investment, proportion of the shop floor-space occupied, wear and tear on the machine, and other factors actually entering into the cost of operating the machine, excepting the operator's wages, of course. The paper was discussed briefly by Messrs. John E. Sweet, W. M. Taylor, John Dick, W. D. Forbes and the author.

Mr. Bates' paper was a brief exposition of the principles of steam turbines, including some historical references, and a description of the salient features of the Parsons, De Laval, Rateau and Curtis turbines, the latter naturally receiving the most elaborate treatment; in fact, the description of the Curtis machine was very complete. The author also pointed out the advantages in generator construction that the speeds of the Curtis type of turbine conferred. The paper was discussed very slightly by Messrs. Dick, F. R. Low, W. M. Taylor and C. R. Vincent.

Mr. Eidlitz's paper was full of hard common sense and humor, and elicited much applause and merriment. The author urged that an association of employers must be led by men fitted for their responsibilities, regardless of their positions in the commercial world and any petty jealousies on the part of their business competitors in the association, and pointed out that loyalty and open purses are absolutely indispensable for success, as demonstrated time and time again by the labor unions. There was no discussion of the paper, but Messrs.

Dick and Taylor expressed their cordial appreciation of it.

Mr. Conger did not read a "paper;" he delivered an extremely interesting address without notes, but one for which he was evidently well prepared. He analyzed salesmanship, which, he declared, was practically a science, and advanced some attractive arguments as to the essential qualifications of a successful salesman.

After the regular programme was concluded, Prof. Sweet, who had been delegated to go to Washington with Messrs. William Kent and W. M. McFarland to oppose the adoption by the Government of the metric system, reported that he and his colleagues had been unable to get the House Committee to agree on a report, and that the matter had, therefore, been left in *statu quo*. He thought his committee's arguments had prevented the Government from making a favorable report, but the matter would undoubtedly come up again next year. He also made some remarks concerning the proposed substitution of the metric system for the English system in this country, and fell into the customary anti-metric error of referring to the contemplated governmental legislation as "compulsory."

The public session adjourned *sine die* at the close of Prof. Sweet's remarks. At the executive session held the following day these officers were elected for the ensuing year:

C. A. Gates, re-elected president; Thomas C. Wood, vice-president; Arthur L. Merriam, treasurer; N. B. Payne, secretary. Council: Walter C. Kerr, S. F. Bagg, N. B. Payne, C. A. Bonsall, H. C. Nichols and J. I. Lyle.

Abstracts from Foreign Contemporaries

Heating of Underground Three-Phase Cables.—Dr. R. Apt and C. Mauritius contribute an article to a recent issue of the *Elektrotechnische Zeitschrift* on the heating of underground three-phase cables. The cables upon which the first tests were made were built for voltages up to 1000, and had fiber insulation. Provided that not more than two of these be placed close together in the ground and the temperature shall not rise more than 25 degs. C., the maximum currents to be allowed for different cross-sections are given in the following table:

Sq. mm.	Amperes per phase.	Maximum current per mm. cross-section.
(3X 6)	(50)	(8.33)
3X 10	65	6.5
3X 16	85	5.31
3X 25	110	4.41
3X 35	135	3.86
3X 50	170	3.4
3X 70	205	2.93
3X 95	245	2.58
3X120	280	2.33
3X150	320	2.13
3X185	365	1.97
3X210	395	1.88
3X240	430	1.79
3X280	470	1.68
3X310	500	1.61

These values should never be exceeded. Cables built for a maximum voltage of 6000 with paper insulation were then tested. With a maximum allowable temperature rise of 25 degs. C. the maximum currents allowed are as follows:

Sq. mm.	Amperes per phase.	Maximum current per mm. cross-section.
(3X 6)	(50)	(8.34)
3X 10	60	6.00
3X 16	73	4.57
3X 25	90	3.60
3X 35	108	3.09
3X 50	130	2.60
3X 70	155	2.22
3X 95	185	1.95
3X120	210	1.75

Less current per cross-section is allowed for high tension than for low tension cables. The highest permissible current depends upon whether the increased temperature acts on the insulating material so as to decrease the perforation voltage. The fact that with increase of temperature the insulation resistance decreases is of little moment, since a high insulation resistance is no longer considered to have anything to do with the quality of the cable. From tests made by the authors it was shown that the perforation voltage changes with increases in temperature, having a maximum value for fiber insulated cables, the position of the maximum depending upon the material with which the cable is impregnated. With Gutta Percha cables the perforation voltage decreases continuously with increasing temperature. The maximum value in fiber insulated cable is, however, never reached in practice.

Lightning Conductors.—At the second general meeting of the Birmingham Architectural Association, a lecture on "Lightning Conductors" was delivered by Sir Oliver Lodge. In the course of his remarks, he stated that a copper conductor was not so good as an iron one. It did not damp out the oscillations; it let the current down too suddenly and was liable to side flashes. A small iron wire was ample protection, so long as the wire lasted. The lightning might dissipate the wire, but by the time the flash was over the conductor had achieved its purpose. It was better to have a number of cheap conductors than one or two expensive ones. But if one wanted to be absolutely immune from lightning—and there were cases when it was desirable, such as in the case of a powder magazine, or a guncotton factory—one could be so by providing a complete metallic enclosure like a banker's strong room. The only possible way to damage such a building would be for the lightning to be strong enough to melt it. The building might retain the charge, however, so that it would be as well to have sky and roof terminals. Sir Oliver then proceeded to demonstrate his lecture with a number of interesting experiments.

Starting and Regulating Resistance.—MM. Lindenstruth and O. Foster recently communicated to *L'Eclairage Electrique* an interesting article on some modern types of cheap and compactly built metal resistances for starting and regulating purposes. The gist of their communication is as follows: For resistances, which are required to absorb but small energies, the old design of spirals of resistance wires, suitably assembled, leaves little to be desired. If, this is not the case and there is danger of the coils coming in contact with each other, the spirals are often stiffened by a rod of slate or a tube of asbestos placed inside the coil. It is stated as a general rule that rheostats for continuous service should be designed with a view to perfect ventilation, while rheostats for intermittent use are best designed with a metal cover, which quickly absorbs and slowly dissipates the heat given off by the resistance. Fig. 2 shows a very compact pattern of resistance for continuous service, suitable for small currents. The resistance wire passes spirally from one of the grooved porcelain pieces, *b b'*, to the other, these two porcelain pieces being held apart by a plate, *a*, of iron, slate or asbestos. Iron is preferred because of its strength and its ability to dissipate heat rapidly. Iron plates are also used in the design shown by Fig. 3. Fig. 1 shows another type of resistance, in which the ac-

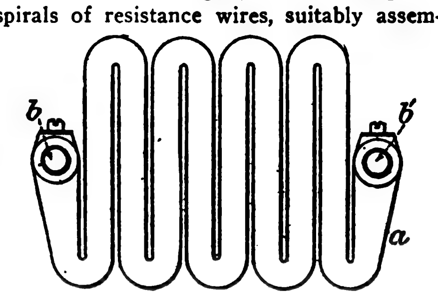

FIG. 1.

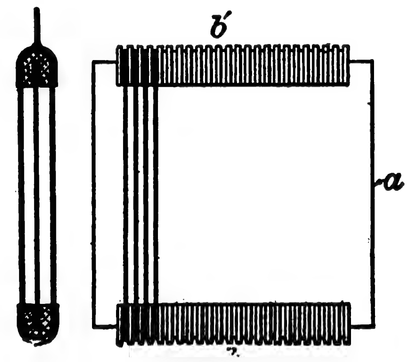

FIG. 2.

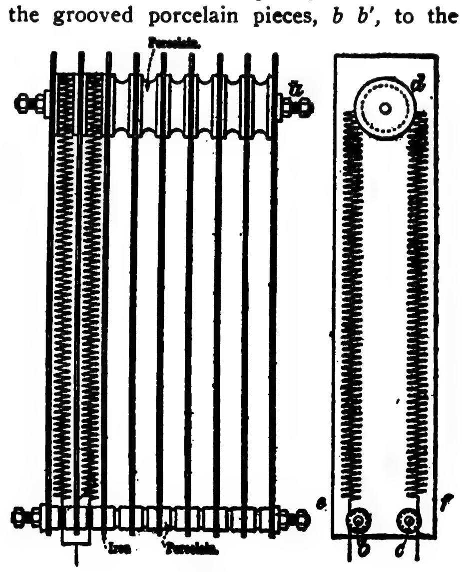

FIG. 3.

tual resistances are usually cast. For heavy currents the type shown in Figs. 5, 6 and 8 is preferred. As shown in the sketch, Fig. 5, the resistance takes the form of metal strips, *b*, which are clamped at their upper ends to a series of cross-supports, *a*. The strips are mounted zig-zag, and are kept in position by the arrangement indicated in Fig. 8. A resistance designed upon these lines has been used for regulating the speed of a three-phase 1500-h.p. 6000-volt motor. The speed limits are 125 and 150 r.p.m., and the regulation is obtained by inserting resistance in the stator circuit. Fig. 4 shows a design of resistance for intermittent use. The outer tube is of iron and lined with asbestos. The resistance coil is introduced while still wound on the mandril, but when the latter is withdrawn the coil expands and presses firmly against the asbestos lining. Subsequently the tube is filled with a suitable cement. Another form often used consists of a spiral of a long, flat resistance strip wound like the spring of a clock, asbestos or mica being wound together with the metal strip so as to separate the individual turns. Several resistances constructed in this way may be connected as shown in Fig. 9. A similar but more open construction is shown in Fig. 7.

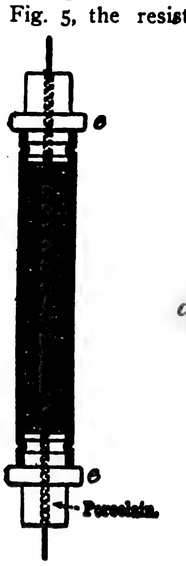

FIG. 4.

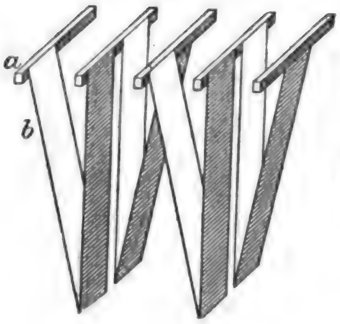

FIG. 5.

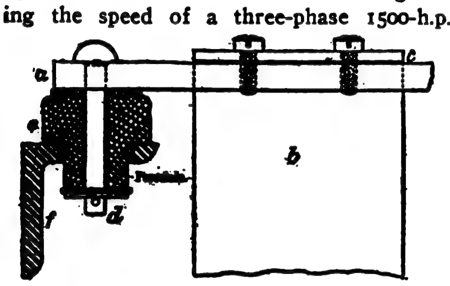

FIG. 6.

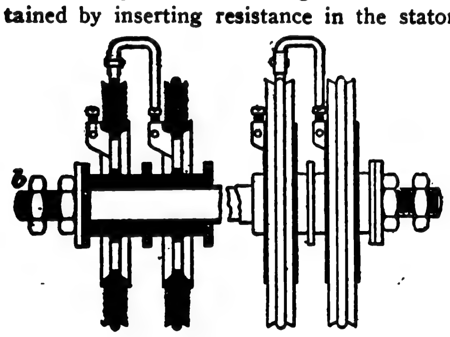

FIG. 7.

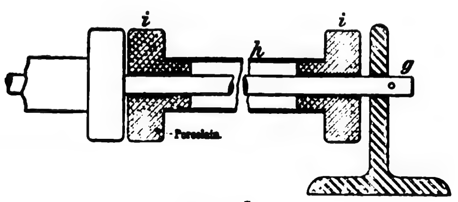

FIG. 8.

Maximum Current Permissible in Direct-Current Cables.—Dr. H. Kath contributes to the *Elektrotechnische Zeitschrift* the report of the committee appointed by the Union of German Electricity Works and by German cable manufacturers which

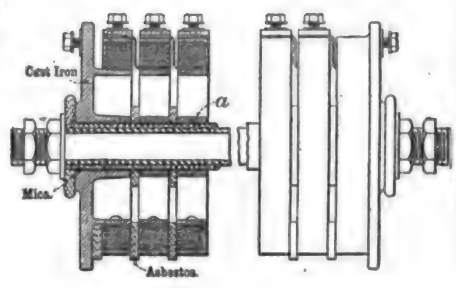

FIG. 9.

has been adopted by the German Association of Electrical Engineers. The committee gives the following formula for the maximum current, which may be allowed in single direct-current cables:

$$J = c \sqrt{\frac{q\,t}{\log \dfrac{4\,l}{d}}}$$

In this formula J is the maximum current permissible; c is a constant, the value of which was found from numerous experiments to be 11.55; q is the cross-section of the copper core in sq. mm.; t is the increase in temperature in degrees Centigrade of the cable core, which is taken at 25 degs. in calculating the following figures; l is the depth in mm. below the surface, where the cable is laid and is taken as 700 mm. in the following figures d is the diameter in mm. of the copper core. The following table gives the figures for direct-current cables laid in earth, the first column giving the cross-section and the second column the maximum current permissible with a difference of potential of 700 volts.

Cross-section in sq. mm.	Amperes.
16	140
25	175
35	215
50	260
70	315
95	370
120	420
150	475
185	530
240	615
310	705
400	810
500	920
625	1040
800	1190
1000	1350

The current given in the table should not be exceeded, and the figures hold good as long as there are not more than two cables in close proximity in the earth. Neutral wires are not considered as cables. If the considerations for the dissipation of the generated heat be unfavorable or if a great many cables are crowded in the earth, it is recommended to make the permissible current three-fourths the value given above.

Current Regulator.—A form of improved apparatus for automatically regulating the current in electric lighting installations is shown diagrammatically by Fig. — herewith, taken from *Engineering* of London. In the sketch, *E* represents a motor used to regulate the field excitation of the dynamo *D*. The winding of the motor is composed of two separate sets of coils, *A* and *V*. The set, *A*, is supplied with current from the battery, *B*, and the set, *V*, is supplied with current flowing in the opposite direction to that in the set *A*. By the influence of these two coils the motor, *E*, whose armature is connected with the field coils of the dynamo, *D*, is caused to shift the controlling lever, *H*, of the resistance, *R*, for regulating the field excitation of the dynamo, in accordance with the varying speed of the dynamo, and the varying number of lamps in circuit until the two coils, *A*, *V*, balance each other in their magnetizing action. Consequently, the battery, *B*, will be supplied with current which will be, under all conditions, in a determined proportion to the number of lamps switched on. For the purpose of safeguarding the lamps

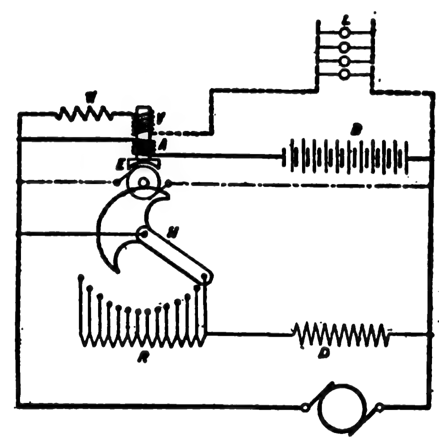

FIG. 10—CURRENT REGULATOR.

against the increase in potential which is produced at the terminals of the battery, *B*, and is due to the action of the internal resistance of the latter, according to the current strength supplied to the battery, there is included in the conductor leading to the lamps a resistance, *W*, which produces a fall of potential at the lamps, *L*, of such an amount that by its means the increase of potential that takes place at the terminals of the battery, according to the strength of the charging current, is rendered harmless, and the lamp potential remains constant in all cases.

Oil for Transformers, Switches, Etc.—E. K. Scott contributes to the London *Electrical Review* a short article on oil for transformers, switches, etc., based principally upon American practice. There are various methods of drying, but perhaps the best one is to place the oil in a large tank having a resistance coil suspended in the center. After the current has heated up the oil, air is blown through it from a motor-driven compressor, the air having been first thoroughly dried by passing it over chloride of lime. As the small bubbles pass upward through the oil they take up any moisture that may be present. In the case of a very

large tank, it is as well to also agitate the oil mechanically, so as to insure all of it coming into contact with air. After drying, a flashing test is made, and this, of course, varies according to the voltage to be employed. It may be taken, however, that no oil is considered satisfactory which will not withstand at least 30,000 volts alternating between two flat surfaces 1½ in. in diameter and 1-5 in. apart. Oil is an absolute necessity for high-tension switches. In very cold weather the oil may become thickened. As a cure for this the General Electric Company recommends tetrachloride of carbon with oil.

Ball Bearings for Electric Motors.—In order to improve the efficiency of electric motors, an English company has introduced small motors fitted with ball bearings of an improved type, whereby the losses due to friction are reduced, great saving is effected in the consumption of oil, and the space occupied is less than for motors fitted with ring lubricated bearings. Instead of filling the whole space between the inner and the outer rings with balls, as hitherto, a smaller number is provided, the spaces between the balls being fitted with springs, as shown by Fig. 11 herewith

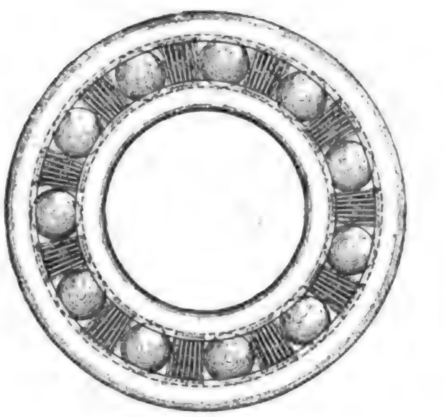

FIG. 11.—BALL BEARINGS FOR MOTORS.

taken from the *Electrical Engineer* of London. If, in consequence of the bend of the shaft, there is a tendency for the outer ring to get out of true with the inner ring, the variation in the speed of the balls is counterbalanced by the action of the springs, so that the balls will not be damaged. A further advantage of the design is that the springs are filled with felt, which forms a rotating lubricating machine. Easy access to the balls is provided for purposes of inspection.

Measuring Magnetomotive Forces.—London *Electrician* contains an illustrated description of Rudolf Goldschmidt's method of measuring magnetic potential drop, which was devised to test actual steel field magnets which were suspected of being faulty in quality and casting. The principle is as follows: To measure the magnetic potential drop between the points *a* and *b* in the yoke of a direct-current machine, two laminated iron cores, *AC* and *BD*, are placed on *a* and *b*, respectively, in the manner shown, the gap, *CD*, being from ¾ in. to ⅞ in. By this arrangement a small magnetic shunt is formed to the yoke which will take up a small amount of the magnetic flux. Point *C*, for instance, will indicate north polarity, point *D* south polarity, and a small compass needle placed between *C* and *D* will assume a position pointing with its south pole to *C*. The coils, S_1 and S_2,

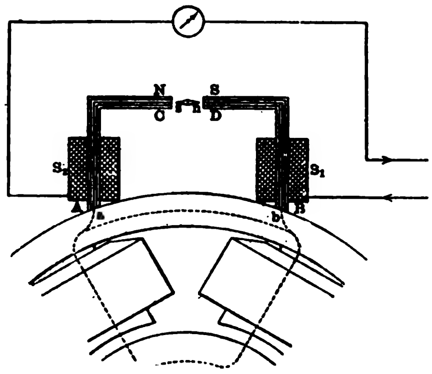

FIG. 12.—MEASURING MAGNETOMOTIVE FORCES.

are so excited as to counteract the magnetic potential between *a* and *b*. If the ampere turns, S_1 and S_2 are increased sufficiently to overpower the magnetic force of $a — b$, then the flux in the magnetic shunt would reverse, the polarity of *C* would become north and the polarity of *D* south, and the compass needle

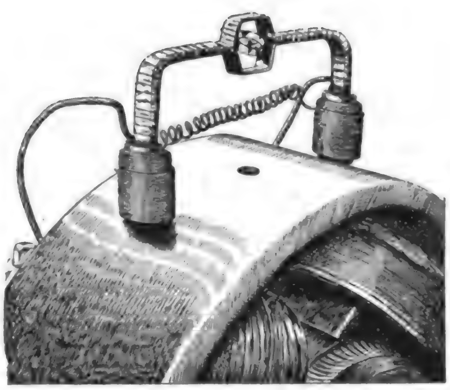

FIG. 13.—MEASURING MAGNETOMOTIVE FORCES.

would point in the opposite direction. If the current in S_1 and S_2 be so adjusted that the compass just begins to move from one position to the other, the magnetomotive force of the coil is equal to the difference of potential between *a* and *b*, and thus represents directly without any further calculation the amount of ampere turns required to drive the flux through the yoke of the machine. Fig. 13 shows the method applied to the yoke of a direct-current machine, and

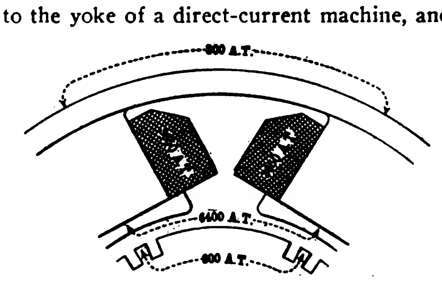

FIG. 14.—MEASURING MAGNETOMOTIVE FORCES.

Fig. 14 shows a diagrammatic sketch of the magnetic circuit with the figures inserted as they were actually determined by the apparatus. To shield the compass needle from the influence of undesirable stray lines, the compass may be surrounded by a small iron box, as shown. Other applications are as follows: Measuring the drop for the different yokes and parts of a direct-current machine so as to detect irregularities and blow-holes in the iron; getting the full magnetic curves of the armature teeth of electrical machinery; detecting bad joints in any part of the yoke of direct-current machines. The method may also be applied to measuring the direct-current in a conductor, say, a feeder cable, without inserting the ammeter or cutting the cable in any way. The author states that the method is sufficiently accurate for all practical purposes.

Distribution of Electrical Energy—At a recent meeting of the British Institute of Civil Engineers, J. F. C. Snell presented a paper on "Distribution of Electrical Energy," which is abstracted in *Engineering* of London. After dealing with the limits of pressure, as defined by the Board of Trade, and the results of the work of the Engineering Standards Committee in settling upon standard periodicities, the systems of supply are more thoroughly criticized, and the single-phase system is set aside as being inapplicable for general supply, as is also the direct-current high-tension system. The author is of the opinion that the distributing systems which are likely to be adopted in the future are:

1. Direct-current, two or three-wire, for small districts.
2. Single-phase high-tension for railways.
3. Two-phase high-tension generation and low-tension distribution (for existing single-phase systems of general supply).
4. Three-phase high-tension generation and direct-current low-tension distribution (for existing direct-current systems in large districts, and for railways of short length).
5. Three-phase high-tension generation and low-tension three-phase or six-phase distribution (for entirely new and large districts).

Diagrams accompanying the paper demonstrate the economical radii of supply by direct current at 500 volts for different loads transmitted and by the high-tension substation method, the result being that above the under-mentioned distances the high-tension method is more economical, viz.:

Kilowatts.	Radius. Miles.
250	1.6
500	1.25
1000	1.06

With regard to the effect of storage at sub-stations, the author believes that storage will be more largely resorted to in the future; and figures are given in support of this view. He then proceeds to discuss the economical limit of pressure for high-tension supply by underground cables; and gives curves to show that for general purposes, in Great Britain, 6600 volts is, approximately, the economical pressure. The effect of the cost of insulation of extra high-tension cables is also discussed. The paper next deals with the cost of overhead transmission of high-tension currents, and reasons for fixing upon a pressure of 20,000 volts in England are given.

Dielectric Strength of Certain Specimens of Mica.—Messrs. E. and W. H. Wilson contribute to the London *Electrician* the results of tests made by them on certain specimens of mica, the object of the tests being to determine the dielectric strength. The method of test was to place each sheet between two circular bronze electrodes, each 1 in. in diameter and 1-16 in. thick, and to raise the difference of potential between them by aid of a transformer until the specimen broke down. The frequency was 55, and the difference of potential was raised by increasing the exciting current of the alternator. Each test was performed as quickly as possible, but in the case of the micas having the higher dielectric strength there was slight local heating due to the electric discharge at the edge of the discs consequent upon the increased density of the electric force produced there by the presence of the mica. In some cases nine specimens of one kind were broken down.

Causes of Explosions in Cast-Iron Steam Valves. —Considerable attention has been given to the subject of cast-iron steam valves, during the past ten years, says M. Sylvain Périssé, in *Le Génie Civil*. The theory has been that, on opening a valve which has been shut for some hours, the condensed water is projected forward by the live steam, and thus produces intense pressure by reason of its momentum, and that the actual rupture is facilitated by the shocks caused by the violent condensation of the live steam when encountering the water. The results of some experiments by Mr. Gurlt, on behalf of the German Government, are given, and these show that when steam at a pressure of 71.1 pounds per square inch encounters cold water, the pressure produced may be as much as 925 pounds per square inch; mention is also made of the violent detonations noticed by Mr. Raymond under somewhat similar circumstances. Three accidents are detailed, one at Villefranche in August, 1897, one at Tourcoing in January, 1898, and one at Vervicq in June, 1898. In all these cases there appears to have been negligence in blowing off the condensation water, and the cause of the accidents is not far to seek. The author then cites two accidents, one in a flour mill at Pornic, and the other in a brewery in Paris, where the cause of the disasters is not so clear, owing to the fact that great care was plainly taken to get rid of condensed water. A detailed account is given of a fatal accident in May, 1901, at an electric station in Paris—an accident which the author was deputed to investigate. In this case the valve was placed 12.6 in. from the top of a vertical pipe, the diameter of which was 6.3 in.; this pipe was joined at the upper end to a horizontal main steam pipe of a diameter of 11.80 in. Drain cocks were provided in the main pipe, but there was sufficient space above the valve to store 1.43 gallon of water. When the accident happened the valve had been closed for eight hours, and, although all precautions were taken and the valve itself opened very gradually, a rupture ensued. By way of accounting for the accident, it is pointed out that when steam under pressure is allowed to expand adiabatically there must be a liberation of energy, and a table is given to show that, with an initial pressure of 14.2 pounds per square inch, 7067 foot-pounds of energy can theoretically be produced by every pound of hot water, while, with an initial pressure of 170.6 pounds per square inch, no less than 54,392 foot-pounds of energy is possible. The author is of the opinion that a small by-pass should be fitted to all valves on a vertical or an inclined steam pipe.

Some Recent Electrical Patents

Tank Float Switch. —Fig. 1 illustrates a simple mechanism for use chiefly in connection with the main switch of a pump motor supplying fluid to a tank or other vessel in which it is desired to keep the level of the fluid between certain high and low limits. The switch is controlled by a float, *N*, which swings a pivoted arm, *G*, to and fro, as the fluid level in the tank (not shown) varies. The arm, *G*, carries a slider, *J*, which is pressed outwardly by the spring coiled around it, and carries a roller, *L*, which travels along the face of an arc-shaped cam, *B*. The switch blade, *F*, is attached to an extension arm of the cam. The sketch shows the switch open; as the fluid level in the tank falls, the float, *N*, is lowered, but the switch is not affected until the roller, *L*, passes the center of the cam-face; as soon as this occurs, the spring, which is gradually compressed by the downward travel of the roller along the cam-face, forces the slider, *J*, outward and shifts the switch arm, putting the blade, *F*, into the jaws. This starts the motor, and the tank is gradually filled again; when the float is lifted far enough to carry the roller, *L*, above the center of the cam-face, the spring opens the switch. It is evident that both the opening and closing of the switch are accomplished with a suddenness that prevents either "tipping" or dragging an arc at the jaws. Patent No. 776,521.

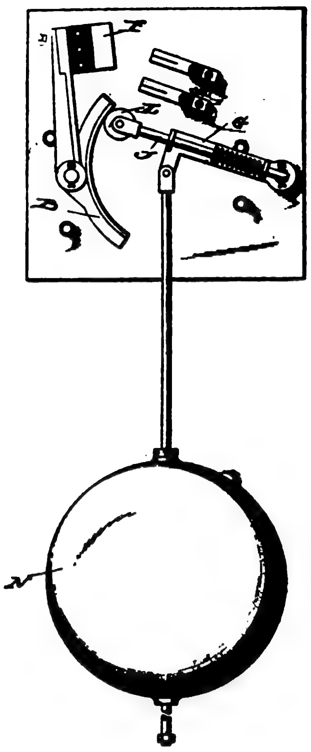

FIG. 1.—TANK FLOAT SWITCH.

Danger Signal for Elevator Gates.—Fig. 2 is a diagram showing in principle the application of a danger signal for elevator gates of the drop type, which has been invented by Mr. Charles T. Eaton, East Somerville, Mass. At each landing there are switches, *H*, *H*, and *C*, connected in series in a bell circuit; the groups at the different landings are connected in parallel to the bell main, *B*. The rising and falling gates, *G*, are provided each with a lug, *L*, to engage with a stop, *K*, on the car, *D*, when the car is at a floor and the gate is raised, as shown at the second floor in the diagram. The gate is heavier than its counterweight, *M*, so that when the car leaves the landing and the stop, *K*, releases the gate, the latter

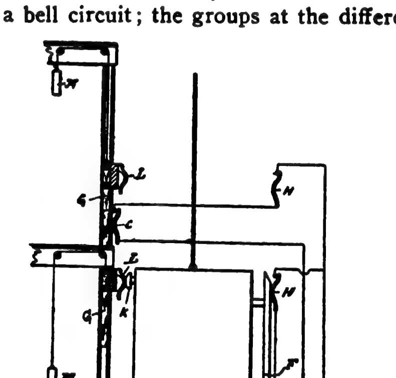

FIG. 2.—SIGNAL FOR ELEVATOR GATES.

drops to its closed position. In that position, it opens the switch, C, on its floor, and prevents the switch, H, on that floor from ringing the alarm bell. Should the gate stick, however, after the car leaves the floor, the switch, C, will remain closed, as shown at the second floor; the switches, H, H, which are held open by the skate, F, while the car is at or near the landing, are released when the car clears the landing, and their closure rings the alarm bell, the circuit being intact through the gate switch, C. It is difficult to see of what utility the system could be in preventing persons from walking through the open gate unless the bell were of such size as to be heard all over the building. The usefulness of the skate, F, is also obscure. Patent No. 777,612.

Wiring Cleat.—The cleat or clamp from an insulator knob for electric wires is familiar to those interested in such matters. Fig. 5 illustrates a new form of this type of knob which has been patented by Mr. E. C. Hunt, of Belle Plaine, Iowa. The insulator comprises a knob and a cap, both grooved on their abutting faces to receive the wire and also provided with a groove in the knob and a corresponding ridge on the cap to serve as a sort of pivot and ficilitate the clamping of the wire when a screw is set through the hole in the center into the material upon which the knob is mounted. The principal feature, however, is the shape of the central hole through the knob portion; the hole is round at the clamping face, but widens progessively into an oblong section at the back end, as shown at I in Fig. 3; the object of this is to allow the screw to be set at an angle, as shown here, whenever that may be necessitated by local conditions. The foce of the knob from the fulcrum ridge, C, to the extreme edge is slanted, as indicated at H,

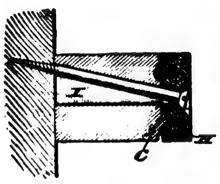

FIG. 3.

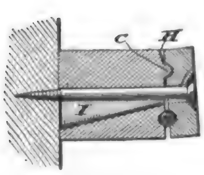

FIG. 4.

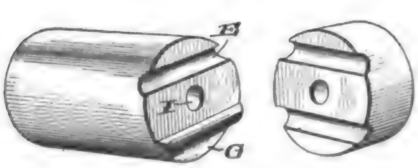

FIG. 5.—WIRING CLEAT.

Fig. 4, in order to give room for the tilting of the cap when a larger wire is clamped in the wire groove. This is shown in Fig. 4, which also shows the retaining screw set in straight, as it would be under ordinary conditions. Patent No. 776,514.

CENTRAL STATION ENG NEERS.

III.

Charles L. Edgar.

Charles L. Edgar was born December 23, 1860, at Griggstown, N. J., a small village on the line of the Delaware and Raritan Canal. His early education was such as the district school at that time afforded, and after reaching adult years he prepared for Rutgers College, which he afterwards entered and from which he graduated with honors in 1882. After graduation he took up post-graduate work in electrical engineering at Rutgers under Professor Francis Cuyler van Dyck, and in January, 1883, applied to the Edison Laboratories at Menlo Park, N. J., for employment. He was sent to the Edison Machine Works on Goerick Street, New York City, where he remained nine months. From here he was transferred to the works of the Bergman Company, manufacturer of central station apparatus, where he remained only a month, entering the service of the Edison Company, where he was employed until 1887 in general engineering work and installing small central stations throughout New York and Pennsylvania. In August, 1887, he was sent by the parent company to Boston as superintendent of the Edison Electric Illuminating Company of that city. Two years later found him general manager and early in the 90's vice-president. He retained the vice-presidency and general managership of the company until 1900, when on the death of Jacob Rogers, he became president of the company, which office he still holds. Mr. Edgar was president of the Association of Edison Illuminating Companies for 1893, 1894 and 1895, and was thrice vice-president of the National Electric Light Association, succeeding to the presidency of the latter organization in 1904. For the past three years he has been president of the Massachusetts Electric Light Association, and he is at the present time chairman of the Boston branch of the American Institute of Electrical Engineers. His ability as a central station manager is evidenced by the wonderful growth of the Edison Company, of Boston, under his management, and it is due to his progressive methods that the company stands to-day as the exponent of all that is modern in central station practice. The introduction of the vertical engine and the storage battery into the equipment of central stations are features with which his name has been actively associated. With a view to thoroughly investigating the subject of vertical engines and storage batteries, Mr. Edgar made two trips to Europe, and as the result of his investigations the vertical engine was adopted by the Edison Company, and storage batteries were first used as a central station adjunct in Boston. In 1898 Mr. Edgar visited England for the purpose of studying the Wright demand system of charging, and on his return the system was adopted by the Boston company, and is still in use there. Mr. Edgar has made several other trips abroad for the purpose of investigating foreign methods, and has given his company the benefit of such features as could be advantageously applied, especially in the line of central station construction. Mr. Edgar is a man of pleasing personality, and one whose influence is felt by all with whom he comes in contact, both socially and commercially, and despite his remarkable success he retains the most democratic characteristics. One of his most remarkable qualifications is his ability to observe and control the most minute details connected with the vast business of which he is the head.

CHARLES L. EDGAR.

NOTES.

An Electrolytic Telephone.—In connection with the Jubilee Exhibition held by the German Electrical Society in Berlin, Mr. E. Ruhmer exhibited a rather curious apparatus in the shape of an electrolytic telephone receiver. This apparatus consists mainly of an electrolytic cell containing electrodes of unequal size. On being traversed by microphone currents, this cell reproduces any words spoken into the microphone to which it is connected.

A New Suggestion for Peat Utilization.—Attempts have been made for a long time to utilize the enormous stores of peat possessed by many European countries. Now a Galician engineer is said to have succeeded in working peat into fuel by the addition of naphtha; tests of the product are said to have shown it to be a perfect equivalent of brown coal. Further tests made at the laboratory of Lemberg University have brought out the fact that common raw

oil or preferably the waste from oil refining may be used in the place of naphtha, thus further reducing the cost of manufacture to a considerable extent. According to calculations made at the peat utilization department of the State Agricultural Experimental Office of Vienna, the heating value of peat worked with oil waste is even higher than in the case of an addition of naphtha. The inventor submitted his products to a commission of experts at Berlin, by whom they were judged favorably. Applications have been made for patents covering the process.

The Interstate Independent Telephone Convention—The fourth annual convention of the Interstate Telephone Association was held at the Auditorium Hotel in Chicago on December 13, 14 and 15. Interesting papers were presented by Theodore Thorward, of South Bend, Ind.; E. D. Graham, of Mexico City, Mo.; Mr. J. H. James, of Mankato, Minn., and Rome C. Stephenson, of Rochester, Ind. The election of officers resulted as follows:

President, Theodore Gary, of Macon, Mo.; vice-president, William R. Fee, Milford, O.; secretary, L. L. C. Brooks, St. Paul, Minn.; treasurer, A. B. Conklin, Aurora, Ill. The executive board recommended consisted of Hon. C. E. Hull, Salem, Ill.; S. S. Lichty, Clinton, Iowa; J. G. Splain, Pittsburg, Pa.; Richard Valentine, Janesville, Wis.; W. Mathews, Maysville, Ky.; E. D. Graham, Mexico, Mo.; Charles W. Wells, Marion, Kan.; H. A. Barnhart, Rochester, Ind.; W. Gray Jones, Columbus, O.

Electric Power Transmission in a Motor Launch.—The use of oil engines jointly with electric motors for the driving of automobiles is now well known, numerous systems of such mixed operation having been developed in recent years. Now an interesting attempt to use a similar combination for the propulsion of motor boats is being made by the Companie de l'Industrie Electrique et Mécanique, of Geneva, Switzerland. The General Navigation Company of the Lake of Geneva is having built a boat intended for freight service on the lake, the power necessary for the propulsion of the boat, as well as for working the capstans, being supplied by a Diesel engine built by the Sulzer firm. The engine runs only in one direction, and at a fixed speed, and special means are provided to secure the starting, acceleration or retardation of speed, and reversing of the propeller. These consist of an electric generator and an exciter dynamo mounted on the shaft of the Diesel engine, an electric motor mounted on the propeller shaft, and an electromagnetic clutch between the ends of the engine shaft and the propeller shaft, the two being in axial alignment, of course. In starting, the engine shaft is unclutched from the propeller shaft and the engine brought up to normal speed in the usual way. Then the generator and motor are excited and the latter brought up to speed by means of a controller, if full propeller speed is desired; the two shafts are then clutched and the generator and motor are "killed" in order to avoid their internal losses; the exciter continues active, as it energizes the clutch. For reverse running, at all speeds, the shafts are unclutched and the propeller driven by the motor. This is also done for forward running at speeds below the maximum.

The National Electric Light Convention—The electrical fraternity throughout the entire Middle West has united to entertain delegates to the convention to be held by the National Electric Light Association in June. The convention will be held in Denver, but all of Colorado's neighboring states are interested in making it a success, and in giving the delegates the best entertainment ever provided for any convention. Two preliminary committee meetings have been held. At the first the central station men decided, with President Ernest H. Davis, that the business sessions should be held in Denver. Colorado Springs was such a close competitor for the meeting that it was decided to take the whole convention to that city for two or three days of entertainment, and those present from other cities said that they intended to entertain parties of delegates, so that arrangements can be made by delegates to visit any particular section, with the assurance that they will be cared for properly. After the first preliminary meeting Mr. Davis appointed Mr. Henry L. Doherty, president of the Denver Gas & Electric Company, as the representative of the National Association in the West, to take charge of the arrangements for the convention, and Mr. Doherty has secured the co-operation of the central station men, the business men and the railroad men in this work. The hotel men say that every effort will be made to care for the delegates properly, and that rates will not be increased in any way. The railroad men say that low rates can be assured for the meeting; one fare for the round-trip from Chicago, St. Louis and points in that vicinity, and for that portion of the trip east of these points, a round-trip fare of one and one-third times the single fare. It may be possible to obtain even lower rates, though the schedule assured means a good time limit.

Evening Courses in Electrical Engineering.—The Polytechnic Institute of Brooklyn (N. Y.) has inaugurated a series of evening lectures in electrical engineering, the first lecture having been delivered on December 15. The course covers four lectures on Commercial Engineering, by Mr. Charles F. Scott, consulting engineer of the Westinghouse Electric & Manufacturing Company; eight lectures on Central Station Practice, by Mr. W. S. Barstow, the well-known consulting engineer; eight on Electrical Power Transmission, by Dr. F. A. C. Perrine; eight on Electric Traction, by Dr. Louis Duncan, and eight on Telephony, Telegraphy and Patent Practice, by Mr. Thomas D. Lockwood, of the American Bell Telephone Company.

Mr. Barstow delivered his first two lectures on December 15 and 21, and Mr. Scott delivered his first one on December 21; the remaining lectures by these two gentlemen are to be as follows: Mr. Barstow, January 5, 17 and 31, February 14 and 28, and March 14; Mr. Scott, January 25, February 16 and March 16. The subject of Mr. Barstow's first lecture was "Local Conditions Governing the Selection of the System." The speaker took up in detail the preliminary determinations which a consulting engineer should make before recommending and laying out a central station for lighting and power work, such as determining the character of the community, its past and probable future growth, franchise conditions, the location of the station with reference to fuel and water supply, cost of labor, etc. The lecture was extremely interesting, since it was really devoted to a practical consideration of some of the problems which the consulting engineer must meet in every-day work. Pamphlets containing the full lists and all information concerning the lectures may be had on application to Dr. F. W. Atkinson, president of the Institute.

Some Difficulties in Getting On is the title of an extremely interesting address delivered recently to the students of the Institution of Electrical Engineers, of Great Britain, by Mr. James Swinburne, past president of the Institution. Mr. Swinburne pointed out two vital facts relating to technical education—one, that teachers of science seem to think that the practical application of their science is degrading and business ability is to be despised; the other, that the natural tendency of educational institutions is toward the unpractical, for the reason that graduates of such institutions who have good practical judgment in the application of their learning go out into the world and apply it, while the teachers of the succeeding generation are men devoid of the characteristics which make successful business men, engineers, etc. As to the pursuit of knowledge, says Mr. Swinburne, "No knowledge is worth obtaining for its own or any other sake unless it is or probably will be useful to man." Concerning engineering work, Mr. Swinburne commends an "American definition of an engineer," which he says is "a man who can do for one dollar what any fool can do for two." This, he says, "is not poetical, and it is useless for oratorical purposes, but it is right." Scientific training and knowledge are priceless, he says, but "every design, every engineering manufacture, every piece of engineering is only a question of price. It is unpleasant, perhaps, but it is a hard fact, and we have got to face it. If one of us earns £100 a year and does £150 worth of work, he is efficient, but if he only does £90 worth he is inefficient, and will come to grief." As to hard work: "A hard struggle is a very good thing for a young man who has anything in him. It gets him into the way of overcoming difficulties, so that when he gets above the small obstacles he goes on overcoming large ones from mere force of habit."

We regret very much that space limitations prevent the publication of the entire address; it is well worth study by budding engineers.

ESTABLISHED 1889.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED

Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the

McGRAW PUBLISHING COMPANY,

114 Liberty Street, New York.

Philadelphia Office............929 Chestnut Street
Chicago Office..............Monadnock Building
Cleveland Office..............Cuyahoga Building
London Office, Hastings House, Norfolk St., Strand

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal.*

Address all business communications to AMERICAN ELECTRICIAN, 114 *Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, draft, express or postal money order, payable to McGraw Publishing Company.

Entered in the Post Office at New York as second class mail matter.

Vol. XVII. JANUARY, 1905. No. 1

Of this issue, 20,000 copies are printed. The total number of copies printed in 1904 was 217,000, or an average of 18,083 copies per issue.

CONTENTS.

The New Year.

It gives us much pleasure to greet our readers and other friends on this the ninth New Year's Day since *Electrical Industries* became the AMERICAN ELECTRICIAN. We print elsewhere in this number letters, from business establishments distributed throughout the country, concerning the business conditions during and at the close of 1904. The opinions expressed have not been modified in the slightest degree by the editorial blue-pencil, nor have any communications been omitted. In view of these facts, the letters published may be considered to reflect the general sentiment throughout the electrical and allied trades, and judging by the great preponderance of optimistic opinions among the writers, 1905 should be a great improvement over the year just closed, if it does not inaugurate an era of prosperity similar to that enjoyed a few years ago. However this may be, we sincerely wish for the electrical fraternity a bountiful measure of success and a continuance of the progress which has carried American electrical industries to the front of the international ranks.

Difficulties in "Getting On"

On a preceding page we print a few excerpts from an address recently delivered by Mr. James Swinburne to a body of English students. This address contained much valuable advice, and we regret the impracticability of reprinting it in full. Among the hints delivered by the author, we note a strong recommendation to specialize, but not too narrowly. This may be difficult, and it is frequently the case, says Mr. Swinburne, that a man is buffeted about and prevented from taking up immediately the special work for which he is best equipped, or which he prefers. As we have pointed out in these columns before, it is better to know one thing perfectly, without much other knowledge, than to have a superficial smattering of several or many things without a "working" knowledge of any. What one's specialty is to be is too often determined by chance, but it is not wholly impossible to work into the right direction by dint of hard struggling and perseverance; success worth having is never attained without plenty of hard work and discouragement. On this point Mr. Swinburne said: "Nearly all great men rise from almost nothing with infinite trouble in their youth. There is nothing worse for a young man than to have about $1000 a year of his own; if any of you has this sort of private income he had better go into partnership in installation work for a year or two, and then begin his business seriously." This advice is excellent in the main, although we do not quite follow the intimation that installation work is not serious business—it certainly is in this country.

Mr. Swinburne gave educational institutions a hard knock, and while conceding the value of the learning obtained from those institutions, dwelt with undue force on the unpractical nature of their faculties. It is, of course, true that college professors are not practical engineers, as a rule, their ranks being ordinarily filled by men who have either no taste or no ability for actual engineering work. But there are notable exceptions to the rule, and we scarcely think Mr. Swinburne's argument that each generation of pedagogues is more unpractical than the preceding one is tenable, unless the conditions in this respect are vastly worse in Great Britain than here. If a college professor can be an engineer, or a physician, or a lawyer, as the case may be, so much the better for his students; but even without any of the qualities that would make for success in the application of his learning, if he has the ability to impart his knowledge to his classes, the benefit to those classes is priceless.

The High Voltage Incandescent Lamp.

The development of the 220-volt incandescent lamp has not effected the changes in central station practice in this country that were generally expected when its advent was first announced. Most stations of medium and small size continue to use 110-volt to 120-volt lamps, employing three-wire distribution when distance makes two-wire circuits impractical, and all of the large stations of which we have knowledge, excepting the one in San Francisco, use the three-wire system for all direct-current incandescent lighting. The prime reason for the continuance of the 110-220-volt, three-wire distribution by the big stations is obvious; their underground mains are all laid that way and the cost of changing over would be prohibitive, even if the high-voltage lamp justified it otherwise. In smaller stations, however, the reason for not changing over is not so immediately apparent. The high-efficiency 220-volt 16-c.p. lamp takes only 60 watts, as compared with 50 watts for the same class of 110-volt lamp, and it would seem that the saving in copper and balancing apparatus would compensate for the difference in the economies of the two lamps. In actual practice, how-

ever, we doubt that this would be true in any considerable percentage of cases.

A rough idea may be obtained by considering the chief differences between a plant having a 500-kw. lighting load peak, using 110-volt lamps on a three-wire distribution system, and a plant of the same lamp load using 220-volt two-wire distribution. Assuming in both cases that the peak covers two hours, that the average load during the remainder of the 24 hours is 16 per cent. of the peak load, and that 85 per cent. of the lighting load is in incandescent lamps—which assumptions are as favorable to the high-voltage lamp as one could reasonably expect—we get the following approximate data. The incandescent part of the peak load will be 425 kilowatts or 8500 lamps; the average during 22 hours of each day will be 85 kilowatts, or 1700 lamps; the generating plant must have a maximum capacity of 500 kilowatts and balancing apparatus of about 50 kilowatts capacity will be required. If the distribution mains contain $17,000 worth of copper devoted to the lamps alone, about $4000 of this will be in the neutral conductors. The generating plant, steam and electrical, at $110 per kilowatt will cost $55,000, and the balancing apparatus, involving no steam apparatus, will cost about $1000 installed. At a cost of 2 cents per kilowatt-hour for energy at the switchboard during the peak and 4 cents during the remainder of the 24 hours, the current operating cost will be $85 per day of 24 hours. The interest and depreciation on the balancing apparatus and neutral conductors will be at least $400 per annum—say, $1.10 per day; that on the remainder of the station apparatus will be about $6000 per annum—say, $16.40 per day. The items mentioned will foot up $102.50 per day.

On the foregoing basis, the two-wire 220-volt plant will have a peak load of 585 kilowatts, and an average load for 22 hours of 97.5 kilowatts, owing to the difference in lamp efficiency, and the operating cost will be $109.20 per day. The interest and depreciation on the generating plant will be about $6500 per annum, or $1.75 per day, making the total charges under consideration $110.95 per day as compared with $102.50 in the other case. These, of course, are not all of the factors to be considered; they are the principal ones, however, and this rough comparison indicates that conditions would have to be extremely favorable to the high-voltage lamp in order to justify its use to the exclusion of the lower-voltage lamp. If the cost of the copper in the neutral conductors were very much higher per lamp of load, if the cost of the balancing apparatus were greatly above that assumed above, relatively, and if the operating cost were lower, then there might be a better prospect for the 220-volt lamp.

There is no doubt that many three-wire plants find the 220-volt lamp very convenient for use in outlying and scattered districts where the load is not large and the cost of the neutral conductors would be disproportionate. This class of load does not constitute a sufficiently large percentage of the total station load to affect the cost of current supply appreciably. We are more and more firmly convinced, however, that the solution of the problem of low-potential distribution lies, not in the abolition of the three-wire system nor in jumping from 110 or 115 volts at the lamps to twice that e.m.f., but in raising the wire-to-wire voltage to the point where the over-all voltage of a three-wire system will be the limit allowed by the Underwriters, namely, 300 volts; 150-volt lamps are more practical than 220-volt lamps, and the former voltage is much more manageable in small devices, such as lamp sockets, receptacles, etc.

Electricity in the Drafting Room.

Even in industrial establishments and engineering offices where special efforts are made to increase the efficiency of the drafting force, it is doubtful that the full convenience of applied electricity is always realized. It is not uncommon to find in such places lighting arrangements which are not favorable to the most ordinary work, and which make it impossible to turn out, with any degree of comfort and speed, work of especial accuracy. Again, the chief draftsman's desk is not always provided with a telephone in establishments having an intercommunicating or private branch exchange switchboard system, and valuable time is wasted in going to and from the telephone. Many other apparently unimportant but really serious short-comings can be picked out in most drafting departments if one but takes the time and trouble to analyze the conditions carefully.

While very good general illumination has been secured by means of inverted arc lamps and white ceilings and walls, it is doubtful if anything is more satisfactory than individual incandescent or Nernst lamps intelligently disposed. Ceiling or wall clusters are of no use whatever beyond general illumination, enabling one to walk through the room without collision with a table or chair and to locate drawing cases, etc. For the actual inspection of drawings or prints in their files, a hand lamp on a flexible cord is much superior to any kind of fixture, and will usually make it possible to look over drawings without removing them from the cases. Another great convenience is a "bung-hole" lamp mounted beneath a glass drawing board to facilitate tracing a faint or weather-beaten original or other drawing.

Electric blue-printing apparatus is deservedly coming into wide use in drafting rooms where the output is large. The advantages of this class of apparatus are conspicuous. They render one independent of fickle weather conditions, and eliminate the pent-house, which usually exposes valuable tracings to the dangers of tearing and soiling on windy days and serious damage when rain comes up suddenly. Several hundred blue-prints per day can be run off on a machine of the type mentioned, and all with a degree of certainty and cleanliness which the ordinary sunlight method cannot approach. For drying and smoothing blue-prints, an electric flatiron is excellent, but it should not be applied directly to the print, of course.

Still another convenience, in establishments where photographing is done in the drafting department, is an electrically-lighted dark room, the lamp being an ordinary one mounted outside a ruby or orange-colored window in the wall of the dark room; whenever the natural light available through the window from the drafting room is sufficient, the special dark room lamp, of course, need not be lighted. For drying newly-developed plates, a small fan-motor is extremely useful, and will usually save from 85 per cent. to 90 per cent. of the time required for drying in still air.

Last, but far from least, efficient ventilation of a drafting room is best secured by means of motor-driven fans—not the ordinary fan-motor of the "buzz" propeller type, but fans built especially for ventilating purposes and intelligently installed. Drafting is arduous work, and good ventilation is as important to the efficiency of the men engaged in it as any other factor, excepting good illumination. Other improvements by means of electrical facilities will readily suggest themselves to any chief draftsman who chooses to consider the question seriously and in detail.

DESIGN AND CONSTRUCTION OF SMALL DYNAMOS AND MOTORS.

BY CECIL P. POOLE.

After completing the "laying-out" of the armature and its winding, the commutator and brushes, the amateur builder may pass on to the field magnet and winding. Tables VIII and IX gave the dimensions which

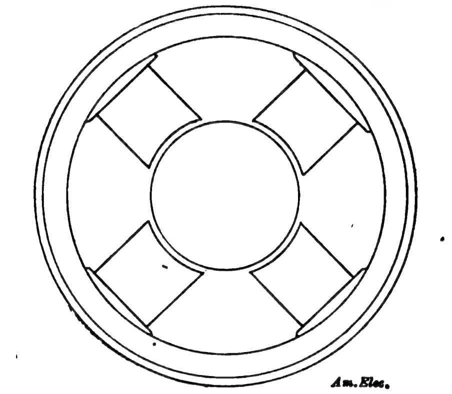

FIG. 7.

affect the electrical and magnetic features of the machine. The complete field magnet should be worked out before taking up the winding. Fig. 7 represents the familiar "circular-yoke" type of frame which is so much used now. On account of its conventional character, the builder may prefer to

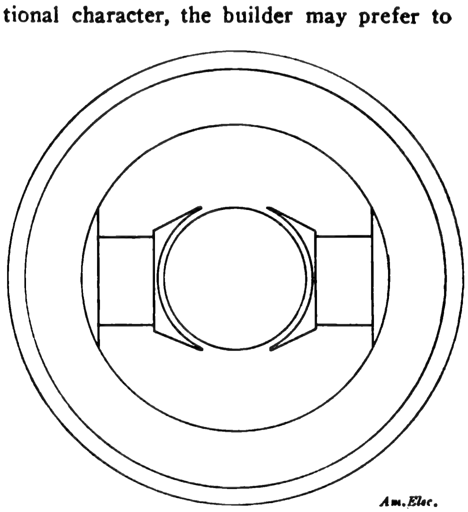

FIG. 7-A.

use it, but the writer prefers the less graceful shape shown by Fig. 8 for machines smaller than 8 inches polar bore. Figs. 7-A and 8-A show the bipolar frames corresponding respectively to the four-pole frames of Figs. 7 and 8. It is not intended that the shapes of magnet core shown shall be considered as belonging to these forms of

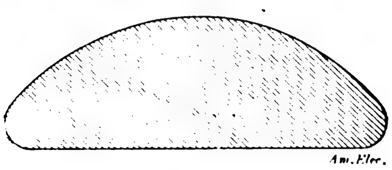

FIG. 9.

frame; they are only conventional, being shown merely to indicate the number of poles. If the circular yoke is used, then "pads" must be cast on the inside of the yoke to give flat surfaces for the seating of the magnet cores in those machines having cast-iron yokes and steel magnet cores, or to back up the coils of machines having the yoke and cores cast in one piece of iron or steel. These are shown in Figs. 7 and 7-a.

The width of the yoke parallel to the shaft should, if practicable, be sufficient to cover the magnet coils completely; if cast-iron is used, this can be done in all cases, but if the yoke of a multipolar machine is of cast steel, it will usually be too thin in

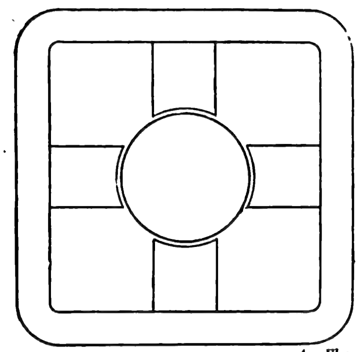

FIG. 8.

the direction at right angles to the shaft if it is made wide enough to cover the magnet coils. For cast-steel yokes, therefore, it is advisable to follow the rule of making the yoke thickness not less than ⅛ the axial width for circular yokes or ⅙ the axial width for other shapes. This will be accomplished by observing Rule XV. The yoke cross-section must be slightly thinner at the edges than in the center in order to facilitate casting it, and the machine will have a much better appearance if the dif-

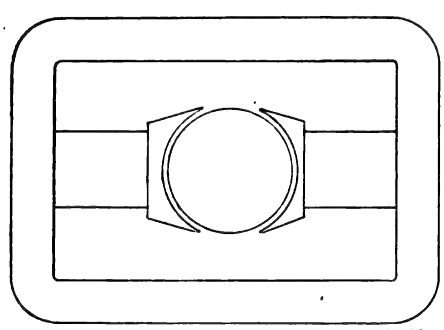

FIG. 8-A.

ference is something like 1½ or 2½ to 1; that is, if the yoke is 1½ or 2½ times as thick in the center as it is at the edges, as indicated by Figs. 9 and 10.

Fig. 9 represents the preferable shape of yoke cross-section to be used on a machine of the "box" type and also in circular machines having the journal boxes mounted

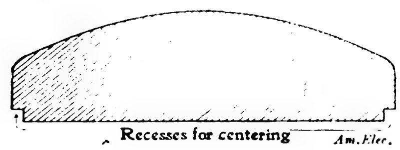

FIG. 10.

in vertical pedestals seated on projecting feet at the bottom of the frame, or on a base, as in Fig. 11. For machines having circular journal brackets, as in Fig. 12, the edges of the yoke must be thick enough to give a good bearing to the journal bracket ring and to take the bolts holding the ring in place; in such cases, the edges of the yoke ring must be machined flat, of course, and it will be found advantageous to tool out a slight recess, for centering the bracket ring, as indicated in Fig. 10. This will affect the relation between the yoke thickness at the edges and that at the center somewhat, but it will always be found practicable to "swell" the cross-section from the edges toward the center to some extent. The thickness mentioned in Rule XV is the *average* thickness, or one-half the sum of the edge and center thicknesses.

As the depth of the armature coil slots,

FIG. 11.

and therefore the length of the core teeth, cannot be fixed for each diameter of armature, it is impracticable to prescribe the field windings for the different diameters. The only way by which the builder can avoid the labor of calculating the field winding, which would be a tedious process neces-

sitating a knowledge of the most difficult part of dynamo designing, is to wind test coils for his machine and vary the field excitation until the desired e.m.f. of a dynamo, or speed of a motor, is obtained; then determine the permanent winding from the data derived from this test. Table X gives the proper size of wire to be used in

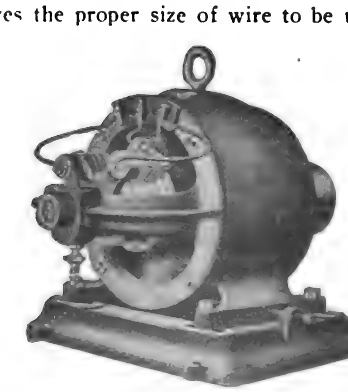

FIG. 12.

the test coils for different thicknesses and lengths of coil; the test coils should be wound to fill exactly the space that will be occupied by the permanent coils. Rule XVI gives appropriate proportions for field

magnet-coils. The determination of the size of wire for the permanent winding is as follows:

Connect the test winding to a 110-volt or 125-volt circuit in series with a small water rheostat, through a double-pole knife switch, with the rheostat adjusted to its highest resistance; drive the armature by belt at its rated speed if a dynamo; if a motor, drive it at 1.05 times its rated speed. Connect one terminal of a voltmeter to one of the terminals of the test winding and one of the commutator brushes of the machine; connect the other voltmeter terminal to a double-throw switch so that it can be connected to either the other terminal of the test winding or the other commutator brush, as indicated by Fig. 13. Start the test with the voltmeter connected to the brushes and proceed as follows:

Shunt-wound Dynamo.—Reduce the resistance of the water rheostat until the armature gives its full rated voltage with full load on it and running at rated speed. Switch the voltmeter over to the test winding and take the voltage at its terminals. Find in Table XI the column at the head of which is the size of wire that is in the test winding; trace down this column until the nearest larger number to the number of volts at the test winding is found; trace to the right along this line to the number in the column headed by the voltage of the machine; this last number will be the size of wire to be used in the permanent field winding.

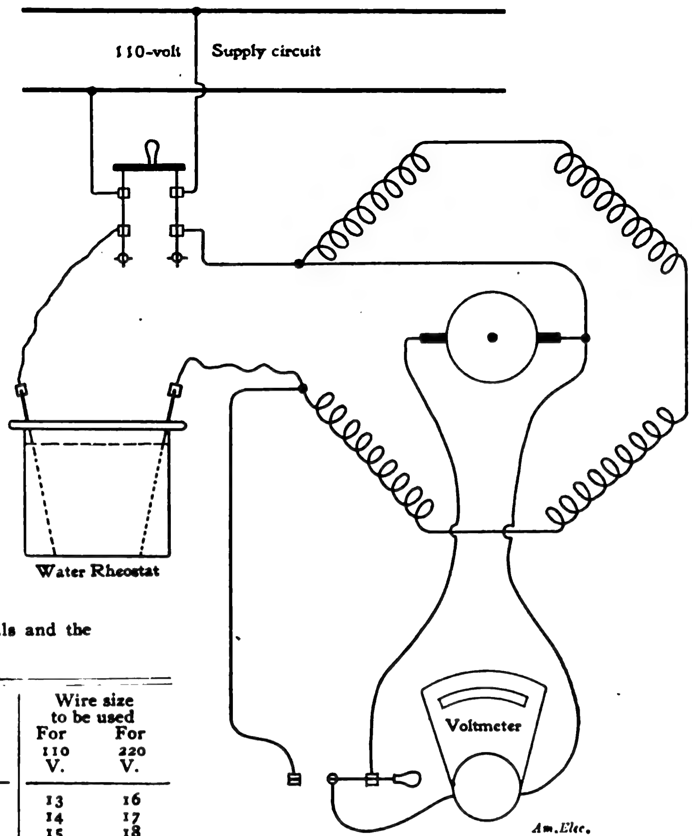

FIG. 13.

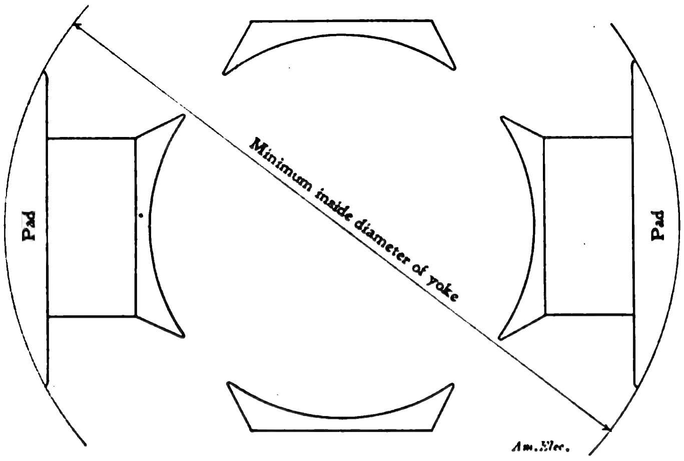

FIG. 14.

Rules.

Rule XV.—To ascertain the minimum thickness for a steel field magnet yoke, divide the cross-sectional area (Table IX) by 6, for a box yoke, or by 8, for a circular yoke, and take the square root of the result. If this does not give a practical working dimension, take the nearest larger practical dimension.

Rule XVI.—The thickness of each field magnet coil of a shunt-wound machine must be equal to not less than one-half of its length along the core and not more than the whole length.

The length of each field magnet shunt coil of a compound-wound dynamo must be equal to not less than 2/3 nor more than 3/4 of the total coil space along the magnet core.

The thickness of each field magnet coil of a compound-wound dynamo should be equal to 2/3 of the total coil space along the core.

Compound-wound Dynamo.—Proceed as before, except that the armature must be run without any load.

Shunt-wound Motor.—Proceed as before, except that the armature must be driven (by belt as a dynamo) at 1.05 times its rated speed and without any load.

If a direct-reading speed-indicator is available, the motor test may be made by running the armature free, as a motor, from a circuit of the proper voltage, adjusting the water rheostat until it runs at the proper speed and then taking the voltage at the terminals of the test winding. This, however, is much more difficult to carry out accurately than the dynamo test.

TABLE XII.—Field Magnet Series Windings.
The current specified in the table is the maximum that is allowable in series magnet coils.

6	17	12	4
7	13	13	3
8	11	14	2½
9	8½	15	2

The size of wire to be used in the series winding of a compound-wound machine may be obtained from Table XII. These sizes are empirical and it may be found necessary to use a "shunt strip" across the terminals of the series winding after the machine is finished. This can be easily determined by running the machine without load and with the field rheostat adjusted to obtain the proper voltage at the brushes, and then putting on full load without changing the rheostat and maintaining the speed constant. If the voltage at the brushes is excessive at full load, the series winding must be shunted until the proper voltage is obtained. If it is too low, the speed of the machine must be increased until the desired voltages are obtained at no load and full load, and this speed must be taken as the running speed of the machine. At each change of speed, the field rheostat must be adjusted to get the proper no-load voltage and left unchanged for the corresponding full-load trial.

The following example will serve to make the application of the rules and instructions in the present article clearer: Suppose a 4-pole machine has been built of the circular yoke type with a 10-inch polar bore and magnet cores of circular cross-section. From Table IX, the necessary cross-section for each magnet core (of steel) is 15¾ square inches, and from any table of circle diameters and areas it will be found that the core must be 4½ inches in diameter to have the required cross-section. The length of the coil space along the core must be 2⅛ inches. The machine is to be a compound-wound dynamo, to give 110 volts at no load and 120 volts at full load. From Rule XVI, the coils should be ⅔ of 2⅛, or about 1 7/16 inches, thick; it is not necessary to split hairs here, so the thickness may as well be made 1½ inches. The outside diameter of each coil, therefore, will be a trifle over 7½ inches (core diameter 4.5 + slight clearance + twice coil thickness) and the "pad" on the inside of the yoke ring must be at least that large, say 7¾ inches in diameter. By laying out the armature circle and magnet cores as indicated in Fig. 14, the inside diameter of the yoke ring is immediately obtained.

The yoke, if of cast iron, must have 21 square inches of cross-section. In order to cover the magnet coil satisfactorily it must be 8 inches wide, at least; the average thickness must then be $21 \div 8 = 2⅝$ inches, and this will be obtained if the edges be made 2 inches and the center 3¼ inches thick, or 1¾ and 3½ inches respectively. If a steel yoke is to be used, the cross-sectional area must be 0.4×21, or 8.4 square inches. From Rule XV, the average thickness must be at least

$$\sqrt{⅛ \textit{ of cross-section}},$$

which is 1.025 inches; if the edges be made ¾-inch thick and the center 1⅜ inches, the average will be 1 1/16 inches and the necessary width $8.4 \div 1.0625 = 7.905$ inches; 8 inches, of course, would be taken for the width.

If the rated speed is, for example, 1000 r.p.m., the machine should be belt-driven at that speed for the excitation test. The shunt coils will be 1½ inches thick and 1½ inches long, and the test coils should have these dimensions; from Table X, No. 18 wire should be used in the test coils. Suppose that at no load the voltage required at the terminals of the test field winding to produce 110 volts at the brushes is 81 volts. In Table XI, for 110-220-volt machines, in the column headed by No. 18 is found 70.4 and 89.1, between which the test voltage lies; take the larger value, 89.1, and trace to the right along that line until the number in the 110-volt column is reached; this is 19, which is the size of wire to be used in the permanent winding. (Just here, the writer would advise that when the permanent wire size comes so near to the test wire size the builder may as well retain the test coils instead of making new ones. The test coils should be well insulated in the winding, with this in view. If they are of wire one size too large the rheostat will need to be of higher resistance than normal, to reduce the shunt current sufficiently; if they are of wire one size too small, increase the speed of the machine to get the desired results.)

The use of Table XII requires no explanation; correction for faulty compounding may, however. Suppose that the machine, complete with its shunt and series windings, gives 110 volts at no load and 112 at full load. Take off the load, set the field rheostat *back* two or three segments (in the direction to decrease the voltage) and speed the machine up until it gives 110 volts without load. Then put on full load and measure the voltage; if it is still under 120, repeat the correction; if it is above, set the rheostat *forward* one segment and reduce the speed until 110 volts at no load is obtained and try the full-load voltage. By successive trials a point can be reached at which proper compounding is obtained. If the machine over compounds at the speed for which it was designed, the speed should not be changed, but the series winding shunted to give the desired results.

PUMPS IN CENTRAL STATIONS.

BY W. T. EDWARDS.

The delivery pipe of pumps may be smaller than the suction pipe; in fact, it need not be more than one-half the area, the velocity of the water being about 400 feet per minute. A check valve should be placed in the delivery pipe and connected directly to the delivery flange of the pump if practical. It should always be straight away, and fitted with hinged or swinging valves. The diameter should always be equal to that of the delivery opening of the pumps.

The loss due to elbows and valves is not a fixed value, and varies according to the conditions of the fittings and the velocity of the water. An approximate rule is to consider the loss in each elbow equal to the loss in a straight pipe, whose length is 60 times the diameter of the elbow, and the loss due to a globe valve equal to the loss in a straight pipe having a length equal to 90 diameters. It is better that all valves used throughout a system should be of the gate type. As the friction of water flowing through pipes, passages, etc., increases as the square of the velocity, it is advisable to keep the velocity as low as possible without making the pipes or pump unreasonably large for a given capacity.

A pump should discharge in a smooth, continuous stream, and in order to secure this, air chambers are placed on the highest point of the delivery chambers. The function performed by the air chamber is that of a cushion to relieve the pump and piping system of shocks or jars due to the intermittent discharge of the pump.

Duplex pumps have a more uniform flow than single-acting pumps, and consequently require a much smaller air chamber; the largest size being used for the single-acting and the smallest size for double-acting duplex pumps.

The vacuum chamber is usually placed so as to receive the full impact of the water in the suction pipe. Its purpose is about the reverse of the air chamber inasmuch as it changes a continuous flow into an intermittent one. Water passing into a pump under atmospheric pressure does so in a continuous stream, and the movement of the pistons causes this water to be received into the pump cylinder intermittently. This interrupted column of water would result in water hammer and other disturbing influences on the pump were it not for the air in the vacuum chamber, which forms an elastic cushion, which receives the excess of flow without noise and gives it out as silently as it receives it. It is not a vacuum chamber, but an air chamber, for there is no such thing as a vacuum chamber connected with a pump.

In all cases where a pump has to take its supply by suction it will be found convenient to provide a priming pipe and a relief pipe both fitted with suitable valves. The priming pipe may be connected to the pump cylinders or to the suction chamber of the pump if there be a foot valve provided in the suction pipe. The priming

pipe may get its supply from a tank, or it may be tapped into the discharge pipe from the pressure side of the check valve. By opening the valve in the priming pipe, water from the tank or reservoir is allowed to fill the pump and suction pipe, while the valve in the relief pipe is opened to allow the air to escape. The relief pipe should be lead to a drain or to any place where it will not cause inconvenience. Centrifugal pumps are sometimes primed by a small hand pump located on the side of the shell, an air cock at the top being opened and the hand pump used until water flows from the air cock. A steam ejector is sometimes used for the same purpose, the passage of the steam forcing the air out of the pump and suction pipe on the same principle that the steam in an injector lifts water and forces it into a boiler. While the priming is being done it is usual to shut off the delivery pipe by closing a gate valve, opening this gradually as the pump comes up to speed. A temporary expedient is to blank off the discharge pipe with a piece of plank held tight against it.

If it is practicable, a pump should be placed on its foundation so that it will be at a convenient height for a man to work around it without stooping. A drip pan should be placed upon the foundation under the pump between the supports or bearings. These pans should be loose, so that they can be removed for emptying. It is a mistake to fasten them to the foundation even though they be provided with a faucet or cock for draining, as the pans will rarely drain clear of themselves, and consequently the water has to be mopped out.

As to which is more economical, the power-driven pump or the direct-acting steam pump, much is said on both sides.

The statement is frequently made without qualification that power-driven pumps are more economical than steam pumps. This may be true under certain conditions, while under other conditions the reverse is the case. With a non-condensing engine where all the exhaust steam is passed through a primary feed-water heater and wasted, other conditions being equal, the power pump is the most economical; but when engines are operated condensing and the exhaust from the pumps is used for heating the feed-water, the steam pump shows up well for economy. However, it is not within the province of this article to enter upon a discussion of the relative efficiencies of the two methods of driving pumps. Under the present approved practice of operating engines condensing, the use of the direct-acting steam-driven pump, utilizing the heat in the exhaust steam for heating the boiler feed-water, is along the lines of best economy. An objection to the use of power pumps is their lack of flexibility. They usually run at a uniform speed, and any excess of water must be wasted through a relief valve, or the boiler filled and the pump stopped until the lowering of the water in the boiler makes it necessary that the pump be started again.

MOTOR-BALANCERS FOR THREE-WIRE SYSTEMS.

BY FRANCIS W. APPLETON.

In stations where it is impracticable to get along with only one pair of dynamos, one on each side of the neutral, it has been invariably found advantageous to use main generators giving the full voltage required between the outside wires of the system and to employ auxiliary means for "balancing" the system, or more correctly, for maintaining the proper voltage on both sides of the neutral despite unsymmetrical variations of the load. One of the simplest means for this latter purpose is the motor-balancer, consisting merely of two dynamo-electric machines exactly alike, each wound for the voltage between the neutral and the outer wires, and having their shafts rigidly coupled. These machines are connected to the distribution circuits as indicated by Fig. 1, and the neutral feeder is not connected to the main dynamo at all.

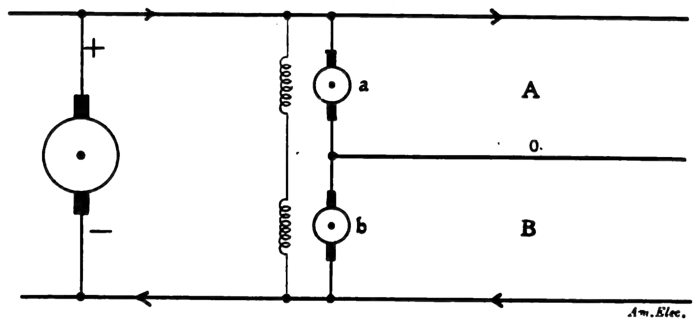

FIG. 1.

So long as the load is balanced, that is, equal on both sides of the neutral feeder, the two machines run as motors. Now, if part of the load on the "A" side of the neutral be thrown off, there will flow in the neutral feeder a current equal to the difference between the currents required by the loads on each side of it; the voltage between the neutral and the positive feeder will be momentarily higher than that between the neutral and the negative feeder because of the difference between the drop in the two outer feeders. Consequently the armature *a* will increase its speed, carrying with it the armature *b*, the counter e.m.f. of which now exceeds the voltage of its half of the system and therefore raises the voltage of that half to a value nearer that of the other side. The current in the neutral feeder will divide almost equally between the armatures *a* and *b*. If the balancer armatures could have no resistance whatever and required no power to drive them, the division would be absolutely equal. This ideal condition is indicated diagrammatically in Fig. 2, where it is assumed that the load in the "A" side is 90 amperes and that in the "B" side 100 amperes. Ignoring losses in the balancer, the motor half, *a*, will require as many amperes to drive the dynamo half, *b*, as that armature delivers to the line, the voltages of the two (assuming temporarily no losses) being equal after the division of the neutral current between them. Therefore, 5 amperes of the 95 supplied by the main generator passes through the armature *a* to the neutral wire, enabling that armature to drive the armature *b* at such a speed that its excess in voltage over the line voltage causes it to supply 5 more amperes, which join the 5 amperes of motor current at the neutral junction, making 10 amperes in the neutral feeder. The motor-balancer, therefore, only needs to have a current-carrying capacity equal to one-half of the current in the neutral feeder under the worst load conditions.

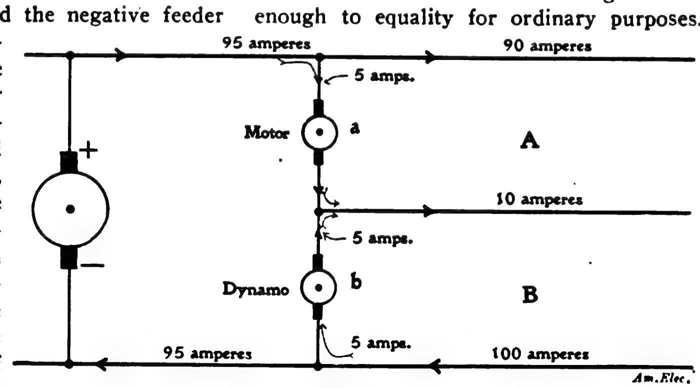

FIG. 2.

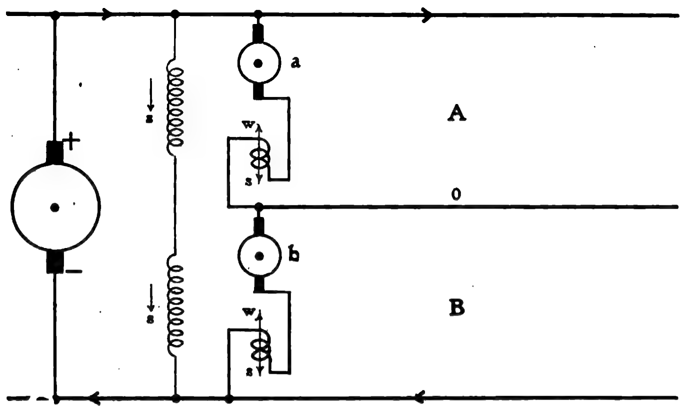
In practice, the neutral current is not divided equally between the two balancer armatures because of the losses in them. The armature which acts as a motor must receive more current than the current delivered by the dynamo half of the pair. But inasmuch as the voltage is not maintained exactly equal on both sides of the neutral, the departure from equality of current division is less than would appear. On account of the drop in the armatures, the motor half must be supplied with an e.m.f. greater than that delivered by the dynamo half, both of them running at the same speed and with equal field strengths. The difference between the two voltages, also, is increased by the unequal division of current between the armatures; the current in the motor half being greater than that in the dynamo half, the drop is greater. However, machines of very low armature resistance will maintain the voltages near enough to equality for ordinary purposes.

In order to make the equalization perfect, the balancer machines are frequently compound-wound, the series windings being so connected that the machine taking current as a motor will have its field weakened by the series winding while its mate, the dynamo, will have its field strengthened by the current passing through it. Such an arrangement is indicated diagrammatically by Fig. 3, which shows a balanced lead con-

dition. If the load be decreased in "A" or increased in "B," current will flow toward the neutral through both armatures and series field windings, weakening the field of *a* and strengthening that of *b*. If the load be greater in "A" than in "B," current will flow *from* the neutral through the two ar-

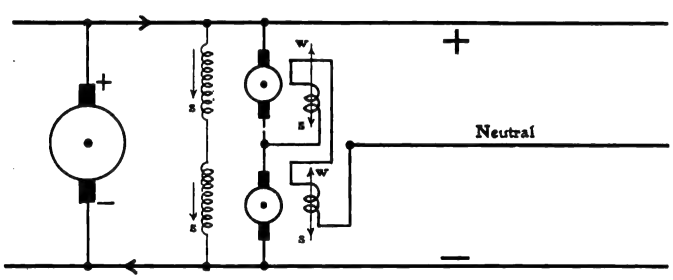


Current in the direction s strengthens the field; current in the direction w weakens it.

FIG. 3.

matures; *b* then running as a motor, with a weakened field, and driving *a* as a dynamo with a strengthened field, the current through both being opposite to its direction in the other case of unbalancing.

With the arrangement shown in Fig. 3 the effects of the series windings of the balancer machines will be unequal because the



The double arrows s ⟷ w refer to currents in the series field coils.

FIG. 4.

currents in the two machines are unequal, as already explained. Fig. 4 shows an arrangement for correcting this disadvantage which was described to the writer several years ago by the editor of the AMERICAN ELECTRICIAN. Here, the series windings are

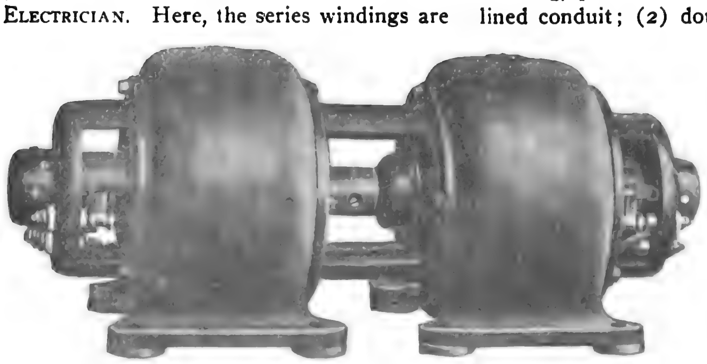


FIG. 5.—MOTOR BALANCER

connected oppositely in the neutral lead from the machines; consequently the weakening and strengthening effects are exactly equal because the same current flows through both windings.

THE WEAKEST POINT IN AN ELECTRICAL SYSTEM.

BY ELMER E. WARNER.

From the practical point of view a laboratory insulation test on an electrical appliance is no more determinative of its safety than the sign "harmless" above the kennel of a sleeping bulldog.

Every experienced electrician knows that there are two factors which chiefly fix the risk in every part of an electric system; namely, (1) the working conditions under which the appliance is installed and used, and (2) the element of deterioration. If a factor of safety could be deduced which would cover the additional risk due to the special conditions under which the appliance is used, such as dampness, inaccessibility, excessively warm location, liability to mechanical injury, etc., and another which would represent the yearly decrease in efficiency or deterioration toward the safety limit, one could determine within reasonable bounds what the initial standard should be.

Thus, instead of requiring a common insulation test a minmum should be fixed for the most favorable conditions in common practice and percentages added for, say, the two additional classes of higher risk.

Taking the primary or factory insulation of ordinary copper wire as a fundamental illustration, there are: (1) Single-braided wire with a secondary insulation of wood molding, porcelain cleats, circular loom, or lined conduit; (2) double-braided wire, the additional braid giving the added percentage of insulation necessary to protect the wire from mechanical injury in fishing through conduits or where exposed as ordinary portables; (3) a triple-braid or steel armor used with no secondary insulation, and where wires are exposed to great mechanical strains and wear, such as portables around engine and fire rooms and in buildings under construction, etc. Giving as great an increase in insulation as practical for these portable extensions of the system, one must still add a much greater percentage for deterioration. Where a single-braided wire in molding may be safe for ten years, a portable may not be for one.

The greater risk to the flexible cord dangling in the air and frequently hung over gas pipe and twisted around nails or wood projections is clearly recognized by the underwriters in the demand for an extra covering or reinforcement. The element of human depravity, of carelessness and mischievousness enters here as a large item in the risk. The writer recalls one embryo electrician in particular whose chief delight it was to short-circuit a testing line and blow the fuses when some unsuspecting companion was working near the block.

This greater risk in the more exposed parts of the system is slightly reduced by the fact that such parts and places are under direct observation, but it still remains the weakest part of the system and fixes the period between inspections.

Inspection to be of the greatest value should cover the weakest point in the system and that, as collected data show, is not in new work under the latest rules, but old work which was done before rules were formulated or respected.

The most frequent violations are as follows:

Open-link fuses or fuse wire, or fuses of solid copper or fuse wire too heavy to protect circuit from dangerous overheating.

Flexible cord twisted around metal supports, particularly gas fixtures and grounds. Flexible run on ceilings or sidewalls in place of fixed wiring. Joints in flexible cord generally unsoldered.

Unsoldered joints in circuit wiring and partial breaks and defective insulation, particularly behind old fixtures and in damp locations, such as basements, toilet rooms, etc.

Crepe paper or inflammable draperies in contact with incandescent lamps.

ARMATURE TESTS IN REPAIR SHOPS.

BY ARTHUR B. WEEKS.

Not every armature winder has a room in which to carry on his work; should this be the case, strike off a partition somewhere, running a trolley tap into the improvised room, as shown in the accompanying sketch. The wire should be run through a porcelain tube where it passes through the partition wall, and be anchored to an insulator at the further side of the room.

Next fasten a fuse block to the wall, making up a wooden support for this and for the switch and rheostat, should the side of the building be of corrugated iron. Should there be no rheostat to spare, rig up a tank or barrel for this purpose, locating it in a pit below the floor line, should there be such a pit available.

Place the armature to be tested on a support as shown, and on a nearby table a direct-current ammeter of 0 to 150 amperes capacity, and a voltmeter of 0 to 600 volts on one scale, and 0 to 10 on the other.

Make connections as shown. A support is necessary for the brush holder yoke, so that it may occupy the same relative position as in the motor. This is shown in Figs. 1 and 2. Fasten it to the "horse" with wood screws. Use the holes in the brush holder yoke for its support. Allow clearance between the armature shaft and the support, if made of iron; otherwise the readings will be misleading.

Before testing it is necessary to say more about the voltmeter. A regular meter reading 0 to 550 or 600 is entirely satisfactory for some tests, but is not sensitive enough between 0 and 5 for testing bar to bar on the commutator, one from 0 to 10 on a second scale being best adapted for this purpose. There are three binding posts, one for a common connection, one for the 600 scale, and the other for 10 scale. Do not make a mistake in the binding posts when testing.

Everything being ready, with brushes ground to a good fit, close the switch and turn on the rheostat until a current of about 40 to 50 amperes passes; the rheostat will stand this for some time. Now, suppose the armature has been completely rewound, and one desires to know if there are any cross connections, or if short-circuits exist in the commutator or coils. With the voltmeter connected for the low reading scale, make contact, bar to bar, pushing the armature over a little at a time, to reach each of the bars in turn. Begin on either side, as most convenient. If everything is normal, the reading will be anywhere from 1 to 4 volts, depending upon the character of the winding and the points where the voltmeter is applied to the commutator. If the voltmeter shows zero, there is a short-circuit. This is usually caused by solder having run down the back of the commutator when soldering in the leads, and by this test it may be located and removed in a few moments. Use a scratch awl for removing the solder.

To test for a grounded armature, which should perhaps be the first test made, since the above test made on a grounded armature might seriously injure the insulation, the ammeter is not required at all. Disconnect the lower wire from the rheostat and armature, and take out the brushes, connect as in Fig. 3, and touch the commutator with the free end, *C*. Whatever

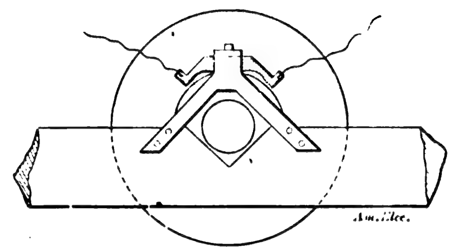

FIG. 2.

reading there is shows leakage. Touch the free end, *C*, on the armature shaft and the full line voltage is obtained.

If a ground exists, disconnect the leads of the coils from the commutator bars affected, and further probing may trace the trouble to a coil grounded on the core in its slot, or it may be the commutator is grounded. If the grounded armature has been just taken out of service, the chances are that the commutator will show by discoloration the part affected.

Before testing from bar to bar for any fault, it is a good plan to sandpaper the entire commutator thoroughly. On any railway motor commutator that has been used at all, one can get a ring with a magneto from bar to bar all around it after it has been entirely disconnected, or if five lamps in series are used for testing, they will light up. In most cases this is caused by carbon dust, though in some cases it has been traced to a too free use of fluid acid flux. The writer recalls a case where a commutator of a 500-h.p. machine had its mica insulation ruined by the too lavish use of fluid flux which attacked the copper to such an extent that the commutator required an entire dismantling, the bars cleaned, and new mica segments inserted. All manner of schemes were first tried for correcting the trouble, but without avail. The motor was tried with current, after having been first connected, but the commutator grounded on the inside and burned a great hole before the machine was pulled off the line.

There are easy formulas used in connection with these meter tests, which can be easily worked out by anyone. Take, for example, the ground test, where the voltmeter is in series with the armature. If one has never connected a meter in this way and is not familiar with testing instruments, he may have an idea that the current may burn it out. This is erroneous, as the resistance of the voltmeter is very high, about 80,000 ohms, and prevents any rush of current.

It is best to test electric apparatus when warm. If a commutator has been repaired and fresh shellac or varnish used in the segments, bake the moisture out either before or after the commutator is connected, and always test after baking. The use of the voltmeter in testing for faulty field coils gives one a sure test. It is a great saver of time and material; for without its use it is no uncommon thing to be compelled to tear out coils and dig into them one after another, before the right one is found. And often after all this expense, the coils have been found all right and the trouble located elsewhere. The proper instruments should, therefore, be provided for the careful testing of apparatus in every well regulated electric light or railway plant.

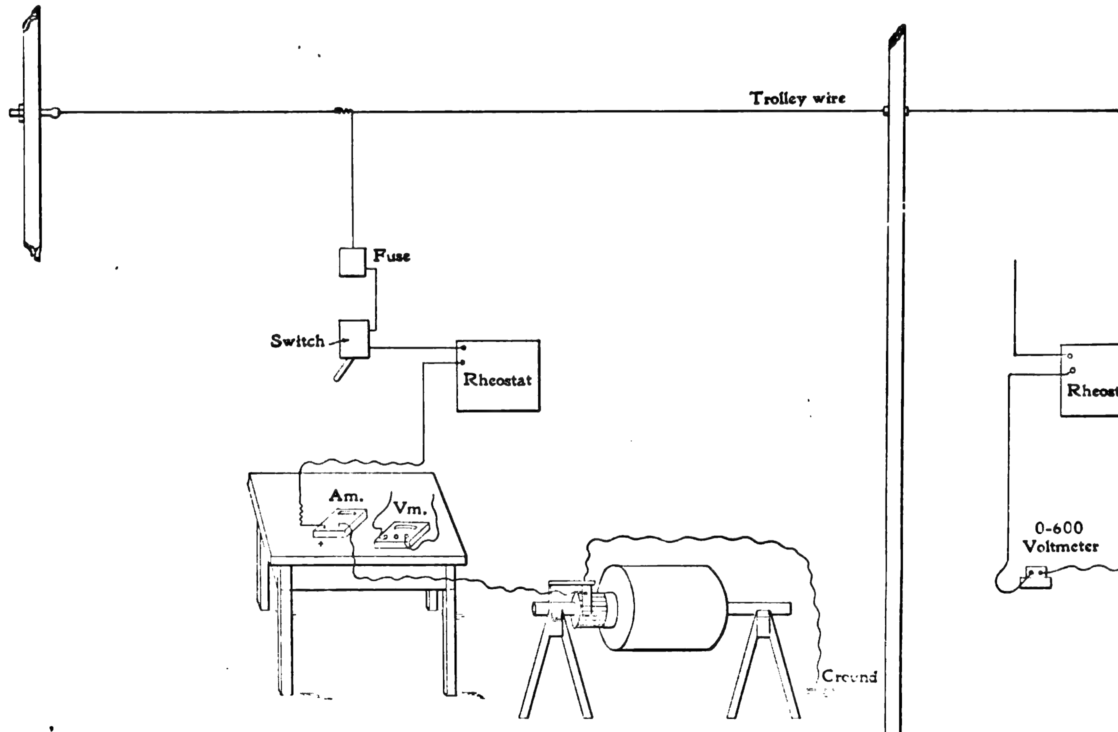

FIG. 1.

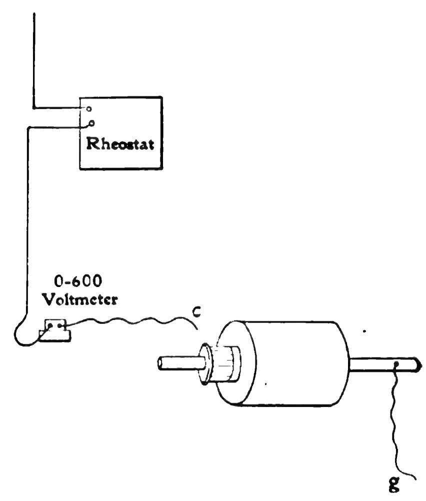

FIG. 3.

GROUNDING DISTRIBUTION SYSTEMS.

Although the grounding of secondary alternating-current circuits and the neutral feeders of three-wire systems is not positively required by the fire underwriters, it is generally conceded to be practically as important as though actually required. There is little doubt that such practice will ultimately be compulsory. Even if the fire risk be ignored, human safety requires that distribution circuits should be grounded in such manner as to minimize the difference of potential between other grounded objects and ungrounded parts of the circuits.

Three-wire systems should be thoroughly grounded at the neutral conductor in as many places as practicable. The neutral bus-bar on the station switchboard should be connected to the nearest water main; the neutral terminal of the entrance cut-out of every building should be similarly grounded, and it is a good plan also to connect the gas piping and any steam piping that may be in a building to the water piping, so that all foreign metallic systems with which persons can come into contact will be at the same potential as the neutral conductor of the electric lighting or power circuits. By this means the maximum possible voltage to which one can be subjected is the voltage between the neutral conductor and one of the outer conductors of the heavy current system. Should one of the main conductors become accidentally grounded, that conductor and the neutral conductor will be connected through the grounds and the fuses will, or should, blow. Even if at first the neutral fuse alone blows, the grounded main and the neutral feeder from the station will be short-circuited and the main fuse must blow immediately after the neutral fuse; as a matter of fact, the two will "go" so nearly simultaneously that the time difference is indistinguishable. This may be readily understood by reference to Fig. 1. Leaving out the question of fuses, however, if the neutral conductors throughout a system are well grounded, an accidental ground on either of the mains will put that main and the neutral conductor at equal potential (practically), and the maximum potential within reach of anyone will be that between the neutral conductor and the ungrounded main conductor. If the neutral is not grounded, an accidental ground on either of the main conductors will make it possible for anyone to receive the full over-all voltage of the system by touching an exposed terminal post or other device that is connected to the ungrounded main while standing in a wet spot or in contact with water piping.

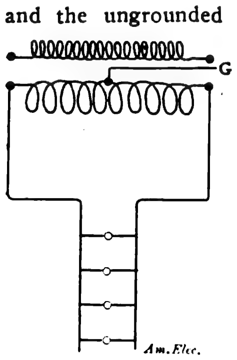

FIG. 2.

Secondary alternating-current systems should be grounded in much the same way as just described; if the distribution is on the three-wire plan, the neutral lug of the entrance cut-out should be grounded, but if two-wire distribution is used, the middle point of the transformer secondary winding should be grounded, as indicated in Fig. 2. With three-wire distribution, and a transformer on each side of the neutral, the middle point of the transformer secondary cannot be grounded because that would short-circuit all of that part of the secondary circuit between the central points

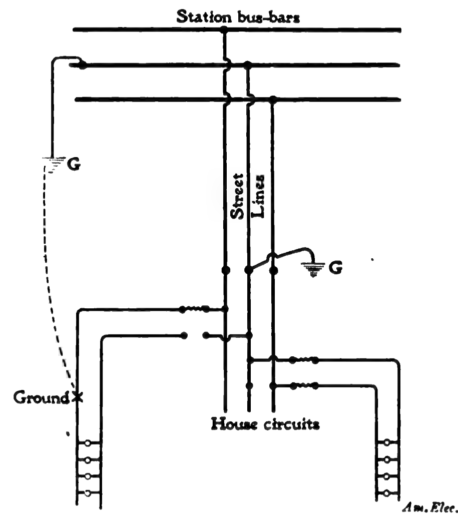

FIG. 1.

of the two transformers, as indicated in Fig. 3. The best plan is to use three-wire transformers and ground the middle terminal, when three-wire distribution is used.

When two-wire distribution is employed and it is impracticable to ground the middle point of the transformer secondary winding, one terminal of every transformer should be securely grounded so that in the event of a break-down of the insulation between the primary and secondary windings the primary circuit will be grounded; then if it is accidentally grounded elsewhere (the writer never saw a primary circuit actually free from ground leakage) either the fuses will blow or the secondary circuit voltage will not be raised. This will be evident from a consideration of Fig. 4; if the reader will mark any point on the primary circuit as being accidentally grounded so as to increase the potential between the secondary circuit and the ground, he will find that the accidental primary ground produces a short-circuit through at least one of the transformer primary fuses.

Transformer cases should invariably be thoroughly grounded; this increases the burden of the manufacturer and imposes upon workmen who have to make transformer connections the necessity of being extra cautious during the making of such connections. But it protects everyone, after connections have been made, from shock due to primary leakage and accidental contact with the transformer case.

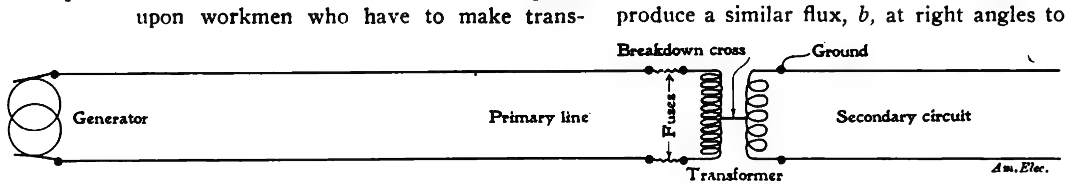

FIG. 4.

Principles of Electrical Apparatus

ACTION OF AN INDUCTION MOTOR ARMATURE OR ROTOR.

Two coils disposed at right angles on a single core, such as an armature core, and supplied independently with two alternating currents differing in phase by a quarter cycle, will produce a bipolar magnetic field that will rotate in a circle concentric with the core. Now, if the coils be mounted with a ring-shaped core, as in Fig. 1, the result will be precisely the same except that the magnetic poles will be manifested on the in-

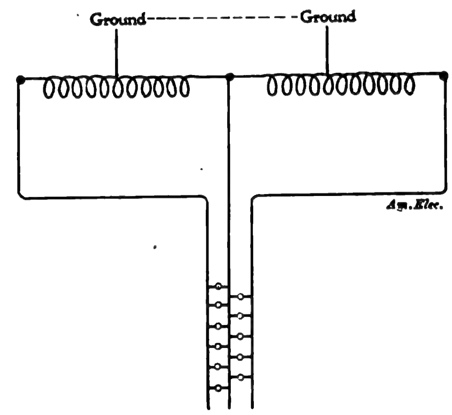

FIG. 3.—GROUNDING DISTRIBUTION SYSTEMS.

terior of the ring. Such an arrangement would be designated a bipolar field, because the two fields produced individually by the two windings combine in a single rotating field within the ring, whose axis is diametrical with regard to the hole in the ring. The construction indicated, however, is not practical; in order to allow the insertion and removal of an armature, each of the field coils must be divided into two, and the four resulting coils disposed somewhat as indi-

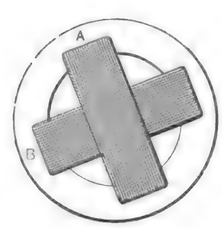

FIG. 1.

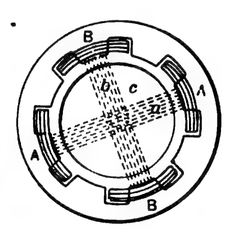

FIG. 2.

cated by Fig. 2, so that an armature core, *c*, may be inserted in the central hole.

In this event the two coils marked *A* assist each other in producing a flux, *a*, across the central core, and the coils marked *B* produce a similar flux, *b*, at right angles to this, the two combining in a single rotating field as before. Thus, with maximum current in *A* and *A*, the current of *B* and *B* will be zero and a flux will be produced as indicated in Fig. 3; when the current in *A* and *A* falls to 0.707 of its maximum, that in

B and *B* will have risen to exactly the same degree, and the resultant flux will occupy the position shown in Fig. 4. At the next eighth of a cycle the current in *A* and *A* is zero and that in *B* and *B* is maximum, locating the flux as shown in Fig. 5; and so on, through the complete cycle, as indicated by Figs. 6 to 11. In these diagrams for simplicity the flux is represented by only two dotted lines which indicate its general direction across the core and its division in the ring. With the elementary construction shown, there would be a leakage flux around the sides of the coils, as indicated in Fig. 11; for the present we must neglect this.

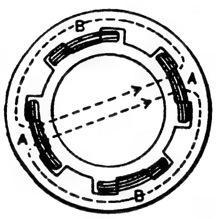

FIG. 3.

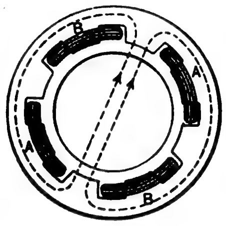

FIG. 4.

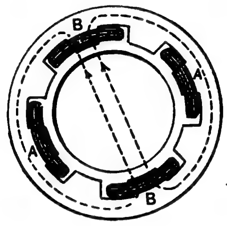

FIG. 5.

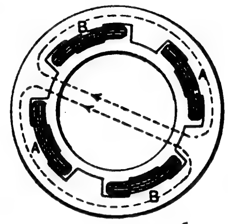

FIG. 6.

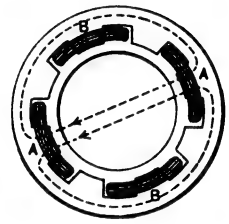

FIG. 7.

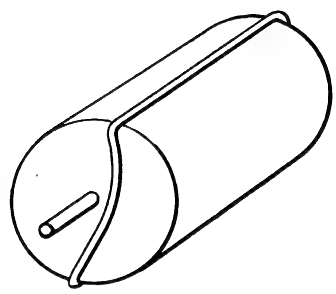

FIG. 12.

Now suppose a single turn of wire be wound on the drum core, as shown by Fig. 12, and the ends connected to form a closed circuit. If this core be inserted in the ring and held still while two-phase currents pass through the coils, the rotating field will be cut by the two wires on the drum every time it makes a revolution, and will induce in each side of the loop an e.m.f. equal to

$$e = \frac{2.22\ \Phi\ rps.}{100{,}000{,}000},$$

where *rps.* is the number of revolutions per second made by the flux and Φ is the number of magnetic lines passing through the drum. Consequently the total e.m.f. induced in the loop on the drum will be

$$E = \frac{44.4\ \Phi\ rps.}{100{,}000{,}000} \quad . \quad . \quad . \quad (1)$$

The e.m.f. thus induced causes a current to flow in the armature loop, the magnitude of which, ignoring self-induction, will be determined by Ohm's law. The e.m.f. and current in the loop will, of course, be alternating, because the direction of the flux is reversed at every half revolution. Now, if the current attained its maximum value at the instant when the sides of the loop had been swept by one-half of the flux, the flux would exert a dragging effort on the wires tending to rotate the drum with a force equal to

$$\frac{2\ I\ l\ \mathrm{B}}{11{,}303{,}000}\ lbs.;$$

the current being represented by *I*, the length of the drum in inches by *l*, and the density in magnetic lines per square inch in the air-gap by B. The numerator contains the figure 2 because there are two active conductors at the periphery of the drum. Armature reaction and self-induction in the armature winding, however, have the effect of reducing the torque to a value much smaller than this formula would make it. A general formula might therefore be written thus:

$$T = \frac{w\ i\ l\ \mathrm{B}\ k}{10{,}000{,}000} \quad . \quad . \quad . \quad (2)$$

in which *T* is the torque in pounds; *w* is the number of wires around the periphery; *i* is the current per wire; *l* is the length of the core; B is the magnetic density in the air-gap, and *k* is a number covering the effect of armature inductance and reaction and the change in the denominator.

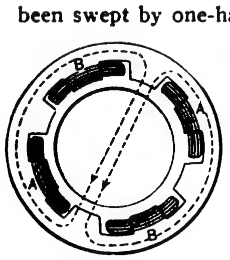

FIG. 8.

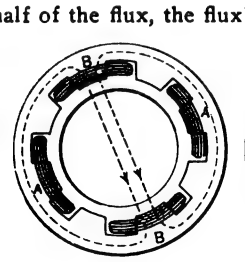

FIG. 9.

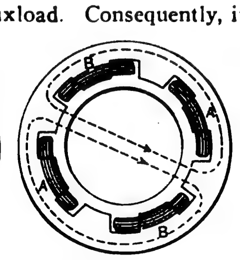

FIG. 10.

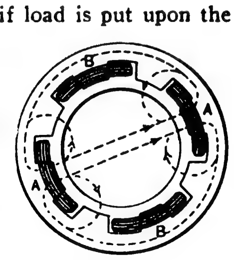

FIG. 11.

It is evident, however, that if the drum is left free to turn, the pull exerted by the rotating field upon the sides of the loop will drag the drum around. It will be also evident upon reflection that as soon as the drum begins to revolve, the wires on it will not cut so many lines of force per revolution as before, but will cut only a number proportional to the difference between its own speed and that of the rotating magnetism. Consequently, the e.m.f. induced in the armature loop will become less as its speed increases, and the armature current and torque will also become less; this will be clearer if the reader will consider that if the drum were driven by a belt at a speed equal to that of the magnetic field the sides of the loop would not be cutting any flux and there would be no e.m.f. induced in it. The operation of an induction motor, therefore, requires that the speed of its armature must be less than that of the rotating field by an amount sufficient to allow the armature conductors to cut the flux at a rate that will induce an e.m.f. in the conductors which will force enough current through them to give the requisite pull or torque to carry the load. Consequently, if load is put upon the armature, its speed will be reduced until the current flowing will be sufficient to give the required torque.

For example, still assuming the ideal condition of no lag by the armature current, and no armature reaction, if the speed at which the magnetic field rotates be 60 revolutions per second and the armature speed, running free, be 59.85 revolutions per second, the armature wires would cut 0.15 or 15 per cent of the total flux per second. Now, if the armature should have a load put upon it equal, say, to 20 times its friction load, the speed would be reduced until the wires would be cutting 20 times the number of lines of force previously cut; that is, the total flux would have to be cut $0.15 \times 20 = 3$ times per second. Consequently, the difference between the speed of the armature and that of the magnetic field would have to be 3 revolutions per second, which would bring the armature down to 57 revolutions. The difference between the armature speed and that of the rotating magnetic field is called the "slip," and it is usually written as a decimal but referred to as a percentage. Thus, in the case just mentioned, with the armature making 57 revolutions per second while the speed of the magnetic field is 60 revolutions, the difference of 3 revolutions per second is the slip, and its numerical value is $3/60 = 0.05$; it would be referred to as a slip of 5 per cent.

As stated in the beginning of this article, the resultant rotating field due to the combination of two (or more) alternating-current fields of different phases will have the same number of poles as each of the component fields. For example, in the elementary machine under consideration the flux set up by each pair of coils gives a bipolar field, and the two fluxes combined give a resultant rotating field which is also bipolar. Consequently, when one speaks of the number of poles on an induction motor it is always the number of poles *per phase* that is meant, which is equivalent to the number of poles of the resultant field formed by combining the two (or more) phases. The rotating magnetic field makes one revolution during each cycle of the magnetizing currents if the field is bipolar; the speed for more than two poles therefore would be

$$\frac{2\ f}{p} = rps. \quad . \quad . \quad . \quad (3)$$

in which *f* is the frequency of the supply current in cycles per second, and *p* is the number of poles.

As previously stated, the e.m.f. induced in the armature conductors will be alternating, and the frequency of this e.m.f. will vary inversely as the speed of the armature. The reason for this apparently contrary variation will be evident upon a little reflection. If the drum should be held stationary, the e.m.f. induced in the conductors by the rotating flux will have the same frequency as the supply current, but if the drum be driven by a belt at the same speed as the

flux there will be no e.m.f. induced because the wires will "cut" no magnetic lines of force, and the frequency will therefore be zero. The frequency of the e.m.f. in the armature conductors is given by the formula

$$f'' = f \times s \quad . \quad . \quad . \quad (4)$$

in which f'' is the frequency of the e.m.f. in the armature conductors, f is the frequency of the supply current, and s is the slip expressed in terms of the frequency. For example, an armature running at 57 *rps.* in a bipolar field produced by 60-cycle currents, would have a slip, as previously explained, of 0.05. The frequency of the current in the armature conductors, there-

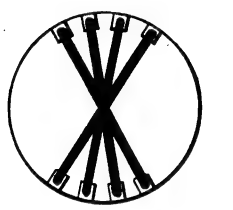

FIG. 13.

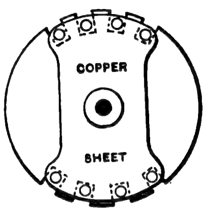

FIG. 14.

fore, would be $0.05 \times 60 = 3$ cycles per second.

Formula (2) shows that multiplying the number of conductors on the armature core will increase the pull or torque. Thus, a core wound with four loops as in Fig. 13, would have four times as many conductors on its surface as the one shown by Fig. 12, and the current would be the same in each conductor because every loop has the same e.m.f. induced in it and is of the same resistance. The torque, therefore, would be practically four times as great. It would make no difference whether the loops were kept separate or connected in series, or in parallel as in Fig. 14; the latter construction is the simplest.

As previously shown, the speed of the armature is nearly equal to that of the rotating field, lacking only the small amount represented by the slip, and the field speed, or synchronous speed as it is termed, is $\frac{2f}{p}$ revolutions per second or $\frac{120 f}{p}$ revolutions per minute. The frequency (f) ordinarily is 25, 30 or 60 cycles, so that a bipolar motor with a slip of 5 per cent would have an armature speed of 1425, 1710, or 3420 r.p.m., according to the frequency, the most common frequency being 60 cycles. These speeds are, of course, too great for motors of any size, so that bipolar construction is seldom if ever used. The smallest machines are usually given four poles, and the number increases with the size of the machine and the frequency for which it is intended. The armature for a four-pole motor, evolved from the bipolar form of Fig. 14, would be constructed as indicated in Fig. 15. However, as there is no tendency for the currents in the two windings to interfere with each other, there is no reason why the two groups should be insulated from each other, so that the construction used in practice is made as shown in Fig. 16—the "squirrel cage" type.

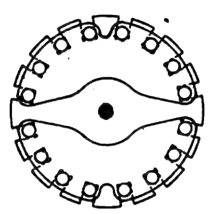

FIG. 15.

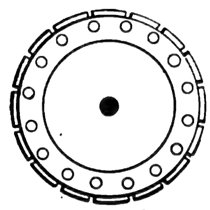

FIG. 16.

Letters on Practical Subjects

Curious Phenomena Resulting From Electric Discharges.

I enclose herewith a photograph which may be of interest to your readers, the circumstances surrounding the case being rather peculiar. One of the secondary leads from a large coil passed within six inches of an upright post on another instrument. During some experiments in wireless telegraphy considerable leakage was noticed and with every discharge a slight click was heard. This noise was finally traced to a discharge passing from the lead to this instrument. In order that better insulation might be had, a beaker was placed over the top of the post and the wire secured a little farther away. The discharge was not then so distinct and appeared to come from another point in the lead, although it could not be found, the insulation being very high. After the series of experiments the beaker was taken off the post, but to our surprise was freely spotted with small white spots. The beaker was placed on a shelf and was not touched again for two days. As a further surprise it then presented the appearance shown in the photograph, the bottom and sides for a distance of one decimeter from the bottom be-

FIG. 1.—FRACTURED BEAKER.

ing literally honeycombed with small irregular fractures. The photograph does not show the shape of these spots very well, but they are between one and two centimeters in length and very irregular in shape. None of them extend far enough to intersect one another. Although some time elapsed during the development of these perforations, no apparent change has taken place during the many months that have elapsed since.

Quincy, Mass. R. G. GRISWOLD.

A Curious Transformer "Deposit."

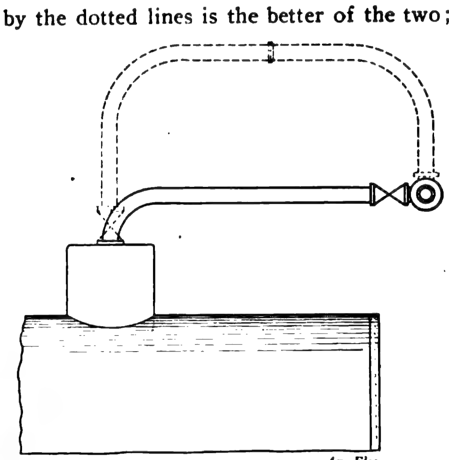
I enclose in this letter some globules of copper which were found in the bottom of the case of a large oil transformer that burned out some time ago. We found a large number of perfect balls of copper about the size of "BBB" shot and smaller, and we were much puzzled with their lightness. On cutting them open we found that they were nothing but perfect hollow globes or balls. They were given to different parties before it occurred to me to write to you, so cannot send you any good samples. It probably is a common occurrence, but it is the first time that I have noticed anything of the kind.

F. O. BROILI.

Virginia City, Nev.

Boiler Connections.

The accompanying sketch shows two methods of arranging the delivery pipe leading from a boiler to the main steam header. I have contended that the method indicated by the dotted lines is the better of the two;



BOILER CONNECTIONS.

others argue in favor of the arrangement shown by solid lines. I should like to have readers of the AMERICAN ELECTRICIAN state their preferences, giving the reasons for them.

M. E. WALTHALL.

Coalton, W. Va.

Storage Battery Operation.

In an installation of storage batteries used in conection with telephone switchboards I have noticed that the batteries are charged until the voltmeter indicates 20 volts on an 8-cell battery, or 2½ volts per cell immediately upon disconnecting the battery from the charging circuit, the voltage fell to 17½ volts. I have looked up the subject of storage battery charging in all the available text books and articles, and find that none of them states definitely whether the battery should be charged until it shows 2½ volts per cell *disconnected*, or that voltage before

disconnecting from the charging circuit. My experience is that batteries are handled by many men who are not quite clear on that point, and it seems to me that discussion of it might be of interest.

R. P. BRYAN.

Walla Walla, Wash.

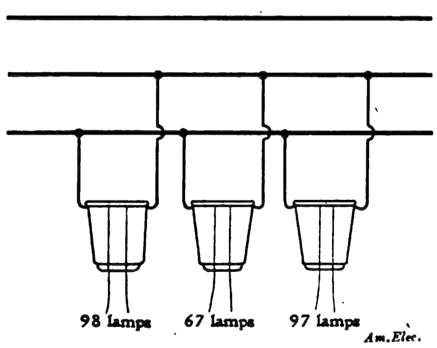
[The voltage at the terminals of the battery is not the only criterion as to the time to cease charging it, although in most cases it is a sufficiently effective guide. When it is made the deciding factor, it is, we think, generally understood that the 2½-volt limit is intended to mean the voltage just before disconnecting from the charging circuit. It is very doubtful that a battery could be charged to such a point as to enable it to give 2½ volts per cell *after* removal from the circuit.—EDITOR.]

A Transformer Trouble.

Three transformers connected to the same phase of a two-phase primary circuit behave in a peculiar way. The transformers are of 100 lights capacity each, and the normal loads are 98 lamps on *A*, 67 lamps on *B* and 97 on *C*. When a group of 17 or 18 lamps is cut out from either *A* or *C*, the fuse in the circuit of *B* blows. I should like to have some of the AMERICAN ELECTRICIAN readers suggest the cause and a remedy.

ERNEST ANDERSON.

Moroni, Utah.



MR. ANDERSON'S TRANSFORMER TROUBLE.

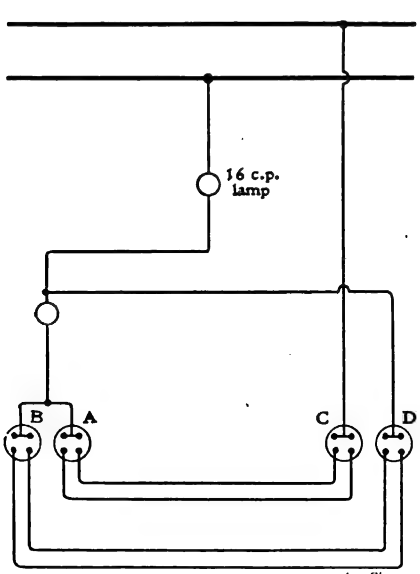


FIG. 2.—MR. DILLON'S SOLUTION.

Mr. McHugh's Problem in Switch Connections.

Enclosed is a diagram of connections (Fig. 1) submitted as a solution of Mr. McHugh's problem which appeared last month. The switches *A* and *C* control the entire lamp circuit on the familiar two-station principle; when the lamp is operatively connected to the line, either switch will extinguish it, after which either of them will relight it. The switches *B* and *D* control a short-circuiting circuit around the resistance lamp in the same way.

W. G. BRANDON.

Marion, Ind.

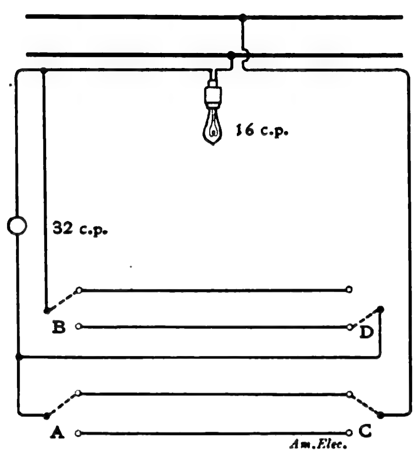

FIG. 1.—MR. BRANDON'S SOLUTION.

[Exactly the same diagram was sent in by Messrs. William Merrill, of Wilmington, Del., and H. C. Storm, of Yonkers, N. Y.—EDITOR.]

The accompanying diagram (Fig. 1) shows one way of obtaining the results described in Mr. McHugh's problem in lamp control published in the December number of the AMERICAN ELECTRICIAN. The switches *A* and *C* control the admission of current to the lamp circuit and the switches *B* and *D* control a short-circuit connection around the resistance lamp.

LAWRENCE BRODE.

Colton, Cal.

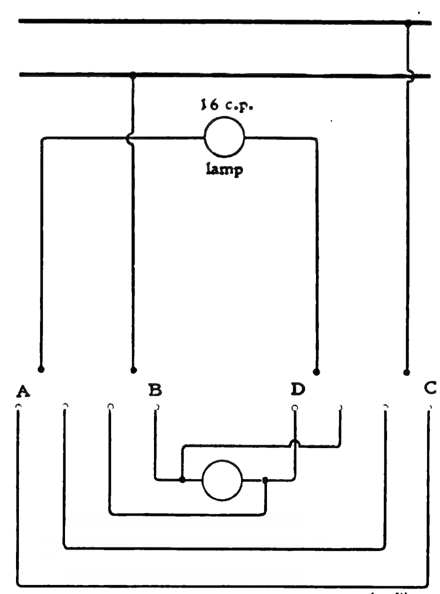

FIG. 3.—MR. EUSTACHIO'S SOLUTION.

I send herewith a solution (Fig. 1) of Mr. McHugh's problem in the December number of the AMERICAN ELECTRICIAN. The switches are all three point, or single-pole two-way, snap switches; the effect of each pair is obvious from an inspection of the diagram.

H. B. BROWN.

Schenectady, N. Y.

Herewith I submit a solution (Fig. 2) of Mr. McHugh's problem in lamp and switch connections. The switches *A* and *C* light and extinguish the lamp and the extra pair of switches simply short-circuit the resistance lamp and remove the short-circuit, thereby affecting the brilliancy of the 16-c.p. lamp.

JAMES DALZIEL.

Brooklyn, N. Y.

[This solution is practically the same as Fig. 1, there being only a slight difference in the wiring details.—EDITOR.]

The accompanying diagram (Fig. 2) is submitted as a solution of Mr. McHugh's switch-connection problem published last month. The operations are obvious.

JAMES B. DILLON.

Louisville, Ky.

Referring to Mr. McHugh's problem in lamp control, I offer the accompanying diagram (Fig. 2) as a solution. The switches *A* and *C* cut the lamp in and out of circuit successively, and when it is in circuit, the extra switches *B* and *D* short-circuit the resistance lamp in series with the regular lamp, or remove the short-circuit, thereby controlling the brightness of the 16-c.p. lamp. This is the only way I can see by which the desired results can be obtained with three-point switches.

G. F. ERFURTH.

Fort Smith, Ark.

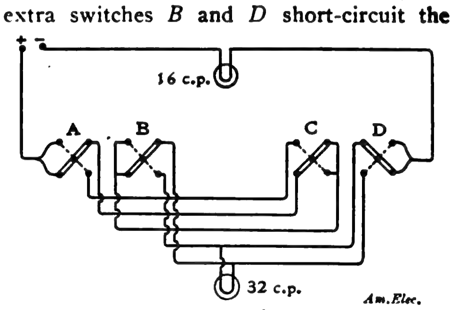

FIG. 4.—MR. FRASER'S SOLUTION.

The accompanying diagram (Fig. 3) shows one way of accomplishing the results specified in Mr. McHugh's letter last month. The 16-c.p. lamp is connected between the common points of the switches *A* and *D* and the resistance lamp is connected across the alternative leads between the switches *B* and *D*. The switches *A* and *C* control the admission of current to the lamp direct and *B* and *D* complete the circuit either from the 16-c.p. lamp direct or through the resistance lamp.

G. D. EUSTACHIO.

Pittsburg, Pa.

I submit the accompanying sketch (Fig. 4) as a solution of the problem in switch connections offered last month by Mr. Mc-

Hugh. With the switches set as in the diagram, the 16-c.p. lamp would be connected to the supply circuit in series with the resistance lamp. Turning either *B* or *D* would leave the resistance lamp out of the active circuit and allow the regular lamp

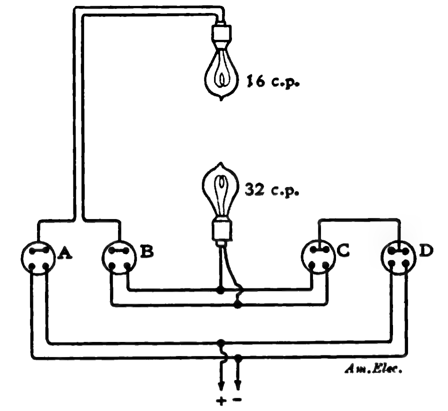

FIG. 5.—MR. FREASE'S SOLUTION.

to burn at full candle-power. Turning either *A* or *C* would disconnect the lamp circuit from the positive side of the line. Another turn of either switch would restore the conditions existing before its mate was turned.

CLARENCE L. FRASER.

Pulaski, N. Y.

The enclosed diagram (Fig. 5) is a solution of Mr. McHugh's lamp connection problem in the last number of the AMERICAN ELECTRICIAN. One terminal of the 16-c.p. lamp is connected to one or the other main line terminals by the switch *A;* the other terminal, in circuit with which are the switches *B* and *D* and the resistance lamp,

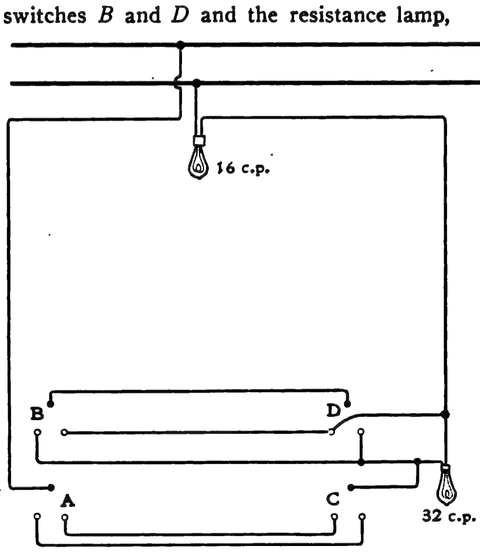

FIG. 6.

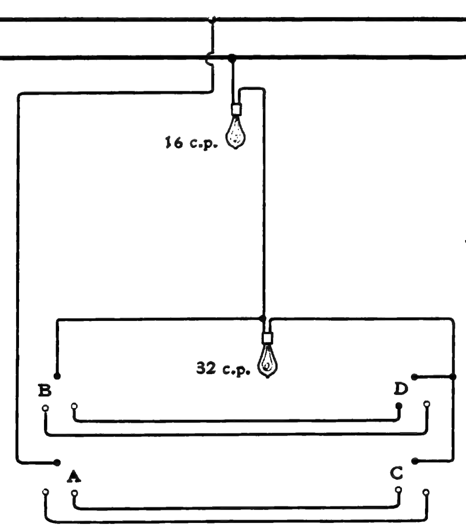

FIG. 7.

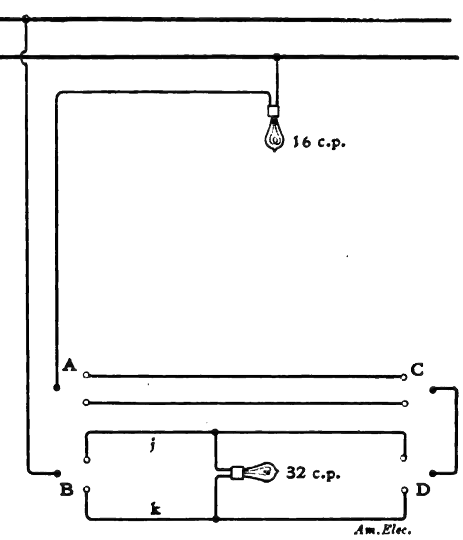

FIG. 8.

is similarly controlled by the switch *C.* The switches *B* and *D* merely determine whether the resistance lamp is in series with the regular lamp or not.

G. E. FREASE.

Youngstown, Ohio.

I send herewith (Fig. 4) a solution of Mr. McHugh's problem in switch connections which appeared in this department last month. The diagram is practically self-explanatory.

RICHARD GESSNER.

Oak Park, Ill.

[The operation is, of course, as described in Mr. Fraser's letter, preceding. The same diagram was sent in by Mr. W. H. Middleton, Jr., of Prince Bay, N. Y.—EDITOR.]

The enclosed sketches (Figs. 6, 7 and 8) indicate three ways of solving the lamp

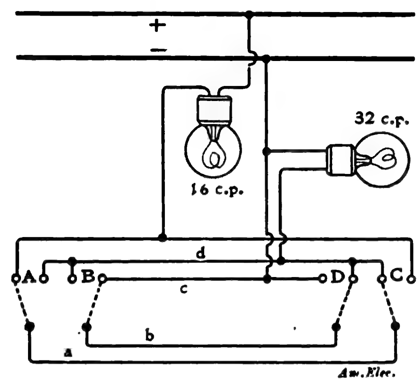

FIG. 9.—MR. M'DONALD'S SOLUTION.

and switch connection problem published in this department last month. In the first two, the resistance lamp is either short-circuited or left in circuit by the switches *B* and *D;* it is permanently in series with the 16-c.p. lamp. In Fig. 8 the resistance lamp and the switches *B* and *D,* considered as a group, are in series with the 16-c.p. lamp and the switches complete the circuit either through one of the wires *j, k,* or through half of each wire and the resistance lamp. In all three solutions, the switches are two-way, single-pole, snap switches, and those marked *A* and *C* light the lamp or put it out in the ordinary way peculiar to two-station lamp control. The last solution (Fig. 8) is the best one for several reasons, chiefly because it requires only four wires between the two stations switch instead of five.

GEORGE W. MALCOLM.

Brooklyn, N. Y.

[Fig. 8 was also sent in by Mr. M. H. Stillman, Austin, Minn.—EDITOR.]

The enclosed diagram (Fig. 1) is a solution of the lamp connection problem published last month. The three-point, snap switches are represented conventionally like battery strap switches. With the switches set as indicated by the dotted lines, the lamps will be connected in series to the supply line. Throwing either *B* or *D* will short-circuit the resistance lamp and let the 16-c.p. lamp burn at full power. Throwing either *A* or *C* will put out the lamp. Another turn of *A* or *C* will put it back in circuit with the resistance lamp short-circuited, and a

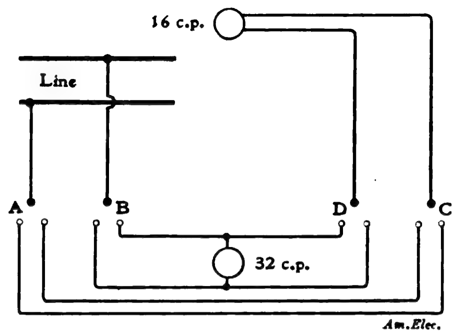

FIG. 10.—MR. MOORE'S SOLUTION.

turn of either *B* or *D* will put the resistance lamp back in circuit.

L. P. MANSFIELD.

Cambridge, Mass.

Enclosed I submit a solution (Fig. 9) of Mr. McHugh's problem in switch connections. My understanding of the problem is that the 16-c.p. lamp is to be turned on or off from either station and when on, it is to be dimmed by means of a resistance lamp or left bright, at will, from either station. Referring to the sketch, the switches are in position for the lamp to burn at full power; the current path being from + to the lamp, through switch *A,* wire *a,* switch *C,* switch *D,* wire *b,* switch *B,* wire *c,* and to the negative line. Throwing either *B* or *D* would send the current from switch *C* to the resistance lamp, and the next throw of either of them would short-circuit the resistance lamp again. The two switches *A* and *C* work on the two-station control plan; throwing either of them from the position shown would open the lamp circuit, after which throwing either of them would restore it.

L. R. MCDONALD.

Montreal, Can.

The lamp and switch connection problem

published last month can be solved by the arrangement shown by the enclosed diagram (Fig. 10). The switches are all two-way, single-pole, snap switches. One of the leads from the 16-c.p. lamp is connected to or disconnected from the line by means of the switches *A* and *C*; the other lead is connected to the line either direct or through the resistance lamp by means of the switches *B* and *D*, one or the other connection being always made. Thus, the lamp may be lighted or put out at either point of control, and when it is lighted, it may be dimmed or "undimmed" from either station.

W. H. MOORE.

La Grange, Ill.

[Exactly the same solution has been furnished by Mr. Charles B. Smeeth, of Ironwood, Mich.—EDITOR.]

The accompanying sketch (Fig. 11) shows one way of accomplishing the results described in Mr. McHugh's letter last month. The switches *A* and *C* operate in the usual way for two-station lamp control; the switches *B* and *D* either insert in or remove from the lamp circuit the resistance lamp. In the diagram, the main lamp is in circuit direct, the resistance lamp being connected to the circuit only at the left-hand terminal. If the switch *B* is thrown over, the current coming to that switch from *C* will go through the wire *m* to the junction *x*, and back through the resistance lamp, to the wire *n* and on to the switch *D* and the main lamp. If, on the other hand, the switch *B* is left as it is and *D* is thrown over, the current from *B* must pass over to *D* through the resistance lamp instead of the wire *n*; in both cases the resistance lamp will, of course, be in series with the main lamp.

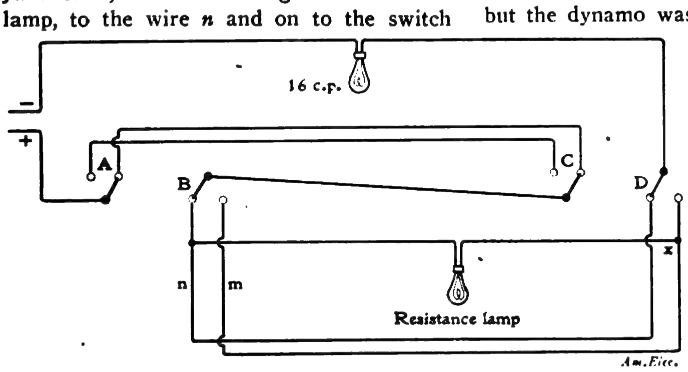

FIG. 11.—MR. RICHARDSON'S SOLUTION.

GEORGE W. RICHARDSON.

Chicago, Ill.

The accompanying diagram (Fig. 12) is submitted as a solution of the problem in lamp control which appeared last month. The switches *A* and *C* light and extinguish the lamp in the way peculiar to two-station control with three-point switches, using the wires *m* and *n*. The switches *B* and *D*, if manipulated in combination with *A* and *C* respectively change the circuit from the wire *m* or *n* to the middle wire in which is inserted the resistance lamp. For example, with the switches as shown in the diagram, the lamp is extinguished; throwing either *A* or *C* will light it at full power; or throwing either *B* or *D* will light it with the resistance lamp in series with it. When the lamp is in circuit at full power, throwing either *A* or *C* will put it out; or throwing both *A* and *B* together or *C* and *D* together will dim it by inserting the resistance lamp.

LOUIS J. GORILLA.

Ironwood, Mich.

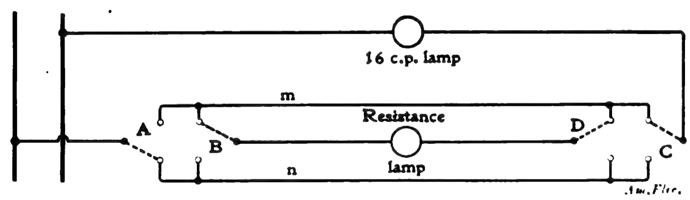

FIG. 12.—MR. GORILLA'S SOLUTION.

An Odd Dynamo Trouble.

The other day, what is I think a rather mysterious occurence, happened to me, and for the reason that I would like to have the mystery explained, and that I think that it might be of interest to some of my fellow readers, I herewith submit the facts of the case.

I was called in to see what I could do for a small dynamo that refused to "pick up" its load. The dynamo is a brand-new 10-kw., direct-current machine, with four poles, compound-wound. The four brushes are connected in the usual manner, the leads being taken off the two lower ones.

An expert was there, and had been running the machine. He said it had given no trouble until this time, when he had shut down to show the man who was to have charge of the plant something about the engine. When, ten minutes later, he tried to start up again the dynamo was "dead." I examined the connections and found them all right, and the machine free from grounds (in itself). We started up again, but the dynamo was "dead as a door-nail." I short-circuited the line, and then the rheostat, with equally negative results. I was standing over the machine, looking at the voltmeter when, accidentally, I let the screw-driver, which I held in my hand, come in contact with the two upper brush-holders. There was a flash which "fixed" the screw-driver and the dynamo, too, for it "picked up" instantly, and has given no trouble since. I examined the machine again, and could find no trace of what happened in it, except the short-circuit caused by the screw-driver.

ALBERT G. FULTON.

Oconto, Wis.

Problem in Motor Connections.

The accompanying diagram (Fig. 1) represents a 5-h.p. motor installed in a basement with a speed-regulating rheostat near it, and a starting box, *S*, on the floor above. The speed-regulating rheostat is operated automatically, so that there is no need for anyone to go downstairs in the ordinary course of operation. It is desired to install a 1/6-h.p. fan-motor near the 5-h.p. machine for ventilating purposes, and to connect it to the supply circuit so that when the larger motor is started up the little one will be started also but its speed must not

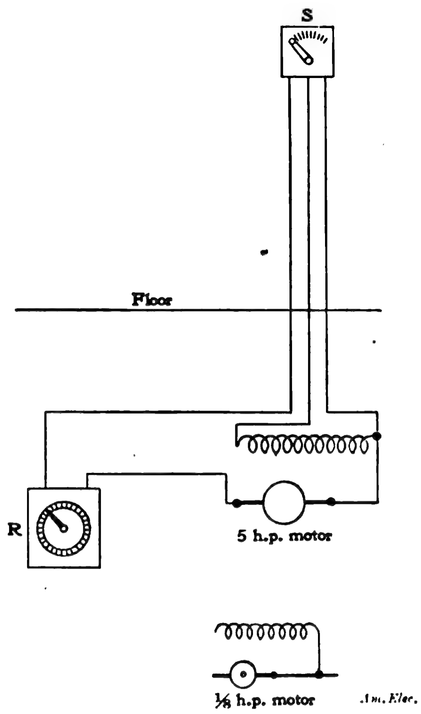

FIG. 1.—PROBLEM IN MOTOR CONNECTIONS.

be affected by the speed-regulating rheostat, *R*. After being started, it must run at full speed, regardless of the speed of the larger motor. The supply circuit enters the starting box, *S*, from above, and does not go down into the basement at all. The connections are to be made with the least possible quantity of wire. I should like for readers of the AMERICAN ELECTRICIAN to suggest the proper connections.

GEO. W. MALCOLM.

Brooklyn, N. Y.

Lamp Coloring Compound.

If any reader of the AMERICAN ELECTRICIAN knows of a good recipe for making coloring compound for incandescent lamp bulbs, I would appreciate highly the publication of it in this department. I have tried one or two recipes, but the compound does not last any length of time; the least handling or exposure to weather causes it to wear off in spots until it is practically ineffective.

K. G. LITTLE.

Atlanta, Ga.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

What is the best way to make storage batteries? (2) How should a new battery be charged the first time? (3) Can rubber or composition jars be cemented where they have been cracked? S. E. H.

(1) and (2) The subject cannot be treated adequately in the space available in this department; "Electrical Designs" contains instructions of this kind; the price is $2.00. (3) Not satisfactorily.

How can a 6-volt, 4-ampere dynamo, with No. 16 wire in the armature and Nos. 18 and 13 in the field (compound-wound) be changed to 110 volts? (2) What will the output in amperes be? J. W. W.

Rewind the armature with No. 29 silk-covered wire, putting 19 times as many turns in each coil as there are now. Rewind the shunt coils with No. 31 silk-covered wire to the same dimensions as the present coils. Rewind the series coils with No. 26 single-cotton-covered wire, putting 19 times as many turns per coil as there are now. (2) About 0.2 ampere.

Why will a rotary converter give a greater output operated six-phase than it gives as a three-phase machine? (2) In transposing line wires to neutralize inductive effects, must the same one of the wires always cross over the other, or can the two be spiraled? (3) If spiraled, with two circuits on one pole line, should the spirals of the two circuits be in the same direction, or should one be right-handed and the other left-handed? C. E. F.

Because the disposition of currents in the armature winding is more favorable as to heating, so that more current can be carried with the same rise of temperature. (2) and (3) It makes not the least difference.

If a 6-pole motor, having a lap-wound armature with 6 paths, were operated with the field magnet coils on two diametrically opposite poles cut out of circuit and the two sets of brushes corresponding to these poles lifted from the commutator, what would be the results? The machine has equalizer connections on the armature winding. (2) What would happen if two adjacent field magnet coils were cut out? W. M. S.

Excessive currents would flow in the equalizer connections and the current density under the remaining brush faces would be excessive; it would be better to leave all of the brushes on the commutator. (2) The same results as in the first case; also an unbalancing of the magnetic field which might cause seriously excessive friction in the bearings.

Is it good practice in wiring a house already built to fish the conductors up between the walls of the first floor to side fixtures and drop the lights from the ceilings of the second floor? (2) Can both conductors of a circuit be put in one flexible conduit? (3) Should a cut-out be used on the outside of a building where wires enter it? (4) Is it common practice to use cross-arms carrying more than four pins for light and power wires? (5) Is it good practice to run an alternating-current 1100-volt circuit over and parallel to a telephone line. S. C. R.

It is so far as the wiring is concerned, but the illumination on the first floor will not be as good as with ceiling lights. (2) Yes. (3) Not necessarily. (4) Yes; 6-pin arms are frequently used. (5) It is preferable not to do so, but it is often unavoidable.

In testing a three-phase alternator with a submerged iron-wire resistance for a load, the ammeters in the three leads from the armature indicated (a) 46, (b) 74 and (c) 48 amperes respectively, at the same time. The 46-ampere lead was connected to one terminal, A, of the resistance coil, the 74-ampere lead to the exact center of the coil and the 48-ampere lead to the other extreme end, C; what caused the difference between the current in the middle lead and those in the other two? J. I. D.

The current in the lead b was the combination of the other two; if a resistance coil of half the resistance of the one used had been connected to the terminals A, C, of that one, without changing any of the connections, the three currents would have been substantially equal.

Should the field winding of a repulsion motor be a single winding, like that of a series-wound, direct-current motor, or divided into two groups like the starting and working winding of a self-starting, single-phase induction motor? (2) Is it necessary to use a continuous notched ring, as in an induction motor, or can projecting poles be used? (3) What is the relation between the field and armature windings? (4) Why will such motors not run on all frequencies? (5) Are they not the best for hoisting, ventilating fans, cranes, etc.? F. B. A.

Only one field winding is required. (2) Either construction may be used. (3) The question is obscure. The field winding is connected to the source of supply; the armature winding is short-circuited through the brushes. (4) Because of the self-induction at high frequencies. (5) Not necessarily; they are probably better than the ordinary induction motor.

Why are idle or "dead" segments sometimes put in the commutators of direct-current dynamos? (2) How does the charging current of an alternating-current transmission line raise the voltage of the line? (3) What troubles result from opening such a line when it is loaded or short-circuited? F. A. B.

Such segments are used only in the commutators of "open-coil" arc-lighting dynamos, to separate the active segments widely and prevent the "spark" at the brush from welding them together. (2) It doesn't; the electrostatic capacity of the line combined with its inductance, is what raises the voltage. It is impracticable to explain this satisfactorily here; see any text-book on alternating-current principles. (3) Unless opened at the instant when the alternating current is very near zero, a sudden rise in e.m.f. which may puncture insulation in the connected apparatus.

How can the positive and negative brushes of a multipolar dynamo be identified before carrying the leads to the switchboard? (2) Why does the negative wire of a dynamo circuit produce nearly the same effect as the positive wire when touched with the hand by anyone standing on the ground? H. H. T.

By applying a voltmeter of the permanent magnet type to the different pairs of brushes; when the + post of the meter is connected to the negative brush and the other post to the positive, the needle is thrown against the back stop; when the + post is connected to the + brush and the other post to the negative brush, the needle is deflected over the scale. (2) Because there is a leakage path to the earth from some part of the armature winding and the person touching the wires gets about the same difference of potential from either wire to the ground.

How much discrepancy is allowable between the individual voltages across different pairs of brushes on a multipolar machine? (2) In drying out a dynamo with its own current, should the machine be started up under short-circuit or should it be brought up to a low voltage before short-circuiting the armature? (3) Should the series field winding be cut out while drying out? M. S.

None; the voltage between every pair of brush groups of opposite polarity should be exactly the same. If this condition cannot be obtained without shifting some of the brushes away from the proper commutating position, the machine should be overhauled. (2) and (3) It should be started up under short-circuit through an ammeter, with the series field winding in circuit, and the shunt field rheostat cut out, provided the speed can be accurately adjusted to keep the current down; if not, the series winding should be cut out of circuit and the machine started up under short-circuit through the ammeter, with the shunt field rheostat all in.

What connections are necessary to take two-phase and three-phase currents from a lap-wound armature in a 4-pole, direct-current machine? (2) If direct-current be passed through the stator winding of an induction motor, will the polarity of the groups of teeth embraced by the successive coils be alternately north and south? F. M.

For two-phase current, connect two diametrically-opposite commutator segments and carry a tap from them to one collector ring; connect two other opposite segments exactly half-way between the first two and carry a tap to a second ring; this is one phase. Connect the other two rings to two pairs of segments exactly half-way between the first two pairs, the two segments of each pair being always diametrically opposite. For three phases, one of the collector rings of the two-phase set may be used; if the commutator segments be numbered consecutively all around the barrel, and the first two-phase ring is connected to Nos. 1 and 37, using this for one of the three-phase rings, the other two rings must be connected one to segments 13 and 49, and the other to segments 25 and 61. (2) Yes.

What is the relation between the pull of a stopped solenoid excited from a direct-current circuit and from an alternating-current circuit, the winding being the same in both cases? (2) In what part of the circuit of an induction motor should a solenoid be connected for best results? (3) In an adjustable starting resistance for induction motors, should each phase be provided with a resistance and switch contacts? (4) What is the best form of resistance to use? (5) When breaking a polyphase circuit, should all of the legs or phases be opened? (6) Can I obtain copies of the April and May, 1901, AMERICAN ELECTRICIAN, or, if not, can I get copies of the articles on windings for magnets and solenoids published in those numbers? H. W. Z.

There is no definite relation; the winding must be designed especially for alternating current. (2) That depends on what it is desired to accomplish; if the magnet is to operate without reference to the current flowing in the motor, it should be connected across two of the leads. (3) Yes. (4) For small machines thin copper ribbon arranged non-inductively for large ones, either carbon rods or a submerged rheostat having conductors of non-magnetic material. (5) Yes. (6) The numbers are out of print; the articles will be published in book form with much additional material, probably within the next three months.

POWER PLANT OF ANHEUSER-BUSCH BREWING ASSOCIATION, AT ST. LOUIS.

The electric generating plant and refrigerating machinery of the Anheuser-Busch Brewing Association in St. Louis, Mo., are located in one building having a side on Ninth Street and facing Pestalozzi Street, where the general offices of the Association are situated. The boiler house which contains a battery of eleven 500-h.p. Heine water-tube boilers is about 500 feet from the engine room. There are three main steam lines to the power and refrigerating

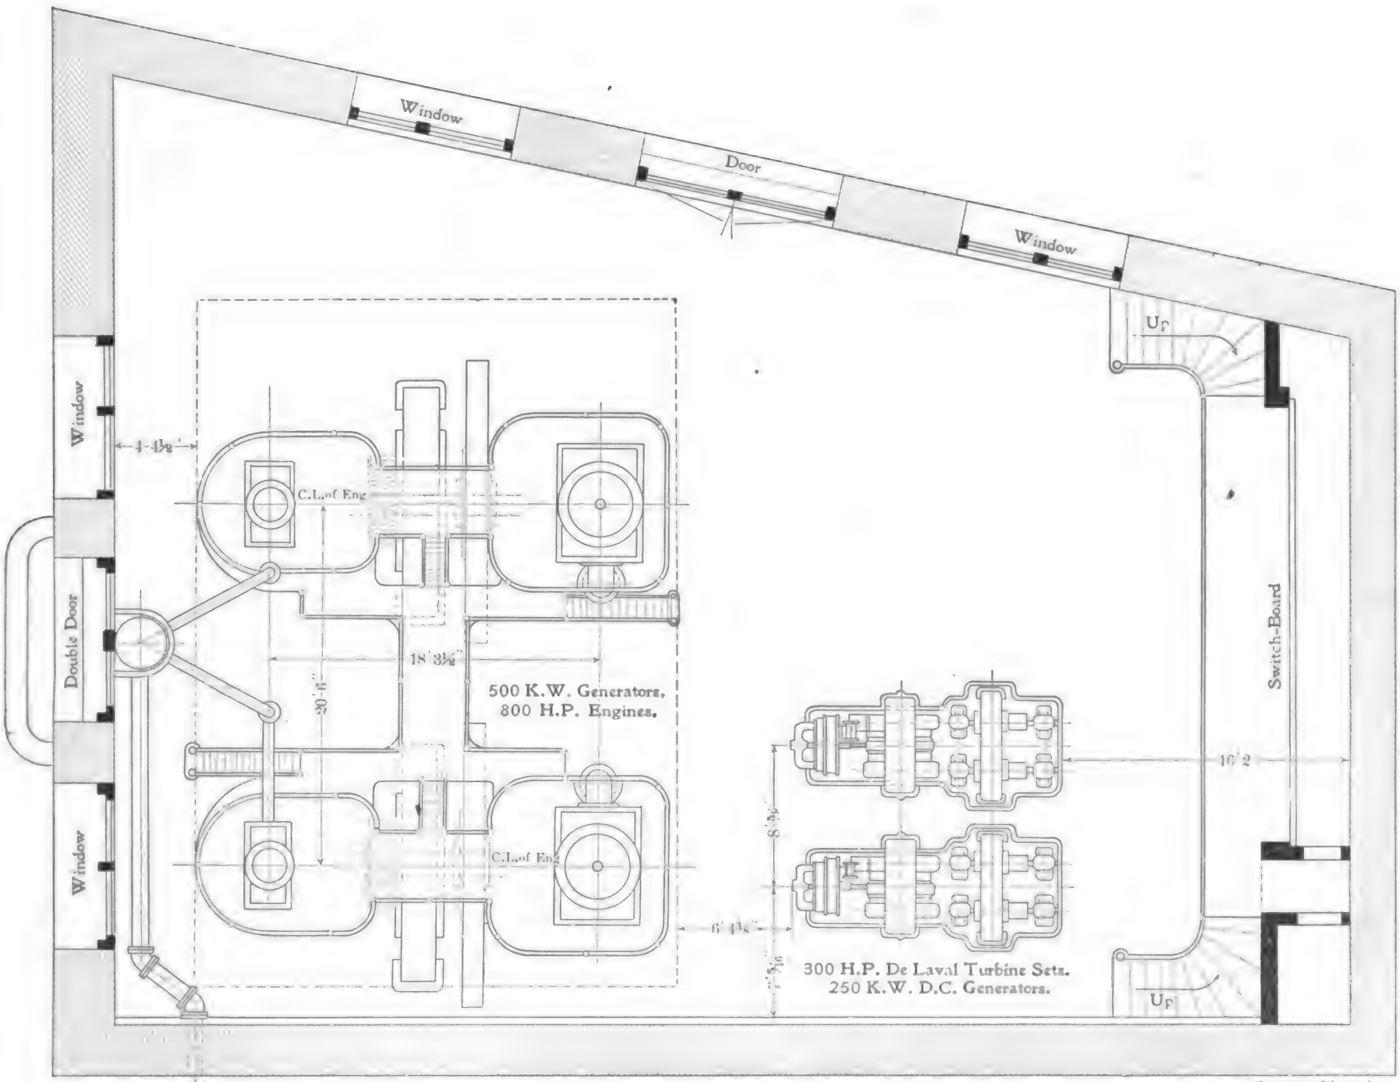

FIG. 1.—PLAN OF THE POWER PLANT OF THE ANHEUSER-BUSCH BREWING ASSOCIATION.

plant, one 18 in., one 14 in. and one 12 in.

The electric power plant consists of two 750-h.p. vertical compound Corliss condensing engines, built by the Fulton Iron Works in 1901. These engines have 21-in. and 42-in. cylinders, and a stroke of 48 ins. The steam pressure is 140 lbs., and speed 90 r.p.m. They are direct connected to 500-kw. General Electric 240-volt direct-current generators. These, with the two 200-kw. De Laval steam-turbine dynamos, give a total normal capacity of 1400 kilowatts The two 300 b.h.p. turbines are of standard De Laval type, each direct connected to a pair of 200-kw., 240-volt direct-current generators, built by the Bullock Electric Manufacturing Company, and operate under 140 lbs. steam pressure and a vacuum of 27 ins.

Fig. 1 shows in outline the general arrangement of the engine room, and Fig. 2 is a view of the turbine units. The steam guarantees given by the De Laval Steam Turbine Company in connection with these machines, were as follows:

Full load—17.9 lbs. of dry steam per B. H. P. per hour.
Half load—20.1 lbs. of dry steam per B. H. P. per hour.
Quarter load—24.9 lbs. of dry steam per B. H. P. per hour.

These guarantees were for 140 lbs. steam pressure and 26 ins. vacuum, and on acceptance test recently run the steam consumption came well within these figures, and the machines were accepted.

The normal requirements of the plant are sufficient to keep one engine and one turbine fully loaded, thereby making it possible to hold one engine and one turbine in reserve at all times.

The exhaust steam from the engines is led into a Wheeler surface condenser of 1500 horse-power capacity. Condensing water from the cooling towers is circulated through the condenser by a 10-in. Wheeler centrifugal pump driven by a 50-h.p. Bullock direct-current motor. The condensed steam and air are removed together by means of an Edwards triplex wet vacuum pump driven by a 10-h.p. Bullock motor, whose speed may be varied by means of a multiple voltage system.

The condensing apparatus for the steam turbines is a duplicate of that installed for the compound engines, with the exception of the circulating pump, which is an 8-in. centrifugal pump built by the Kingsford Foundry & Machine Works. Each exhaust line is provided with a 24-in. relief valve, which opens to the atmosphere. Cochrane separators are installed in the steam lines and numerous traps drain the piping, separators and turbine steam chambers.

The oil from the engines is drained into a filter and then pumped by means of the Siegrist automatic oiling system, to the engines, where it is fed under pressure. The turbine oiling system is independent of the engine drainage, but is essentially the same in its operation.

The electric cables from generators, after passing through and under the floor, are led through ducts behind the massive switchboard which is erected above, on the operating gallery. The switchboard is made of heavy panels of white Vermont marble and covers nearly the entire wall at one end of the engine room. There are 32 panels in all, but only 20 of them are now in use. The voltmeters and ammeters are of the Weston standard station type,

and may be read from the floor some distance below, by means of their illuminated scale. Each main and feeder circuit is provided with an I-T-E circuit breaker. The switches are all of heavy construction and neat design.

The greater portion of the load on the generators is used in driving motors distributed all over the large brewing plant, for operating automatic malting machinery, bottling machines, elevators, fans, blowers, pumps and for charging storage batteries used on the electric delivery truck. This entire plant was designed and erected under the supervision of Mr. Ernest Ruebel of Ruebel-Schwedtman-Wells, consulting engineer for the Association.

The engine room is well lighted and is one of the handsomest in the West. The walls have a wainscoting of glazed tile, and the floor is laid with tile of a pretty design. Engines and turbines are painted a deep red color, and are striped with gold leaf. An automatic Otis electric elevator is installed for the use of the attendants in going about from the condenser room, which is underneath the turbines to the floor above, where the brine-cooling coils for refrigerating machinery are located.

NEW GENERATING SET.

The B. F. Sturtevant Company, of Boston, Mass., has brought out the generating set shown by Fig. 1 herewith, which is said to embody many new features. The general design of the engine is said to include all the latest improvements to the horizontal type. The reciprocating parts are substantially constructed and counterbalanced with lead load discs. A feature of construction is that of forging the crankshaft solid in one piece and shrinking the discs onto it. A special arrangement of the Rites' governor is said to give a regulation within 1 to 1½ per cent from full load to no load, and by a modification of the Marshall valve gear an adjustment of the cut-off from zero to 70 per cent is attained. The main bearings, crankpin, valve stem and slides are babbitted with the Sturtevant white metal. A recent improvement is the water-shed partition which prevents the water from the piston rod stuffing box from reaching the interior of the engine frame, and the oil on the reciprocating parts from being thrown out into the engine room. The main body of the engine is enclosed on both sides by removable plates, as may be seen from the illustration, and the crank webs are enclosed by a cast-iron hood having two holes with removable covers, one for the purpose of cleaning the crank-pin box while it is in motion, and the other for removing the box without taking off the large hood. Between the watershed partition and the front end of the cylinder, is a hand hole for reaching the stuffing box bolts without communication to the oil spaces. There are two oiling systems for this type of engine, the gravity or tank system and that by forced pump lubrication. The generator of this set is of the eight-pole type, and is said to be capable of carrying momentary overloads of 50 per cent without any shifting of brushes or flashing of the commutator, and an overload of 25 per cent for a period of two hours without undue heating. The average temperature rise is about 33 to 35 degs. C. Before being shipped, the generator is given a break-down test of 1500 volts, alternating for sixty seconds between the conductors and the frame of the machine to test the insulation. The magnet frame is of cast iron, split horizontally. The pole pieces are of wrought iron with cast iron shoes, and are secured to the magnet frame by through bolts. Any of the pole pieces may thus be removed to repair the field coils. The latter are wound up in two sections, with an air space between the shunt and series coils. The shunt winding is a double cotton-covered magnet wire, the series winding is of solid copper bars insulated in the same manner as the shunt coil. The armature is of the ironclad, form-wound, ventilated-drum type, having a core built up of charcoal iron plates, which after being thoroughly Japanned are mounted upon a cast iron spider and securely held in position by end flanges. No bolts pass through the armature laminations. The armature spider has an extension upon which is mounted the commutator making the armature and commutator one unit. The armature conductors are solid copper bars, without joints, except at the commutator end. In the construction of the commutator only drop-forged or drawn segments are used, these being secured in cast iron shells of spider construction and clamped in place with a steel ring. No cast segments of any nature whatever are used. The segments are insulated with mica, the end insulation consists of micanite rings and the whole commutator is assembled while hot, under pressure. Carbon brushes only are used, the commutator being so proportioned and the brushes of such size as to allow at least one square inch of brush area to every 30 amperes carried. These brushes are carried in holders of approved construction, each mounted upon a self-contained brush rigging so arranged that the entire set of brushes may be rotated completely around the commutator. Hand wheels are furnished for adjusting the brushes in position, these hand wheels being so located that the brushes may be adjusted from either side of the generator.

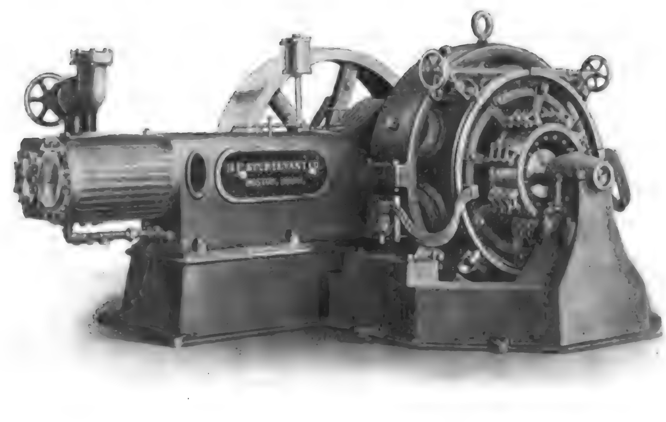

FIG. 1.—STURTEVANT GENERATING SET.

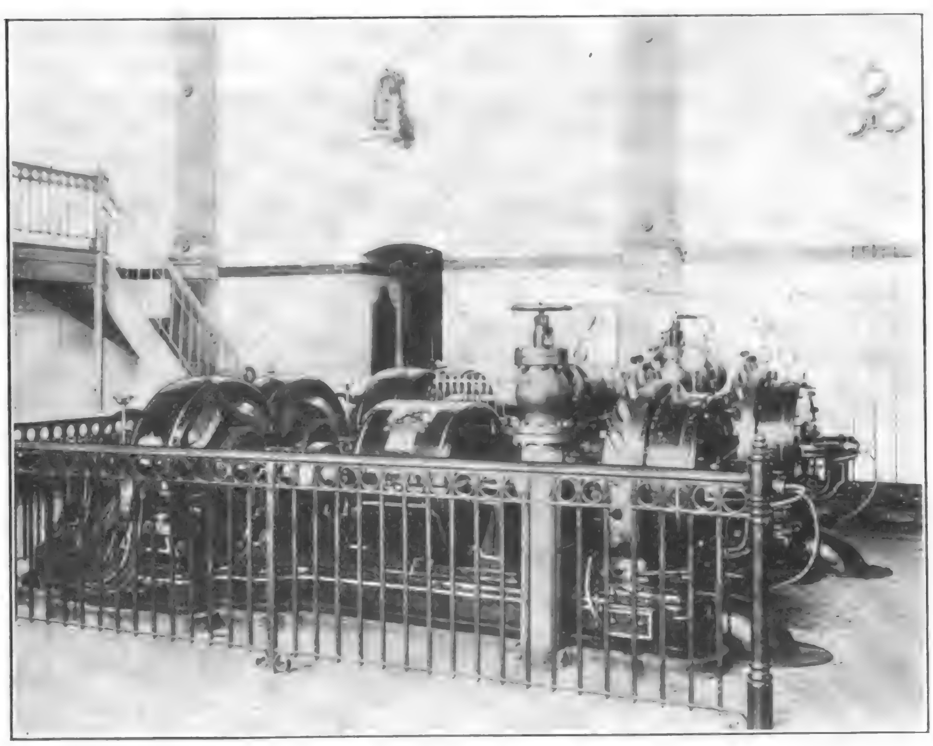

FIG. 2.—TURBO-GENERATOR UNITS IN ANHEUSER-BUSCH BREWERY.

New Apparatus and Appliances

EMERGENCY PIPE CLAMP.

James McCrea & Co., of Chicago, Ill., have brought out the emergency pipe clamp shown by Fig. 1 herewith. The clamp is made of malleable iron complete with packing ready for use. The clamp is easily

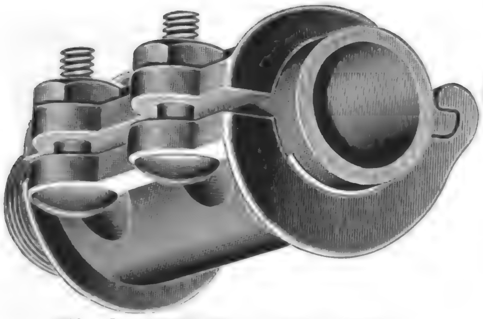

FIG. 1.—EMERGENCY PIPE CLAMP.

and quickly applied, and being compact, is available for pipes which are very close together, such as in coils. The lengths vary from 3¼ ins. to 4 ins., and the size of pipe from ½ in. to 4 ins. For the rapid repair of leaks and splits in pipes, the clamp should find a wide application.

SECONDARY SPARK COILS FOR JUMP SPARK IGNITION.

Fig. 2 herewith shows the "Fire Ball" jump spark coil made by the New York Coil Company, of New York City, which besides being waterproof is claimed to give a fatter and hotter spark with less expenditure of current than others of the same proportions. The coils are said to deliver a full ¾ in. spark with a primary poten-

FIG. 2.—"FIRE BALL" JUMP SPARK COIL.

tial of 6 volts. The contact points are made of platinum-iridium rivets and have large wearing surface. The coils are put up in oak cases and are furnished with or without a vibrator.

HANCOCK VALVES.

Fig. 3 herewith shows a globe valve made by the Hancock Inspirator Company, of New York City, in which many features of merit are combined. The globe, angle and cross valves made by the company are made of special composition, and are screwed and flanged in sizes up to 3 ins. The valves are made one standard only for all pressures. Under test the bodies of the valves are said to withstand a pressure of 4000 lbs., and to remain tight with a water pressure of more than 1000 lbs. per square inch. The discs are made of a special mixture which does not contain any zinc, and the spindles are made of Tobin bronze. From the illustration which shows a 1-inch globe valve, it will be seen that the area of the most contracted part of the valve is ample and of full size. The metal of the valves has been distributed to give uniform strength, and the area has not been reduced for the purpose of reducing the weight. Attention is called to the way the valve is guided on the stem. Two collars upon the stem guide the disc nut and prevent the disc from cocking. The valve seat is flat, and the valve disc has a

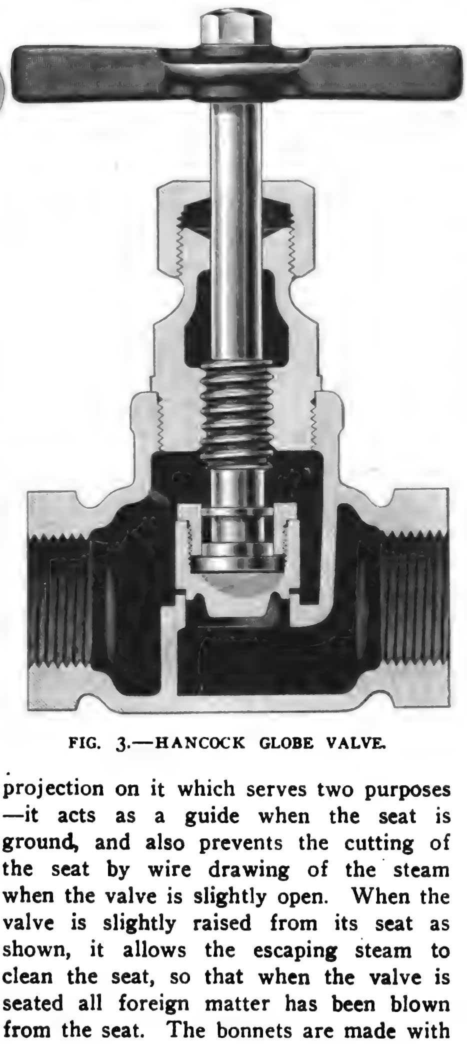

FIG. 3.—HANCOCK GLOBE VALVE.

projection on it which serves two purposes—it acts as a guide when the seat is ground, and also prevents the cutting of the seat by wire drawing of the steam when the valve is slightly open. When the valve is slightly raised from its seat as shown, it allows the escaping steam to clean the seat, so that when the valve is seated all foreign matter has been blown from the seat. The bonnets are made with

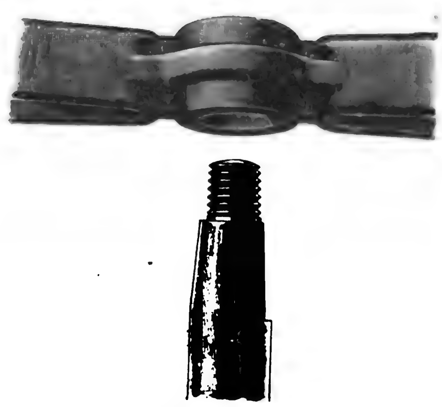

FIG. 4.—HANCOCK TEE HANDLE.

a long thread engaging the body of the valve and the shoulder of the bonnet is made narrow, which is said to be an improvement over the form having a wide shoulder bearing upon the wide surface on the top of the body of the valve. Fig. 4 herewith shows the peculiar method of attaching the tee handle. The hole in the handle is made tapering with one side flat, and the spindle of the valve is also made tapering with one side flat to receive the handle, the tee handle being held on the spindle by means of a nut.

NEW MOTOR CONTROLLER.

The type of controller shown by Figs. 5 and 6, and made by the Cutler-Hammer Manufacturing Company, of Milwaukee, Wis., is intended for the operation of machine tools or similar apparatus, in which the operator is within reach of the controlling handle, the speed regulation being effected entirely by means of shunt field control. The objects sought in design were the provision of a large number of field regulating points, the elimination of possibility of the motor starting on

FIG. 5.—MOTOR CONTROLLER.

weakened field, the operation of the device with a single lever in a simple and natural manner, and the returning of all parts to the starting position automatically under conditions necessitating this action. The apparatus consists of a motor starter of approximately standard construction, and a series of field buttons controlled by a field resistance lever mounted on the same hub post as the starter lever and co-operat-

FIG. 6.—MOTOR CONTROLLER.

ing therewith. In operation the motor is started and brought to speed by moving the handle to the right, this handle being attached to the field regulator lever which is mechanically connected to the starter

lever so as to move them as one piece in starting the motor. During this operation of starting, the field resistance is short-circuited by an auxiliary contact mounted on the starter lever and a curved sector located just below the armature contacts. When the two levers have been moved to the position in which all resistance is cut out of the armature circuit, a keeper on the starter lever is attracted by the retaining magnet, and the starter lever is held in this position. At this time also the auxiliary contact above referred to has left the curved sector thus removing the short-circuit from the field resistance. The field lever is now free for movement over the field rheostat buttons at the will of the operator, and may be left at any desired point, thus regulating the speed of the motor as desired. If the retaining magnet is de-energized either by failure of voltage or by operation of overhead release devices, the starter lever is released and returns to the starting position, carrying with it the field rheostat lever. Fig. 5 shows the "off" position of the controller equipped with underload release, and Fig. 6 shows an operative position of a controller equipped with both underload and overload release.

NEW RECO FLASHER.

After many years of experimenting, the Reynolds Electric Flasher Manufacturing Company, of Chicago, has placed on the market an electric sign flasher for controlling circuits of from ten to one hundred amperes. It is made with one, two, three, four, five, six or more double pole switches having a capacity of 15, 35, 50, 75 or 100 amperes each; thus from fifty to five hundred four-candle-power lamps may be flashed on and off with one switch, and as many switches can be added as desired.

The switches are controlled by cams which close them automatically in any desired sequence or combination. With this flasher,

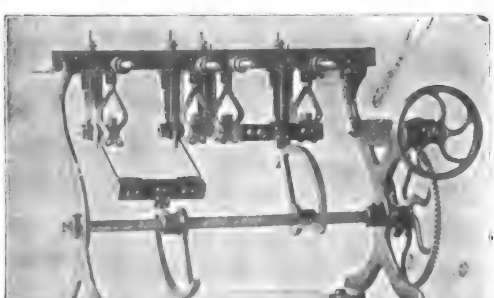

FIG. 7.—RECO FLASHER.

electric signs can be flashed as a whole; double-faced signs flashed alternately, each sign as a whole; or on signs containing a number of words or lines, each word or line can be flashed separately, then all at once. Its mechanical and electrical construction is simpler, it has fewer working parts and is heavier and more substantial than any flasher before produced by this company. Its construction also avoids the multiplicity of circuits running through the flasher, as the division of circuits can be made at a cut-out box located in the circuit between the sign and the flasher. The switch jaws are provided with automatic lubricators in the shape of grease cups or pockets, as shown in the accompanying illustration. These hold sufficient grease to keep the sliding contacts perfectly clean and well lubricated for weeks without refilling. The switch blades drop from the jaws by gravity aided by a spring as they are released by the cams, thus insuring an instantaneous break and avoiding undue arcing. The blades as well as the jaws are made of the best grade of switch copper. Reco flashers are very simple to connect to signs as they are simply cut in between the sign and the service and can be quickly installed to control signs that are already up.

NEW DUNCAN WATT-HOUR METER.

The direct-current watt-hour meter, built by the Duncan Electric Manufacturing Company, of Lafayette, Ind., like other electrical apparatus, has been the subject of marked improvements during the past year.

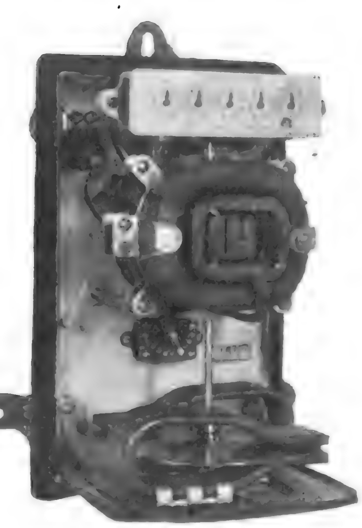

FIG. 8.—DUNCAN WATT-HOUR METER.

Figs. 8 and 8A show the latest form of this meter. The series field coils are machine wound, then thoroughly taped to insure perfect insulation. The manner in which they are clamped to and held on their supporting rods is clearly shown in the illustrations. The armature is wound with 10,000 turns of No. 41 magnet wire and herein lies the meter's superiority to previous direct-current meters; its torque is from 20 to 25 per cent higher while it does not consume as much energy as the older types. The retarding magnets are put through an artificial ageing process requiring six months, and by the time they are put into the meter, they are fully guaranteed not to lose strength, even in the presence of strong external fields. This quality, it is stated, enables the meter to maintain its accuracy indefinitely and prevents any change in its characteristic after being calibrated at the factory. The retarding disc is made from the purest aluminum obtainable and is accurately weighed and balanced before being assembled.

An improvement which undoubtedly appeals to meter engineers and central station managers is the "visual" bearing and "threadless" jewel post of the Duncan meter. The detachable spindle point may be taken out and inserted again without the slightest inconvenience, and without any special tools. The "threadless" jewel post, as the name implies, is without threads; it is held firmly in position by a wire spring, and its insertion or removal requires but a moment. To prevent the brushes from getting out of alignment, they are mounted upon a suitable moulded lava support and, being firmly fastened, their tension upon the commutator is maintained constant, as well as the point of contact. No part in the make-up of a commutator meter is productive of more trouble than the commutator itself. The Duncan Electric Company has made numerous experiments during the past two years in an effort to produce an alloy that would be free from the troubles to which commutators of direct-current motor-meters have been subject ever since their adoption; the result is a composition which is said to be untarnishable, so that the commutator does not turn black after being in service for a short time.

In order to overcome the friction of the bearings and enable the meter to measure accurately very small loads, the compensating coil is rigidly secured within the front series field coil, in close proximity to the armature, and its torque effect upon the armature is adjusted by cutting in or out of circuit a portion of the turns comprising it. The terminals of the various groups of turns of the coil are connected to the contacts of the button switch shown in Fig. 8 just beneath the field coils, by means of which the strength of the compensating winding may be properly adjusted. The advantage of this arrangement over the no pushing in or out of a loose compensating coil, which changes its position every time an attempt is made to fasten it, is obvious.

The binding posts in the Duncan meter are fire-proof, no wood or other combustible material being employed; the mount is of a specially prepared insulating fibre treated with tungstate of sodium. The appearance

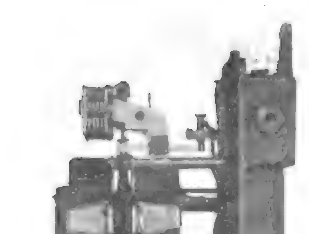

FIG. 8A.—DUNCAN WATT-HOUR METER.

of the meter is particularly pleasing since its finish is that of a semi-dull hard rubber black with the name plate silvered. The dials are unusually large, made of porcelain, and calibrated to read direct in kilowatt hours without the application of any "constant" whatever. The cover is removable

from the front, thereby permitting the meter to be installed quite close to the ceiling. It also fits closely into a felt lined groove and is said to be absolutely dust- and insect-proof. By way of testing the dust-proof qualities of the meter, the makers installed one of them in a flouring mill eleven months ago and upon being inspected three weeks ago, it was found to be as clean and free from dust within, as when first installed.

WESTINGHOUSE OIL CIRCUIT-BREAKERS.

The Westinghouse Electric & Manufacturing Company has brought out a new automatic oil circuit-breaker, known as electrically-operated Type E, adapted to distant control work and designed for voltages from 3300 to 25,000. The circuit-breaker is made in single-pole units, each being mounted apart from the switchboard in a brick or concrete compartment. Two, three and four-pole combinations are made by placing the units side by side. The base of each unit is of treated soapstone and holds two heavy porcelain insulators which carry the stationary contacts and the connection to the external circuit. The movable contacts are at the ends of a U-shaped metal casting fastened at the center to a rod of treated wood, which is moved up and down by the operating mechanism in closing or opening the circuit. The final arc on breaking the circuit is taken by an arcing tip which may easily be replaced. The movable contacts are in the shape of truncated cones and fit into corresponding surfaces in the stationary contacts which are made up of a number of copper springs. This arrangement gives a large area of contact, and is claimed to insure a positive contact over its entire surface, and entirely prevent "freezing" under any condition of overload. The tanks are liberally insulated and the inner surface so shaped as to reduce the amount of oil required, and therefore the fire risk, to a minimum. The open position is in all cases maintained by gravity. A simple system of levers and toggles is mounted on the top of the base and a powerful iron-clad solenoid is arranged with its movable core so attached to the lever system that when the magnet is energized the circuit-breaker will be closed. The standard voltage used on the solenoid is 125 volts. A second electro-magnet acts as a tripping coil and may be controlled by a relay of any desired type. A small single-pole, double-throw switch is mounted on the base and is operated by the motion of the levers in opening or closing this circuit; it controls the tell-tale indicator and lamp which are mounted in view of the operator. The entire mechanism is extremely compact and solid in construction, while the insulation has been carefully provided for. As in other Westinghouse oil circuit-breakers, the break takes place near the surface of the oil instead of at the bottom where there is almost always a certain amount of sediment. These circuit-breakers have no live parts exposed. The oil tanks are firmly held in position by special holders, which, by the simple movement of a lever, may be removed and all contacts examined without disturbing any other part of the circuit-breaker.

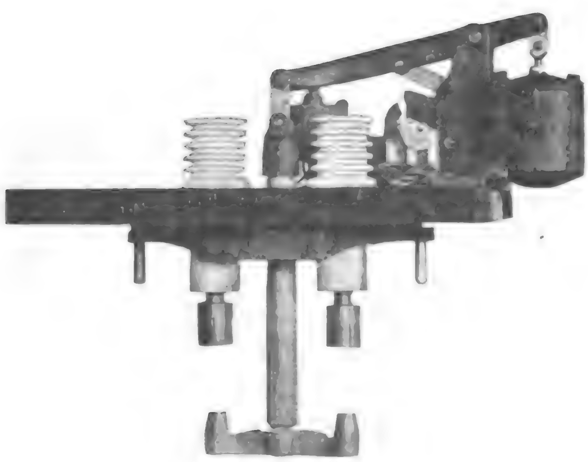

FIG. 9.—WESTINGHOUSE OIL CIRCUIT-BREAKER.

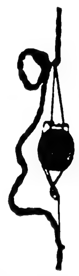

FIG 10.

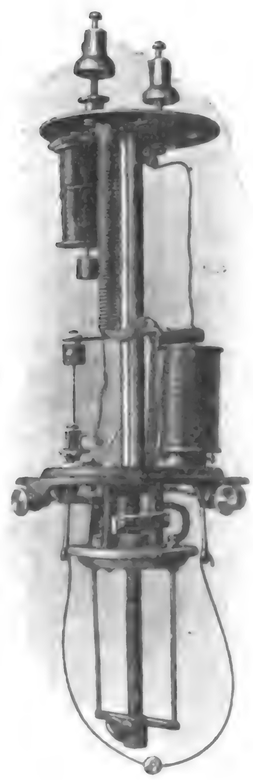

FIG. 11.—WARNER ARC LAMP.

NEW CORD ADJUSTER.

The Marshall Electric Manufacturing Company, of Boston, has brought out the new form of cord adjuster shown by Fig. 10 herewith. The adjuster is intended for use where such adjusters as the Dow are not required. The device does not roll up the cord like the Dow adjuster, but it can be worked by hand, and will doubtless be found satisfactory for many places.

THE WARNER ARC LAMP.

Fig. 11 herewith shows the Warner enclosed arc lamp made by the Warner Arc Lamp Company, of Muncie, Ind. The lamp differs from the usual enclosed arc lamp in that it operates on the shunt principle of control, whereas most arc lamps operate on the differential principle. In the series enclosed arc lamp the carbons are fed in a way which is said to be strictly electrical, the shunt having no connection or control over the series magnet in a mechanical way. For this reason the lamp has but a very small number of parts. There are, the manufacturer says, no springs or multiplicity of rods, levers, dash-pots, pivots etc., nor joints about the lamp to become corroded or stick. The globe cap is made in one piece, and that of an insulating material which is both a non-conductor of heat as well as of electricity so that insulating bushings are not required in supporting the lower carbon holder from the gas cap. The gas cap of the lamp being also an insulator, no additional insulator is required at these points. The gas cap is made large, and is mounted at a suitable distance below the frame of the lamp so as to allow a current of air to go up through the opening at the bottom of the outer globe and circulate around the inner globe, keeping it cool, and over the gas cap between it and the bottom of the lamp, thereby dissipating the heat of the arc and preventing it from entering the lamp body, and raising the resistance of the shunt and series coils. A peculiarity of the lamp is the use of an open bottom outer globe. The lamp is quite light, weighing only 19 pounds with globes complete. The same principle involved in the direct-current series enclosed lamp is also being carried out in the other lamps being brought out by the company. The results are said to be very apparent in the alternating current lamps, the tendency to vibrate and chatter, it is claimed, being obviated. The current in the multiple lamps is said to constantly reduce from the time it picks up until it feeds, often resulting in a variation of from 5 amperes at pick up on 110 volts to one ampere at the time of feeding. The result is said to be a saving in the current consumption, and a slight variation in the amount of light furnished, because as the current is reduced the arc is lengthened and the power lost in the resistance reduces until it reaches a minimum, which the manufacturer claims often falls as low as 20 watts on 110 volts.

NEW BOOKS.

MODERN PRACTICAL ELECTRICITY. By R. Mullineux Walmsley. Chicago: W. T. Keener & Co. Cloth; 4 volumes; 1200 pages, total, 7 ins. x 10 ins.; 1208 illustrations. Price, $12.00.

The title of this rather ambitious work is a misnomer; it might appropriately be entitled a history of the development of electrical apparatus up to 1900, with the equations of fundamental laws and descriptions of interesting antiquities. Very few really modern applications of electricity are described, the first three volumes being devoted to historical matter and descriptions of obsolete apparatus—not merely obsolete to the ordinary degree characteristic of apparatus abandoned a few years ago but so far out date as to be entirely unfamiliar to the present generation of engineers so far as the actual machinery is concerned. It seems a pity that the author should have

so misapplied his technical knowledge, which is evidently not lacking. While the books are extremely interesting and contain a sprinkling of useful information, the latter is such a small proportion of the whole, and therefore so hopelessly buried, that the work has no practical engineering value.

"MECHANICAL WORLD" POCKET DIARY AND YEAR BOOK, FOR 1905. Manchester, Eng.: Emmott & Co., Ltd. Buckram; 333 pages, 4 x 6 ins.; 66 illustrations; numerous tables. Price, 6d.

This is the eighteenth edition of this highly meritorious little reference book, and it shows evidence of careful revision. There have been added tables of the squares, cubes and fourth powers of fractions, trigonometrical ratios, powers and roots of useful factors and sheet and hoop iron gauges. The section on ball bearings has been revised and a table added which gives the relations between ball diameter, number of balls and diameter of ball circle. A short section on the speed and power of small launches has also been added.

FOWLER'S ELECTRICAL ENGINEERS' YEAR BOOK. Manchester, Eng.: Scientific Publishing Company. New York: D. Van Nostrand Company. Boards or leatherette: 600 pages, 3¾ ins. x 6 ins.; 80 illustrations; numerous tables. Price, boards 75c.; leatherette, $1.00.

This is the 1905 edition of Mr. Fowler's well-known pocket book for electrical engineers. It has been carefully revised and somewhat enlarged. Among the new material may be mentioned additions to the sections on parallel operation of dynamos, management of dynamos, types of electrical measuring instruments and their use, electrical distribution, storage batteries and electric traction. The section relating to alternating-current working has been extensively revised and improved. An error on page 156 remains uncorrected; in the formula for maximum allowable number ampere-conductors around the periphery of the armature of a multipolar dynamo, the co-efficient 288 should be 144, in order to make the equation consistent with the one for bipolar machines. We have pointed out this error twice before. The book is excellent, however; it is impracticable to eliminate errors in one of this class.

HUGE ELECTROMAGNETIC CONTROLLERS.

The Electric Controller & Supply Company, Cleveland, Ohio, has just shipped the second of two 200-h.p., 220-volt magnetic-switch controllers to the Lorain plant of the National Tube Company. These controllers are for reversing motors driving the tilting tables on each side of the plate mill. They give automatic acceleration, which can be adjusted to the maximum rate consistent with safety to motor and gearing.

When reversing from full speed forward to full speed reverse, the table is automatically brought to a quick stop and accelerated in reverse direction in the least time interval consistent with safety. The magnetic controller, with its resistance bank is placed near the motor, thereby effecting economy in the use of heavy connecting wire. The operating controller consisting of a small master switch, is conveniently mounted on the roller's "pulpit," and since the contacts of this controller carry only a small current, it may be operated with ease, and the connecting wires are small. The construction of the magnetic controller is such that no matter how rapidly the operating controller may be reversed, the current to the motor is automatically limited to a safe value.

LARGEST GAS-ENGINE-DRIVEN GENERATORS IN THE WORLD.

The California Gas & Electric Corporation, San Francisco, Cal., has just placed an order with Crocker-Wheeler Company for three 4000-h.p. three-phase revolving field alternators, to be driven by 6000-h.p. gas engines to be built by Snow Steam Pump Works. These generators will be the largest in capacity in the world driven by gas engines, and will furnish power to operate the United Railroads of San Francisco, in accordance with a contract recently secured by the California Gas & Electric Corporation. The Snow gas engines, to which they will be direct-connected, are the largest in the world for this class of service. They will run at 83 r.p.m., and the generators will deliver 13,200 volts at 25 cycles. The installation of these three engine-driven generating units in San Francisco will mark an important step for the transmission company, as they will operate in parallel with the water power plants of the company, and thus serve as an important reserve plant for the entire system. One of the units will be used exclusively for handling the peak load on the railway lines.

The securing of this contract by the Crocker-Wheeler Company indicates that the important position this company has held in the direct-current field is also to be maintained in the alternating line.

CUTLER-HAMMER EXPANSION.

The Cutler-Hammer Manufacturing Company, Milwaukee, is building a three-story addition to its factory which will add 50,000 square feet of floor space to the plant. The construction is of the slow-burning type, and it is expected that the addition will be ready for occupancy this month. The building will be equipped with the Grenelle system of sprinklers, will be heated by the Paul system and lighted with mercury vapor lamps. The fire-service storage tank, with a capacity of 75,000 gallons, will be located under the boiler room, and the fire pump will have a capacity of 750 gallons a minute. The power plant for the entire factory will be in the new building, and will be up-to-date in every respect.

As soon as this building is completed work will begin on an addition to the present office building to which another story will be added. The third floor of this building will be entirely devoted to the engineering department, while the superintendent, chief of the engineering department, cost department, publicity department and a part of the accounting department will occupy the second floor. The executive offices and the rest of the accounting department will be on the first floor as at present.

The works of the Cutler-Hammer Manufacturing Company now occupy an entire block, with the exception of a small plot on one corner. Recently this company purchased a plot of ground on St. Paul Avenue, opposite its factory, upon part of which a brass foundry has been erected. Upon the remainder of this property buildings will be erected during the coming year for storage and factory purposes.

THE RECORD RUN OF THE WESTINGHOUSE EXPOSITION TURBINE.

A memorable incident of the morning following the close of the St. Louis Exposition was the formal shut-down and inspection of the 600-h.p. Westinghouse steam turbine generator unit in the Palace of Machinery after a continuous run of over 3962 hours—a performance which has had no parallel in steam turbine work. This machine was started on its long run at 9.20 o'clock on the morning of Monday, June 20, shortly after its installation at the Fair, and was stopped at 11.32 o'clock on the morning of Friday, December 2. During the five and a half months that the unit was in operation it supplied current for light and power throughout the Westinghouse exhibits in the Palaces of Machinery, Electricity and Transportation. Mr. Charles F. Foster, chief operating engineer of the Exposition; Mr. H. M. Holman, supervising engineer at the Government Exposition gas-engine tests, and a number of Westinghouse representatives, including Messrs. Wallace Franklin, of Detroit, C. C. Chappelle, of Chicago, and W. K. Dunlap, managing director of the Westinghouse exhibits, were present when the turbine was stopped. It was found to be in perfect condition, and there were no signs of wear, the bearings still retaining the tool marks as they had come from the shops.

There have been at least two instances on record in America in which reciprocating engines have been run continuously for about the same length of time as that of the record run of the Westinghouse turbine. The remarkable feature of the turbine run, of course, was the maintenance under load of a speed of 3600 revolutions a minute for such a long period. From 8.30 o'clock in the morning to 10.30 o'clock in the evening, every day of the run, the load carried varied from 75 per cent of full load to 25 per cent overload. The total number of revolutions almost touched the billion mark—855,792,000.

THE BUSINESS SITUATION AT THE CLOSE OF 1904

WM. NUGENT & CO., Chicago, Ill.—We have found it necessary to equip our shops with more machinery and engage more men in order to fill our orders.

S. J. STEWART, New Orleans, La.—I have done 50 per cent. more business this year (1904) than last, and the prospects for 1905 seem to be as good if not better.

KNAPP ELECTRIC AND NOVELTY COMPANY, New York City, N. Y.—We find a most satisfactory increase in sales, general conditions good and the outlook for 1905 extremely bright.

THE CRESCENT INSULATED WIRE & CABLE COMPANY, Trenton, N. J.—We are very busy in our Insulated Wire Department, and the prospects for the coming season are very bright.

CROUSE-HINDS COMPANY, Syracuse, N. Y.—Our fiscal year closed July 1, consequently we are not able to say very much at this time. We believe, however, that the outlook for business is fine.

W. S. HILL ELECTRIC COMPANY, New Bedford, Mass.—Our business has never been so good before, and it seems from the general tone as if the present brisk demand for material would continue.

THE FIDELITY ELECTRIC COMPANY, Lancaster, Pa.—We find the prospect for our electrical business for the coming year most favorable. At present we have orders booked to run us three months.

THE DERRY-COLLARD COMPANY, New York City, N. Y.—While the past year has been below par in the book business, there is a decided improvement at present, and prospects for an exceptionally good year for 1905.

AMERICAN DE FOREST WIRELESS TELEGRAPH COMPANY, St. Louis, Mo.—The development of our system during the past year has been very satisfactory, and has exceeded the most optimistic hopes of its friends.

THE KESTER ELECTRIC MANUFACTURING COMPANY, Chicago, Ill.—The closing year has been a very prosperous one for us, business being such as to necessitate running our factory night and day for over three months.

KRAUSHAAR BRASS MANUFACTURING COMPANY, St. Louis, Mo.—The business conditions as we have found them during the past year have been exceedingly good, and present prospects point to a very busy coming year.

ENGBERG'S ELECTRIC AND MECHANICAL WORKS, St. Joseph, Mich.—Our business for 1904 has been by far the best in our experience. We were obliged to take larger quarters because we were unable to keep up with our orders.

LIBERTY MANUFACTURING COMPANY, Pittsburg, Pa.—The volume of business for 1904 was, on the whole, very satisfactory, our business having increased in spite of the general business depression. The outlook for 1905 is very encouraging.

THE VAN DORN-ELLIOTT ELECTRIC COMPANY, Cleveland, O.—We have no complaint to make as to business during the past year. The outlook for next year, however, is considerably brighter than it has been during the past year.

GEORGE W. LORD COMPANY, Philadelphia, Pa.—In spite of the presidential election, 1904 has been the most prosperous in the history of this concern, both domestic and export business showing a marked and very satisfactory increase.

NEW ENGLAND COIL WINDING COMPANY, Atlantic, Mass.—The year 1904 has been the most profitable year of our existence. With the addition of several new winding machines, now in process of construction, we propose to make 1905 eclipse the past year.

THE NEW ERA GAS ENGINE COMPANY, Dayton, Ohio.—Our business has been very good this past year, and prospects for 1905 are very flattering indeed. We were busy during the summer months when some factories were complaining of dullness.

THE FRANKLIN ELECTRIC MANUFACTURING COMPANY, Hartford, Conn.—Our business during the past year has been very satisfactory, and we look for an increased volume during the coming twelve months.

CROCKER-WHEELER COMPANY, Ampere, N. J.—We expect a prosperous season in the coming year. Business appears to be reacting from the depression of the last few months, and more and more purchasers of electric generators and motors are entering the market.

BUCKEYE ENGINE COMPANY, Salem, Ohio.—Our business for 1904 so far (up to December 15) amounts to about 70 per cent of that for 1903. We have operated our plant with a full day force and on full time. Prospects for the coming year are for an increased business.

BROWN CORLISS ENGINE COMPANY, Corliss, Wis.—Business has improved very materially in the past sixty days. We now have on our books over $190,000 worth of work, and have a great many quotations outstanding on work which promises to come our way.

ELECTRIC MACHINERY COMPANY, Minneapolis, Minn.—The last twelve months have been quiet as compared with a few years previous, but the outlook for the coming year seems better, and business will, we believe, show marked improvement over the year that has just closed.

FLEMING SLATE COMPANY, Erie, Pa.—Things look very bright in the electrical line, and already good orders are coming in. This company has moved its general offices from Poultney, Vt., to Erie, Pa., where all communications should be addressed. Mill and quarries at Poultney, Vt.

E. D. DRAKE & CO., New York City, N. Y.—We have no fault to find with trade conditions, and the outlook is good. The conduit manufacturers are in the midst of a silly war of prices that benefits no one and injures us all, but common sense will soon prevail again and our business promises well.

AMERICAN BRAKE SHOE & FOUNDRY COMPANY, Chicago Ill.—Since the election our orders show a decided improvement in several lines, although they have been a little light previous to this. We are turning out a very satisfactory tonnage of low carbon steel castings for motor and dynamo work.

AMERICAN ENGINE COMPANY, Bound Brook, N. J.—Our experience and observation has been that 1904 has been been a poor year, but since the first of October there has been a marked improvement in the amount of business offered, and we think the prospect is extremely encouraging for next year.

MUTUAL ELECTRIC & MACHINE COMPANY, Wheeling, W. Va.—We have found that business has greatly improved in the last three months, and the demand for our product seems to be increasing very materially, especially throughout the East and on the Pacific Coast. Business in the main is very satisfactory.

THE GREEN FUEL ECONOMIZER COMPANY, Matteawan, N. Y.—Although we have not done as much business in the past year as we did in 1903, our business in the electrical field was satisfactory, and from the inquiries received and work that we have on, our business in that field for 1905 looks very promising.

THE CHICAGO RAWHIDE MANUFACTURING COMPANY, Chicago, Ill.—The past year has been the largest and best we have ever experienced. We find the demand for goods in our line of manufacture is steadily increasing, and feel confident that the coming year will be at least as prosperous as 1904 has been.

MILTON F. WILLIAMS MANUFACTURING COMPANY, St. Louis, Mo.—Our business in the past year has been very good, and the future looks exceedingly bright. We do not manufacture electrical machinery, and are not particularly interested in electrical appliances; we refer entirely to the crusher business.

WARNER ARC LAMP COMPANY, Muncie, Ind.—Trade has been exceedingly good during 1904, orders coming in almost every day from all points of the compass for Warner lamps. We are expecting the next twelve months to be even better than the year just passed; at least, the outlook seems to warrant this conclusion.

MOLINE INCANDESCENT LAMP COMPANY, Moline, Ill.—Our business is increasing at a very rapid rate. October business was 106 per cent. over the previous month; November, 90 per cent. over October, December starting in to show an increase over November of possibly over 60 per cent. The outlook for business with us is good.

THE CUTTER ELECTRICAL AND MANUFACTURING COMPANY, Philadelphia, Pa.—While our business has not been as good as it was in 1903, the volume

has been entirely satisfactory. The outlook for the future was never better. We are just about increasing our factory space 50 per cent., and we fully expect to have use for all of it.

THE MERIAM-ABBOTT COMPANY, Cleveland, Ohio.—Our business prospects are such that we are preparing to increase our output and also to build much larger engines. There is a very promising outlook in the field of direct-connected generating sets, and we are putting in a number of plants for lighting office buildings and private residences.

THE ELECTRIC STORAGE BATTERY COMPANY, Philadelphia, Pa.—Sales during 1904 of the batteries manufactured by us have been satisfactory. New applications of batteries are constantly developing, and their use in what may be termed the standard applications is growing. We consider the prospects for the coming year excellent.

GREEN ENGINEERING COMPANY, Chicago, Ill.—In our opinion the business situation is in better shape now than it has been for a long time, and we anticipate doing a larger business in 1905 than during the preceding year. We are very well satisfied with the past year's business, and especially so since the election, having closed twelve contracts since that time.

THE STERLING ELECTRICAL MANUFACTURING COMPANY, Warren, Ohio.—We have found business in the main during 1904 fully as voluminous as in 1903, but without any noticeable increase. From all appearances the year 1905 will be a bumper, and we look for from 25 to 30 per cent. general increase in the demand for incandescent lamps over the past year.

THE FOOS GAS ENGINE COMPANY, Springfield, Ohio.—Business with us is heavy and prospects never better. We have during the last year considerably increased our facilities, but the plant is still taxed to the utmost. Our agents without exception advise us that we will have to work harder than ever before to keep up with their demands during the coming year.

THE ROBBINS & MYERS COMPANY, Springfield, Ohio.—The business of our last fiscal year, which closed September 30, was the best in the history of our company. While it is difficult to predict for the future, we are inclined to think that business will be found to continue on a healthy basis; as for ourselves, we are looking forward to a better year than last.

CLEVELAND ARMATURE WORKS, Cleveland, Ohio.—The last year's business has been the largest in our history, and we are making preparations for handling a greater volume next year, and see no reason why we should be disappointed in our expectations, but our business being that of electrical repairs, is not a particularly good one from which to judge the pulse of trade.

THE C. & G. COOPER COMPANY, Mt. Vernon, Ohio.—We have had a large amount of business during the past year. We have just completed an extensive addition to our new machine shop, which is in full operation. Large orders for Corliss engines have been received in recent months, so that we are now working day and night to meet the demands of our increasing trade.

A. ROE & CO., New York City, N. Y.—Our specialty is the design and construction of power plants and lighting systems, in which we have been very busy, principally on preliminary work, there having been of late much difficulty in financing enterprises of this nature, except in the large cities. At present there are good indications of a busy spring along all lines of construction.

KEYSTONE LUBRICATING COMPANY, Philadelphia, Pa.—We have been doing an increasing business, month by month, during the whole year, and every month in this year has exceeded from 25 to 50 per cent. the corresponding month of 1903. Our business is still increasing, and for 1905, if business comes in as it promises now, we expect to do twice the business that we have done in 1904.

STANDARD UNDERGROUND CABLE COMPANY, Pittsburg, Pa.—We found the business conditions surprisingly good in our lines during 1904, considering the fact that it was a presidential election year. Business has increased very materially during the last month, and we consider that the future prospects of our own and the electric business generally are very good indeed.

RIDGEWAY DYNAMO & ENGINE COMPANY, Ridgeway, Pa.—We had a good year's business, with our factory running full time, but have found during the last month or six weeks a less active market. We look for a prosperous year for 1905 but hardly expect that buyers will be placing their orders till the spring is well advanced and the weather will permit construction to begin.

FARR TELEPHONE & CONSTRUCTION SUPPLY CO., INC., Chicago, Ill.—The telephone business for the year 1904 was about up to the standard of previous years for the first six months of the year; after that there seemed to be a steady decline in trade up to election time. We notice a marked improvement in our business since election, and indications are pointing to a very heavy business for 1905.

AMERICAN WATER SOFTENER COMPANY, Philadelphia, Pa. — Although business conditions as we have found them during the past year, have been somewhat dull, we have been able to do a constantly increasing business. Since September 1 trade seems to have improved considerably, and present appearances are that we will have an increase of business with the first of the year that will tax our abilities.

THE R. M. CORNWELL COMPANY, Syracuse, N. Y.—During the past year our business has increased over 100 per cent. The automobile business, which we took on about one year ago, has turned out very much better than we expected. We sold over 100 machines in all. Our dynamo and motor sales for the past year have been more than doubled. In our supply department, business has never been better.

ELECTRICAL APPLIANCE COMPANY, Chicago, Ill.—The year just closing has been a disappointment to us in the volume of business and net results, and we believe this condition has been quite general in the electrical trade, and more or less general in other lines. However, we consider the outlook for 1905 to be very favorable, and are looking forward hopefully for a material improvement in business conditions.

THE PHILADELPHIA ELECTRICAL AND MANUFACTURING COMPANY, Philadelphia, Pa.—With the exception of the months of June and July of 1904, we have been extremely busy. For some time we have been as much as three months behind orders for certain goods, and from the business and inquiries that we are receiving we have every reason to believe the outlook for the future to be exceedingly good.

THE LAGONDA MANUFACTURING COMPANY, Springfield, Ohio.—The past year has been a very busy and successful one with us, and our trade has steadily grown, although along in latter part of September and October, it seemed a little dull. Since then, business seems to have taken somewhat of a boom, and we have been busier than ever before in our history. As far as we can determine, the outlook is very favorable.

HENRY H. HUMPHREY, St. Louis, Mo.—Business is very good at present, and the prospects for the new year are most encouraging. During the last year, particularly while the World's Fair was in progress, business has been exceptionally quiet in building and engineering work, as far as my experience and observation have gone With the closing of the successful Exposition and the outcome of the election, the outlook is very much brighter.

D. M. STEWARD MANUFACTURING COMPANY, Chattanooga, Tenn.—Our business in 1904 shows considerable increase over 1903. The business of September, October and November, 1904, was almost double that of the same months last year. We now have more unfilled orders on file than ever before at the same time of the year. We believe that 1905 will be a splendid year for electrical business, and are preparing to take care of an increased trade.

ELECTRICAL TESTING LABORATORIES, New York City, N. Y.—Our business has increased noticeably since the election, and our prospects for a continuance of the present rate of increase seem good. Our business was much better during the months of August and September than during October. Whether the slump preceding election was due to that cause or not we cannot say, but the improvement immediately after election was marked and still continues.

THE HOLTZER-CABOT ELECTRIC COMPANY, Brookline, Mass.—Although we have continued to run full time and with practically a full force throughout the past year, yet we have felt to some extent the general lull in business. November has

shown quite a marked increase in inquiries and orders, and the indications point to a general revival of business. We will be very much surprised if the coming year does not prove to be a very busy one in the electrical industry.

DE LAVAL STEAM TURBINE COMPANY, Trenton, N. J.—We found business conditions during the past year very fair, and since September have noted a decided improvement, and consider the outlook in our line encouraging.. It might be of interest to note that since the latter part of 1901, when we commenced work, we have built 297 steam turbines, 146 of which are driving electrical apparatus, 95 driving centrifugal pumps, 32 driving fans, and 24 other purposes.

MARSHALL ELECTRIC MANUFACTURING COMPANY, Boston, Mass.—Our business for the past year has been fully up to the average, and during the autumn months there was a decided increase over any previous year since we have been in business. Inquiries, too, are more numerous than for a long time, which indicates that people using our goods are contemplating still further activity in the near future; we, therefore, look for an exceptionally good business during the coming year.

PENBERTHY INJECTOR COMPANY, Detroit, Mich.—Although business conditions have been somewhat unfavorable during the past year, we have noticed a marked improvement in business during the past sixty days, and in our judgment the coming year should be one of exceeding prosperity. We cannot speak with any knowledge concerning the electrical business, as we do not come into close touch with that line, but as regards the steam supply trade, we believe 1905 will be a banner year.

CHASE - SHAWMUT COMPANY, Newburyport, Mass.—We have found the electrical manufacturing business during the past year very poor up to the latter part of September. However, within the last two or three months a marked improvement has been noticeable, certainly in our lines. We think that the business of the coming year will, without doubt, be the largest that has ever been seen in this line, due largely to the fact that the improvements on our goods have been rapid and quite marked.

THE TRIUMPH ELECTRIC COMPANY, Cincinnati, Ohio.—Business during the past year has not been equal to what it was for three or four years back. However, during November business picked up with us materially; in fact, we did more than in any two previous months during the year. This was also true of December. The outlook for the coming year is quite promising. Judging from present reliable indications, we believe that after the early spring we will all have about as much as we can attend to.

HAPGOODS, New York City, N. Y.—The year just closed was one of unusual prosperity. The number of our offices has been increased to a total of twelve, thoroughly covering the entire country. Favorable conditions in all lines of business have created an unusual demand for men; inquiries from electrical companies have been particularly numerous, and men have been supplied for positions in the executive, advertising, accounting and other departments, as well as in the drafting and engineering branches.

I. P. FRINK, New York City, N. Y.—During the past year our trade has held steady in the electrical jobbing centres, and where store improvements, according to trade reports, have been greatest. We are of the opinion that the coming year is going to disappoint those who are not prepared to handle more business. The reports which we have of buildings in progress and contracts let for operations to be started in the spring satisfy us that there will be many opportunities for manufacturers to sell high grade equipment.

THE TETER-HEANY DEVELOPING COMPANY, York, Pa.—We began business on June 1, 1904, at which time we found business very dull. It continued to be so during the greater part of the summer, but about the middle of September began to brighten up, and it has been improving ever since. After October 1 we were rushed with orders, and business has been increasing rapidly within the last month. We feel so sure that it will keep on doing so, that we may move into larger quarters this spring.

JAMES L. ROBERTSON & SONS, New York City, N. Y.—We have had a fair amount of business during 1904—not near so much as in either of the previous two years, but enough to warrant us in believing we have had our share. We are not with those concerns who report a noticeable improvement since the election, but we feel sure there is before us (for at least four years) a *good, healthy* condition of business, and so strong are we in that belief we will "mortgage the farm" if necessary to secure a good-sized share.

STURGESS GOVERNOR ENGINEERING COMPANY, Watervliet, N. Y.—We have found business extremely satisfactory in the past twelve months. The greater part of the year we have been obliged to work day and night shifts, but lately, owing to an addition of about 60 per cent. to our building, we have been enabled to get along with the day force which numbers the same as the day and night forces did formerly. We have more than doubled our business in the past year, and prospects are very bright for the future.

MARINETTE GAS ENGINE COMPANY, Chicago Heights, Ill.—Since the recent election we are experiencing a large and active increase in not only orders but substantial inquiries from all parts of this country, and many foreign countries, particularly for gas engines to be installed in connection with electric lighting plants. We have booked orders during the past two weeks, which, in volume of business, aggregate more than we have received in the preceding three or four months and from present indications we anticipate a very active and prosperous year.

FITCHBURG STEAM ENGINE COMPANY, Fitchburg, Mass.—We have had all the work we could do for the past year, although it has taken harder work to get orders than it did the previous year. We have now two or three months' work ahead, and inquiry is very much larger than it was three months ago. The prospect of the engine and electrical business we think is first-class for the coming years. We are fortunate, however, in that there has been no time during the last twenty years when we have not been running full time, and usually with a good deal of work ahead.

THE VOUGHT-BERGER COMPANY, La Crosse, Wis.—We have no complaint to make relative to our business during the year 1904. The appearance of rust on the crops in Northwestern Minnesota and the Dakotas interfered with the building of farm lines in that territory, but in spite of this, trade conditions in the Northwest during 1904 were better than the year previous. The telephone business in the South and in the far West is showing splendid advances. The first ten days of December brought us heavier business than any previous period at this time of the year.

SMITH & HEMENWAY COMPANY, New York City, N. Y.—In view of the large improvements going on in the electrical world and the many inquiries that we are receiving for electrical tools, we think that 1905 will be one of our banner years. We have noticed a perceptible improvement in the quality of goods ordered by the electrical construction companies. Formerly, it was a question of price with them; anything that would do the work. To-day they look into the merit of an article very thoroughly before purchasing. We are looking for a big business, and are preparing to take care of it.

JOS. E. LOCKWOOD, Detroit, Mich.—As my present business as sales agent of the Bullock Electric Manufacturing Company, Allis-Chalmers Company and the Electric Storage Battery Company, began about May 1, 1904, I am not, of course, in position to judge of the normal demands in the lines I represent during the first year, but I have found a fair demand existing in the three lines I represent from the beginning. During the last sixty days, however, inquiries and actual orders have increased steadily, and the amount of desirable business now in sight is much greater than at any previous time during this year.

THE AUTOMATIC ELECTRIC COMPANY, Chicago, Ill.—We have enjoyed a most prosperous and satisfactory year. We have equipped within the past twelve months nearly fifty exchanges with automatic telephone equipment, and have built and installed additional apparatus for large exchanges, which were put in service in 1903, and we have completed and put in service exchanges which were begun late in

1903. We have had a splendid year, and are looking forward to a still better one. For 1905 we have about a million dollars' worth of orders on hand. We are running our plant full capacity, and are working overtime on pending orders.

THE BANNER ELECTRIC COMPANY, Youngstown, Ohio.—The volume of business done in each month of the past year has shown a very satisfactory increase over the corresponding month of the previous year, and up to this time the average percentage of increase in the volume of business transacted this year, as compared with last year, is approximately 37 per cent.; this applies to actual shipments. Business in almost every line has shown marked improvement within the last two months, and we believe that we are just entering upon an era of unprecedented good times, and the electrical business generally will certainly participate largely in the general prosperity.

THE PLATT IRON WORKS COMPANY, Dayton, Ohio.—This company had on January 1, 1904, sufficient orders to insure the operation of its entire force and equipment for the ensuing four to five months, consequently the alleged diminution in volume of trade was not in evidence until the months of June and July. We have had a diminished trade because the erection of contemplated power plants has been deferred, but we approach the new year with abundant confidence, basing our conviction upon the fact that there has been a marked increase in trade during the past sixty days, although a decrease in orders is always encountered during the fall and winter.

H. W. JOHNS-MANVILLE COMPANY, New York City, N. Y.—Our electrical business has never known a year of such prosperity as 1904. The amount of material turned out from our factories has been far greater than in any previous year, and our entire product has been advantageously placed. The outlook for the coming year in this country, particularly in railway work, bears greater promise of activity than any year within the past decade. Our British and European business also gives us much cause for self-congratulation. Our factories, although improvements and additions have been made constantly, are running at their utmost capacity to handle our orders.

HARRISBURG FOUNDRY & MACHINE WORKS, Harrisburg, Pa.—This company has been exceedingly fortunate, having been able to operate its entire plant day and night without interruption now for five years. Our gross business for 1904 was only 7 per cent. lower than that of the high-water mark years of 1902 and 1903, and prices have been fairly satisfactory. Looking forward to 1905, we find while inquiries for delivery into the next year are numerous, there is a disposition to hold off until business results are determined and prices finally adopted for the future. We can see, however, no reason for not expecting a very large business during the coming year.

CONSOLIDATED ENGINE-STOP COMPANY, New York, N. Y.—Business conditions with us during the past year have not been particularly satisfactory, but as to the future prospects we are extremely optimistic. Soon after election orders and inquiries began to increase, and we have had the largest month so far (up to December 20) that we have had since April, 1904, and we expect a large business in 1905. In addition to the increased number of orders, the most gratifying improvement we have experienced is the increased number of inquiries regarding engine stops from large manufacturers and power companies. We mention this, for heretofore it has been somewhat difficult to interest them in automatic engine stops.

SHEPHERD ENGINEERING COMPANY, Franklin, Pa.—Business during the past year was generally very dull, although there were occasional spurts of activity at various times. This company received a great many inquiries, and on the whole did a very fair business. But the number of inquiries received was out of all proportion to the actual business closed. For some reason or other the majority of prospective purchasers wanted to put off buying until about or after the first of the year. There has been a wonderful improvement, however, during the past six weeks, and more actual business has been booked in this time than there was in any preceding three months of the year. The prospects for 1905 are all that one could desire.

THE LANE & BODLEY COMPANY, Cincinnati, Ohio.—Our experience during the past year (1904) has shown the demand for engines to have improved over the preceding year. This is especially true of the latter half of 1903. A conservatism among buyers has been noticeable throughout 1904. The engines sold seemed to be required more for the extension of established businesses than for new enterprises, which indicates to us a healthful foundation for the future. There seemed to be at no time during the year a disposition to speculate on the future of business, but to fill requirements actually developed. We are quite optimistic in connection with prospects for the year 1905, believing the atmosphere is cleared and there is nothing to prevent the progress and expansion naturally ahead of us.

WILLIAM D. MARKS, Philadelphia, Pa.—During the past year the market for electric railway and light station securities has been open only to the very highest class of going and proved properties, and consequently there have been very few large new enterprises placed in the hands of engineers for construction; on the other hand, many going enterprises have made extensions, and are still making them. For six months the manufacturers of general machinery have had slack shops, and even since the election there has been no sudden and broad revival of business such as has been generally expected. This condition, it appears to me, will not continue, and when constructed becomes possible next spring, I believe there will be many carefully studied enterprises launched, the success of which may be predicted from our experience in the past.

BATES & NEILSON, New York City, N. Y.—Business conditions during the past year have been, comparatively speaking, quite dull. There is, however, a decidedly better tone to the general market at present, and it is to be expected that after the first of the year there will be increased activity. This year's depression in business will have its good effect. Those who successfully weathered the storm are better for their experience to-day, and those who did not pull through were not equal to the task they had undertaken. To-day the conditions are excellent for the upbuilding of business of good, substantial character. For the past three months it has been clear that this state of affairs has been apparent to many, with the result that steel works, manufacturing establishments and contractors throughout the country are taking on men to fill the places of those whom it was necessary to let go last January and February.

AMERICAN AND BRITISH MANUFACTURING COMPANY, Providence, R. I.—Business in general for 1904 has been quiet in all departments. The Corliss Works, at Providence, have shared the exceptional stagnation in steam engine demand due to the general dullness and the waiting attitude of power users to see where the turbine comes in. This combination has produced, perhaps, a record breaker for dullness, but steam engine inquiries have begun to come in freely, and the promise for 1905 is bright. It looks like the beginning of another prosperous period, equaling that recently past. The Diesel engine department has been steadily gaining through 1904. The prospect is for a rapid increase through 1905, with all the demand we can supply before the year ends. Our condenser department is well established, and has a very bright prospect for 1905.

DODGE & DAY, Nicetown, Philadelphia, Pa.—We have had a very prosperous year, regardless of the period of depression which prevailed along some lines prior to the presidential election. Our relations in an engineering capacity with various manufacturers gives us a clear insight into their business, past and prospective, owing to the character of our work, so that it is with some degree of certainty that we say that prospects for the coming year are exceptionally bright. We have been called upon to make a number of layouts contemplating the expenditure of several millions of dollars, which is the best indication we know of that manufacturers are sanguine as to future business conditions. We also know that the inquiries being received by our clients for quotations on their apparatus are larger at the present time than they have had for months past, and the feeling all along the line seems to be confidently optimistic.

THE LOMBARD GOVERNOR COMPANY, Boston, Mass.—We found busi-

ness conditions during the past year remarkably good. At the beginning of the year we were inclined to think that business might be slack, as the general business conditions at that time were not favorable, but our great difficulty last year was to keep up with our orders. This condition of things has continued steadily, so that we are about to move into a new factory, having about three times the floor space of our present factory. It is always difficult to predict what the condition of business will be for any very great length of time ahead. There is no doubt that general business is in an extremely satisfactory condition at the present time. There are a number of very large projects which will undoubtedly be satisfactorily financed within the next few months. In a general way we anticipate that those who are engaged in building and equipping water-power plants will have a very busy year of it.

AMERICAN ELECTRIC FUSE COMPANY, Chicago, Ill.—During the year 1904 the volume of our business was slightly less than during 1903. The falling off in orders was most noticeable during the months from July 1 to November 1. Since the election the increase in our orders has been very large, indicating that there was a considerable element of suspense entering into the question of business. In the independent telephone field the question of financing the projects made necessary by the public demands for telephones has probably had considerable to do with the comparative shortage in the manufacturing business. In our opinion, the entire question of the future of the manufacturing business in the independent telephone field is purely a question of the ability to secure the necessary capital with which to make necessary developments. The manufacturing outlook for the coming year is encouraging. Advance inquiries indicate that the comparative inactivity of 1904 has resulted in a very large and pressing demand for new material in 1905.

ELECTRICAL EQUIPMENT & SUPPLY COMPANY, Pittsburg, Pa.—In spite of the fact that 1904 was generally considered a panic year, and general business reports have been somewhat unsatisfactory, our experience has been quite to the contrary. Business has steadily increased, and we find it now in a very satisfactory condition, our business in November having shown an increase of 33 1-3 per cent. over the previous month. This is by no means an exception, as in several instances this year we have experienced an increase of 50 per cent. As to future prospects, we feel much encouraged, as everything seems to point to a very satisfactory season. The feature of the indications for the future which seems most satisfactory is the conservative manner in which people are going ahead with work, and not attempting to do everything at once. After every Presidential election, there is a renewed activity which lasts for awhile and then tapers off. In this case, however, the outlook seems to be very stable, as many of the projects which are being undertaken in our territory seem to be of the most conservative and enduring nature.

ABNER DOBLE COMPANY, San Francisco, Cal.—Our business in the water-wheel line during 1904 has been very satisfactory, the volume being greater than we anticipated at the beginning of the year. The business has shown a substantial increase over the previous year, and the outlook for the coming twelve months is very encouraging. Our present works have been overtaxed, and in order to provide facilities for our growing business, we have purchased a three-acre site with railroad connections near the commercial center of San Francisco, where we plan to erect a most modern plant equipped with the latest tools and appliances for the manufacture and testing of everything in the hydraulic line. An interesting feature of the past year's business on the Pacific Coast is the increase in size of hydro-electric units installed in water power plants. During the year the De Sabla power house has been completed, in which are installed two 3700-h.p. and one 8000-h.p. Doble water-wheel units, operating under a head of 1561 feet. The 8000-h.p. water-wheel is the largest single runner unit ever built. We are now constructing three 8000-h.p. water-wheels for the Electra plant of the Standard Electric Company.

NATIONAL ELECTRIC SIGNALING COMPANY, Washington, D. C.—Commercial progress in wireless telegraphy has been almost completely blocked by Government interference during the past year, so far as American companies are concerned. The three openings for wireless telegraphy are to supplant cables, to communicate between ships and shore, and to work over land in the place of wire lines. The first opening has been shut off by the action of the British Government in declining to permit our company to erect stations on British territory. The second opening was blocked by the action of the Joint Wireless Board, recommending that the Government erect stations and handle all messages from ships free of charge, and that no commercial companies be allowed to communicate with ships at sea. The third opening is at the present time a small one, because it is necessary that the multiplex system should be thoroughly developed before wireless telegraphy can enter into competition with the Western Union and Postal Telegraph Companies. So far as the United States is concerned, the year closes with very bright prospects. In some experiments conducted by the United States Navy Wireless Board in August and September of this year this company showed that a station could receive messages without interference while another station only a few hundred yards away was sending at full power. All reason, therefore for Government monopoly has been removed, and it is understood that the United States Government now proposes to make no restrictions on the operation of any bona fide wireless company, other than registration, and does not propose to compete in any way with commercial wireless companies.

OBITUARY.

W. FORMAN COLLINS, for several years connected with the *Western Electrician*, Chicago, died suddenly on December 21. Up to the time of going to press, we have been unable to obtain any particulars.

PERSONAL.

MR. RALPH D. MERSHON, the well-known consulting engineer, has removed his offices from 29 Broadway to 11 Pine Street, New York.

MR. C. C. LEWIS, for the past two years chief engineer of the Schenectady Railway Company, has severed his connection there to join the staff of J. G. White & Co., Ltd., London, England.

PROF. HARRY E. CLIFFORD, Acting Chief of the Department of Electrical Engineering at the Massachusetts Institute of Technology, has been appointed professor of theoretical electricity.

DR. LOUIS DUNCAN, who is well known throughout electrical engineering circles, has been retained by the Allis-Chalmers Co. as an expert in electrical patent work in connection with the Bullock department of the company.

MR. J. H. PERKINS, general superintendent of the Youngstown Consolidated Gas & Electric Company, has resigned that position and accepted the general management of the Wilkesbarre (Pa.) Gas & Electric Company, taking effect January 1.

MR. H. H. SINCLAIR, vice-president of the Edison Electric Company, Los Angeles, Cal., has returned from an eight months' trip to the Sandwich Islands, the Philippines, Japan and other Asiatic countries and resumed his work in Los Angeles.

MR. JOHN McC. PRICE, the well-known and popular salesman of the Electric Equipment & Supply Company, Pittsburg, Pa., has been promoted to the position of general sales manager and now has under his direction the company's entire traveling force.

MR. J. U. JONES, of Dallas, Tex., one of the best-known salesmen in the Southwest, has joined the staff of the Allis-Chalmers Co., of Milwaukee, and will hereafter represent the company in the sale of all of its products in Texas and its tributary territory.

MR. J. B. McCLARY, formerly manager of the Railway Department of the Birmingham (Ala.) Railway, Light & Power Company, has been appointed general manager of the Sheffield Company, his responsibilities including the public utilities of Florence, Sheffield and Tuscumbia.

MR. JOHN CRAIG HAMMOND, Denver, has been appointed chairman of the local publicity committee for the next convention of the National Electric Light Association which is to be held in Denver. The association is to be congratulated in securing Mr. Hammond's services in this capacity.

MR. C. W. WHITNEY, who for some time past has been connected with the McGraw Publishing Company as traveling editor for all of its periodicals, has joined the staff of the Abner Doble Co., San Francisco, builders of the Doble tangential water wheels and designers of electric power and hydraulic plants.

MR. BENJAMIN F. PEARSON, formerly superintendent of power for the Edison Electric Company, Los Angeles, Cal., has been promoted to the position of general superintendent, in which position he will have entire charge of all new electrical construction, as well as the supervision and operation of all of the Edison Co.'s plants.

MR. CHARLES H. TUCKER, recently the assistant chief engineer of Pawling & Harnischfeger, Milwaukee, has been appointed chief engineer of the Case Manufacturing Company, Ohio, designers and builders of cranes and special machinery. Mr. Tucker has an enviable reputation as an engineering expert on crane design and construction.

MR. O. A. STRANAHAN, for the past three or four years in charge of the engine business of the British Westinghouse Company, has been appointed manager of the Power Department of the Allis-Chalmers Co. and will have charge of the

sales of steam engines and turbines and gas engines. Mr. Stranahan's headquarters will be at Milwaukee.

MR. CAMPBELL SCOTT, the well-known secretary and general manager of the C. & C. Electric Company, has resigned that position, taking effect January 1. Mr. Scott has been chiefly responsible for the prominent position in the electrical manufacturing field which his company has attained during his management, and his loss will undoubtedly be much regretted by the other officers of the company. Mr. Scott's plans for the future are not yet sufficiently crystallized to permit any definite announcement of them.

Mr. W. J. SANDO, who has had a wide engineering experience in the field of pumping machinery, has been appointed manager of the Allis-Chalmers pumping machinery department, with headquarters in Milwaukee. Mr. Sando served as chief engineer to the New York City Commission on Additional Water Supply from May 1, 1903, to January 1, 1904, prior to which service he was connected successively with the International Steam Pump Company and E. D. Deavitt, the well-known designer of pumping machinery.

MR. S. M. KEEBLE, who has for many years been associated with the Frank Adam Electric Company, of St. Louis, and under whose management that company's switchboard business has developed into one of the most important of its kind in the West, has resigned his position there to become general sales manager of the Cutter Electrical & Manufacturing Company, with headquarters in Philadelphia. Mr. Keeble's familiarity with the circuit-breaker and instrument business, resulting from his long experience, should make his services of great value in his new position.

TRADE PUBLICATIONS.

MICA. Eugene Munsell & Co., New York and Chicago.—A pocket-size catalogue of India and amber mica, cut and uncut, for electrical work.

ROTARY CONVERTERS. The Bullock Electric Manufacturing Company, Cincinnati, Ohio.—This is Bulletin No. 1031, containing an illustrated description of the Bullock rotary converter.

WINDOW LIGHTING. H. T. Paiste Co., Philadelphia.—A handsomely executed pamphlet containing illustrated descriptions of Fielding specialties for window lighting with incandescent lamps.

INCANDESCENT LAMPS. The Colonial Electric Company, Ravenna, Ohio.—An illustrated catalogue of the Colonial incandescent lamp, which is made in all of the standard candle-powers, voltages and bases.

CALENDAR. The R. M. Cornwell Co., Syracuse, N. Y.—This is a hanging calendar of the familiar pad type, the monthly leaves being fastened to a large paper backing bearing a fancy picture lithographed in colors.

HYDRAULIC TURBINES AND CENTRIFUGAL PUMPS. I. P. Morris Co., Philadelphia.—Bulletin No. 1, containing illustrations and descriptions of some notable turbines and pumping machinery built by this company.

CALENDAR. Pope Manufacturing Company, Hartford, Conn.—A desk calendar for 1905 of the familiar pad memorandum type, containing a separate leaf for each day of the year with a blank space on each leaf for memoranda.

PISTON-ROD PACKING. Holmes Metallic Packing Company, Wilkesbarre, Pa.—A pocket-size catalogue containing a brief description of this packing and illustrations of a number of representative engines on which it is used.

ALTERNATORS. General Electric Company.—Bulletins Nos. 4393 and 4394, containing illustrated descriptions of engine-type and belt-driven revolving-field alternators, each having its exciter incorporated in the main structure.

FOUNDRY APPLIANCES. W. W. Lindsay & Co., Philadelphia.—A well-executed pamphlet of vest pocket size devoted to chaplets and anchors for foundry use. The book is illustrated and contains very complete data and price lists.

STATIC ELECTRICITY NEUTRALIZED. The Portland Company, Portland, Me.—A bulletin containing a description of apparatus devised for neutralizing the static electricity generated by friction on finished paper passing through calendar rolls.

HOUSE TANK PUMPS. The Prindle Pump & Engineering Company, New York.—This is catalogue A, of standard size, containing illustrated descriptions of the Prindle motor-driven centrifugal pumps for use chiefly in connection with house tanks.

COMPENSATED GENERATORS. The Ridgway Dynamo & Engine Company, Ridgway, Pa.—Bulletin No. 14 devoted to the well-known Thompson-Ryan compensated direct-current generator. The bulletin is liberally illustrated and well executed.

GAS AND GASOLINE ENGINES. Marinette Gas Engine Company, Chicago Heights, Ill.—A well-executed catalogue, containing illustrated descriptions of the Walrath gas and gasoline engines which are built in vertical single, double and triple-cylinder styles.

REFLECTORS. Sunlight Reflector Company, Brooklyn, N. Y.—Catalogue No. 6, containing illustrated descriptions and price lists of mirror reflectors of all of the usual shapes for individual lamps, clusters, window fixtures, boiler lights, church ceiling fixtures, etc.

ELECTRIC COOKING AND HEATING APPARATUS. The Prometheus Electric Company, New York.—Leaflets Nos. 1 and 2, containing illustrated price lists of Prometheus food and water heaters, coffee pots, tea kettles, chafing dishes, radiators, sad irons, etc.

THAWING FROZEN WATER PIPES. Pittsburg Transformer Company, Pittsburg, Pa.—An illustrated pamphlet containing a description of this company's special transformer built for pipe-thawing service. The transformer was described in the December number of the AMERICAN ELECTRICIAN.

PUMPING MACHINERY. Henry R. Worthington.—Catalogue W-30 of standard size, devoted to the well-known line of Worthington pumps, both direct-acting, steam-driven and centrifugal pumps driven by different forms of prime movers. The catalogue is profusely illustrated and beautifully executed.

CONDENSING APPARATUS. The Deane Steam Pump Company, Holyoke, Mass.—Catalogue D-23, devoted chiefly to Deane jet and surface condensers, vacuum pumps, air and circulating pumps, etc., and also containing some other useful information on the application of condensers to steam engines in general.

ILLUMINATION. Holophane Glass Company, New York and Chicago.—Two beautifully-executed brochures, one entitled "The Lighting of the Home," and the other, "Lighting vs. Illumination." Both contain a large amount of useful information concerning the distribution of artificial light and the relation of the Holophane glassware thereto.

MECHANICAL STOKERS. The Westinghouse Machine Company, Pittsburg, Pa.—This is a handsome publication of standard catalogue size, opening at the end, devoted to the Roney mechanical stoker. It contains a brief illustrated description of the stoker, some information as to the conditions under which these stokers are in operation, and numerous illustrations of plants already installed.

THE WINTER BOARDER. New York Central & Hudson River Railroad Company.—This is No. 36 of the well-known "Four Track" series of publications, and it contains a list of the principal hotels in New York City and all of the hotels and boarding places in the towns and cities reached by the New York Central system. This company has also issued No. 5 of the "Four Track" series, entitled "America's Winter Resorts," and containing a great deal of useful information concerning such resorts and maps showing the scope of the New York Central's railway system.

CALENDAR. John A. Roebling's Sons Co., New York.—A most convenient vest pocket calendar comprising a "Petite" calendar and stamp case containing a calendar for the entire year bound in flexible leather, and a somewhat larger flexible leather binder adapted to carry a stitched-leaf calendar book for one month. Twelve stitched monthly books accompany the binder and the substitution of each month's book is a matter of a few seconds. Each leaf of the monthly book contains the day of the week and the day of the month with ample space for memoranda.

ELECTRICAL MEASURING INSTRUMENTS. Keystone Electrical Instrument Company, Philadelphia, Pa.—This is catalogue No. 12 of standard size, containing illustrated descriptions of the Keystone line of instruments which include the electro-dynamometer type built in all standard forms and the solenoid type built for switchboard service. The Keystone Company calls attention to the recent court decision in its favor concerning the manufacture of the electro-dynomometer type of instrument. This decision reversed a previous decision of a lower court, which had held the Keystone instruments to infringe Weston patents.

BUSINESS NEWS.

GREEN ENGINEERING COMPANY, Chicago, announces that the Green traveling link-grate stoker was awarded the gold medal at the St. Louis Exposition.

MODEL STOKER COMPANY, heretofore of Akron, Ohio, has removed its factory and headquarters to Dayton, Ohio, where much more advantageous facilities have been secured.

THE NORTH ELECTRIC COMPANY, Cleveland, Ohio, has established a branch office at Dallas, Tex., in charge of Mr. A. A. Miller, who has for some time past been connected with the sales department at the home office.

FELTEN & GUILLEAUME, Mulheim-on-Rhine, Germany, are finding a most gratifying demand for the new cable grip recently put on the market. This device was described in the reading pages of our November, 1904, number.

EMPIRE STATE DRY BATTERY COMPANY has been organized by Mr. John Smith, formerly superintendent of the Electric Contract Company's factory. The new company has well-equipped works at No. 80 Fulton Street, New York.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY, through its Agents, G. & O. Braniff & Co., of Mexico, has been awarded the contract for all of the electrical apparatus to be installed by the El Oro Mining and Railway Company, El Oro, Mexico. This contract amounts to nearly $100,000.

THE BURT MANUFACTURING COMPANY informs us that the statement made in our Personal column last month concerning the former relationship of Mr. Edward James to that company was inaccurate. The Burt Co. states that Mr. James was not in charge of its filter department, but represented that department in Pittsburg and vicinity.

ELECTRICAL EQUIPMENT & SUPPLY COMPANY, Pittsburg, Pa., reports that on accounts of the rapid increase in its business it has been found necessary to take larger quarters. The company is therefore moving from 215½ Fourth Avenue to 336-338 Second Avenue, where it will occupy three floors and the basement.

THE TRUMBULL ELECTRIC MANUFACTURING COMPANY, Plainville, Conn., has increased its line of specialties considerably. The company now builds a most complete line of panel boards, switchboards, switches, fuses and fuse-holders. A catalogue of the full lines will be ready for distribution by the time this paper reaches its readers.

THE A. D. GRANGER COMPANY has moved its Philadelphia office to the Commonwealth Trust Building, Chestnut and Twelfth Streets, where much larger and commodious offices have been fitted up. Mr. T. M. Simpson remains as manager of this office, his territory covering all of that portion of Pennsylvania from Harrisburg to Philadelphia and the southern half of New Jersey.

CONSOLIDATED ENGINE STOP COMPANY, New York, are rather pleased by a reference to the prompt action of their apparatus which was made in a recent court decision relating to a damage suit. The court ruling was based on the judge's acceptance of testimony to the effect that

the automatic engine stop had brought the machinery to a standstill as quickly as it was possible to do so.

ABNER DOBLE CO., San Francisco, has been awarded the Grand Prize for its St. Louis exhibit of a 170-h.p. tangential water wheel. This is the highest award given by the experts at the St. Louis World's Fair. The wheel develops 170 horse-power at 700 r.p.m., with a water pressure of 300 pounds per square inch (equivalent to a hydraulic head of nearly 700 feet). It was direct-connected to a 100-kw. railway generator and was one of the units of the intramural power plant.

PAYNE ENGINEERING COMPANY, New York, reports good business in the engines of its make. Among recent sales were the following: Three 130-h.p. engines for direct connection to dynamos in the Kilmer Building, Binghamton, N. Y.; two 115-h.p. and one 80-h.p. engines for similar service in a New York hotel; two 80-h.p. engines, direct-connected, for Gouverneur Hospital, New York; one 120-h.p. engine, direct-connected, for the New Jersey Zinc Company; one 80-h.p. direct-connected engine for a Brooklyn hotel.

KEYSTONE LUBRICATING COMPANY, Philadelphia, has brought out a new lubricant particularly intended for the electrical field. It is known as No. 6 density grease, and is made for use in all places where lubrication is required, excepting engine cylinders. It is very thin, practically a liquid, and can be applied from an ordinary oil squirt can. The company guarantees this new lubricant to reduce the temperature of any bearing practically to the temperature of the room, and states that one pound of it will go farther than three to four gallons of the best lubricating oil.

BROWN CORLISS ENGINE COMPANY, Corliss, Wis., has secured, in the face of unusually strong competition, a contract to build a large triple-expansion, high-duty pumping engine for the city of Milwaukee. The engine is to be capable of handling twenty million gallons of water an hour, and the contract price was $64,500. There was considerable discussion of the ability of the company to handle such a large piece of work, but a visit to its works by the City Engineer and the Commissioners of Public Works satisfied those gentlemen on that point.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

ATTALLA.—A. L. Du Pre and J. R. Brown, of this city, together with Adolphus Brown, of Ragland, have filed articles of incorporation for the Etowah Light & Power Company. The company is capitalized at $24,000 and its principal place of business will be here. A. L. Du Pre is president, J. R. Brown, vice-president, and Adolphus Brown, secretary and general manager. The company has purchased the water power of W. P. Lay on Wills Creek and will generate electricity for lighting and power purposes in Gadsden, Attalla and Alabama City.

ARKANSAS.

COTTER.—Work is well under way on the ice and electric light plant here.

CLARKSVILLE.—E. T. McConnell, of Eureka Springs, is making arrangements to construct an electric light plant here.

RUSSELLVILLE.—Dr. Robert Smith and several other prominent business men have purchased the electric light plant, which was controlled by Smallwood & Sons.

FORREST CITY.—Reports state that the plant of the Forrest City Electric Light & Power Company has been sold to Capt. George M. Mead, of Little Rock, and some Memphis parties.

POCAHONTAS.—S. C. Dowell, of Walnut Ridge, has been granted a franchise for the Pocahontas Power Company, of which he is president and treasurer. He writes that it is proposed to construct an electric light plant to cost about $25,000.

BATESVILLE.—The Batesville Power Company has been incorporated with a capital stock of $10,000, by F. P. Allbright, William Ramsey and A. R. Weaver. The company will develop water and steam power for the generation of electricity for commercial and manufacturing purposes.

CALIFORNIA.

SAN FRANCISCO.—Jacob Schiff and other New York parties are trying to get a franchise for an opposition electric light and gas plant here.

CALISTOGA.—Bids will be received January 3 by the Town Clerk for a franchise to establish an electric light and power system in this town.

ORANGE.—A resolution has been adopted by the Council providing for the construction of water works and an electric light plant at this place.

NEEDLES.—It is reported that the Murphy Water, Ice & Light Company will construct an independent electric light plant to be used for lighting the city.

COLORADO.

GOLDFIELD.—Rodney Curtis, of the Denver Tramway Company, Denver, is reported to be interested in the construction of an electric plant on Bishop Creek to supply electricity to this town and Tonopah.

COLORADO SPRINGS.—Incorporation papers have been filed by the San Luis Valley Irrigation, Land & Power Company with a capital stock of $1,000,000. A dam will be constructed across the Rio Alamosa River and water will also be taken from other natural streams in San Luis, El Paso, Conejos and Rio Grande counties and used for irrigating lands in those counties. In addition to the irrigation enterprse, the company will establish an electric power plant for generating and distributing electricity to towns and cities in the district mentioned. The directors are S. S. Bernard, William M. Bainbridge, M. F. Stark, W. A. Braiden and W. O. Mieir. The principal offices will be maintained at Colorado Springs.

CONNECTICUT.

HARTFORD.—H. B. Freeman, Jr., of Hartford, and twenty others have prepared a petition to the general assembly of Connecticut applying for a charter for a new electric plant which will furnish power and light in the counties of Hartford and Litchfield. It is planned to install the plant in the mills of the Cotton Duck Trust Company in New Hartford.

NEW MILFORD.—It has been announced that the New Milford Power Company, the largest of its kind in Connecticut, and which furnishes power for trolley systems in Waterbury, New Britain and Bridgeport, and several smaller towns on the line of the Connecticut Railway and Lighting Company, has been reorganized. The new officers are: President, Winthrop G. Bushnell; vice-president, Louis E. Stoddard; secretary and treasurer, Samuel C. Morehouse. The company has an extensive plant in New Milford and an auxiliary plant is being built at Boardman's bridge. Offices will be established in New Haven.

FLORIDA.

GRACEVILLE.—The secretary and superintendent of the Graceville Light & Water Company, writes that the proposed water works and electric light plant will cost about $20,000. Ludwig & Co., of Atlanta, Ga., the engineers in charge of the work.

GEORGIA.

DALTON.—It has been decided by the City Council to construct an electric light and power plant.

GRIFFIN.—The contracts which have been let for putting in a sewerage system and making improvements to the light and water plants of this city are said to aggregate $100,000.

ATLANTA.—The Peachtree Lighting Company has been granted a charter to supply electric lights to the residents of Peachtree Road and other places in the county. The company is capitalized at $600, with the privilege of increasing the capital stock to $5000, and is composed of Arnold Boyles, Martin Amorous and Edwin Brown.

DALLAS.—The Dallas Light & Power Company has been organized by the citizens. A. J. Cooper was made president and E. H. Robertson, secretary and treasurer. The company's capital is $5000 and a charter will be applied for at once. It is proposed to erect an electric light plant first and later a complete water works system will be installed.

IDAHO.

BOISE.—I. B. Perrine is said to be interested in the construction of an electric plant on Trout Creek.

MONTPELIER.—The Montpelier Electric Light Company has increased its capital stock from $25,000 to $40,000.

IDAHO FALLS.—The Idaho Power & Transportation Company is reported to have in contemplation the construction of a dam near this city, and later, the construction of an electric power plant.

ILLINOIS.

ST. CHARLES.—Extensive improvements are being made at the city's electric light plant.

CAYUGA.—The City Council is investigating the cost of establishing an electric light plant.

AMBOY.—The Amboy Lighting & Power Company has changed hands, it is said, Mr. Searles being named as the purchaser.

ROCK ISLAND.—The Council has approved a contract with the People's Power Company to furnish light and power for the reservoir plant and the water works plant.

BELLEVILLE.—The Ada Electric & Gas Company has filed articles of incorporation, with a capital of $100,000. J. A. Hamilton, A. R. Daab and L. D. Turner, Jr., are the incorporators.

MACKINAW.—A franchise has been granted by the Board of Trustees to a stock company organized for the purpose of rebuilding the electric plant which was recently destroyed by fire. The incorporators are S. A. Thompson, George Tyrrell and C. G. Sparks, and the capital stock is placed at $10,000.

MORRISON.—George A. Whitcomb, one of the incorporators of the Rock River Hydro-Electric Milling and Power Company, writes that it is proposed to build a dam across Rock River at Lyndon, Ill., and construct a power plant of from 1600 to 2500 horse-power. Work will be commenced early in 1905.

MOLINE.—The People's Power Company, of this city, has increased its capital stock from $600,000 to $1,000,000. Among the improvements contemplated are an addition to the old plant, the purchase of a 2500-h.p. generating unit, connections to be made to additional water wheels and a building for purifying gas.

INDIANA.

LEBANON.—Edmund Connor, City Clerk, writes that a franchise has been granted to the Citizens' Electric Light & Ice Company.

DUNKIRK.—The Dunkirk Lighting Company has been incorporated by Charles A. Harkins, Charles O. Reynolds and Jesse M. Soper, with a capital of $21,000.

KOKOMO.—George Kingston, John W. Johnson and Edward S. Huff have filed articles of incorporation for the Kokomo Electric Company, with a capital of $10,000.

CHRISNEY.—The Chrisney Electric Light Company has been incorporated, with a capital of $1500.

The directors are J. C. Fella, B. N. Fish, J. M. Fella and John B. Chrisney.

TERRE HAUTE.—The Board of Public Works has recommended to the City Council the bid of the Terre Haute Traction Company for lighting the streets for a period of five years at $75 per lamp per year on an all-night schedule.

MATTHEWS.—Articles for the incorporation of the Matthews Electric Light & Power Company, with a capital stock of $15,000, have been filed at the Auditor's office. The directors are Philip Hughes, Guy S. Rinebolt, E. W. North, Everett W. Trook, and others.

EVANSVILLE.—The Evansville Gas & Electric Light Company has secured the contract for lighting the city for five years at the following bid: Electric arc lights of 2000 candle-power at $67 per lamp per year; incandescent gas lights at $20 per lamp per year, and gas at $1 per thousand cubic feet for lighting public buildings.

INDIAN TERRITORY.

RAMONA.—The Ramona Light, Heat & Power Company has filed articles of incorporation.

IOWA.

CRESTON.—E. M. Springer and Mr. Harrison, of Red Oak, are making arrangements to establish a new electric light and heating plant in Creston.

CLARKSVILLE.—The plant of the Clarksville Light, Heat & Power Company is said to have changed hands recently, the purchaser being Willis Sutcliff.

CLARINDA.—The Lee Electric Light Company has been incorporated, with a capital of $50,000. Mr. R. B. Lee is among the incorporators.

DAVENPORT.—The People's Power Company has increased its capital stock from $60,000 to $1,000,000 and will make extensive improvements to its property during the coming year.

LEON.—The municipal electric light plant has been sold to W. S. Curtis and H. E. Chase. The new owners will improve and enlarge the plant and endeavor to render an efficient and up-to-date service.

FAIRFIELD.—The Fairfield city council has entered into a contract with the Western Electric Company, of Chicago, for a new lighting plant to be installed in this city as soon after the first of the year as possible. There will be seventy-five lamps, each 2000 candle-power. The dynamo of the present lighting plant will carry fifty lamps, so that there will be at least one hundred and twenty-five lamps. The price of the new plant will be $2,735.

KANSAS.

ELDORADO.—W. Martin Jones has been granted a franchise to establish an electric light plant here.

MANHATTAN.—C. P. Dewey, of Chicago, has been re-elected president of the Manhattan Ice, Light & Power Company.

KENTUCKY.

STURGIS—Mark E. Easton, Mayor, writes that a twenty-year franchise has been granted to the Sturgis Electric Light Company, of this town.

FULTON.—It is rumored in business circles that local capitalists are interested in the construction of a new electric light plant in Fulton, but nothing definite is known as yet.

LOUISIANA.

LAKE PROVIDENCE.—The City Council has let the contract for constructing the municipal light and water plant to A. B. Sanders, of Shreveport, for $37,000. Arthur Hider, of Greenville, Miss., is the engineer in charge of the work.

MAINE.

FORT FAIRFIELD.—The Fort Fairfield Electric Company has been organized by Harry L. Cram and A. J. Desmond, both of Portland, for the purpose of furnishing gas and electricity in Fort Fairfield. The company's capital is $40,000.

MARYLAND.

LUTHERVILLE.—It is reported that the Baltimore County Commissioners expect to install an electric lighting system in the village shortly.

BALTIMORE.—Mayor Timanus has signed the franchise authorizing Richard B. Fentress and Summerfield B. Medairy to use the city subway for the transmission of electricity for lighting and power purposes and also to erect poles and string wires outside the subway district. Arrangements have been made with the Baltimore Refrigerating & Heating Company for the generation of electricity at its large plant on South Eutaw Street. This power will be distributed by Messrs. Fentress and Medairy, who have already secured a number of large contracts in the new district, it is said. The Refrigerating & Heating Company is at present installing an additional battery of boilers of 1000 horse-power capacity and the necessary electrical machinery will also be put in at once; it is proposed to expend about $1,000,000 in new apparatus. Messrs. Fentress and Medairy have begun stringing the wires.

MICHIGAN.

BERRIEN SPRINGS.—J. Du Shane, of South Bend, Ind., writes that it is proposed to construct a power dam at this place, but that nothing will be done this season. The cost of the work is estimated at about $1,000,000.

DETROIT.—At a recent meeting of the Council, John Russell petitioned the Springwells Township Board for an electric lighting franchise for that portion of Springwells Township not included in the villages of Woodmere and Delray.

JACKSON.—A big power dam project is under way to furnish power for electric lighting for Whitehall and Montague and other purposes. R. H. Updyke, a civil engineer from Grand Rapids, has been working for the last two years on a plan and has the details nearly completed for the damming of White River and the construction of a large power house on the dam. A forty-foot head of water will be maintained and in the power house will be large dynamos which will generate enough power to transmit current for electric lighting, pumping and for electric cars as far as Grand Rapids.

MINNESOTA.

GREY EAGLE.—Guy Robbins has secured a franchise for an electric light plant here.

MIDWAY.—The Electric Light & Power Company, it is said, expects to erect a new plant here.

JORDAN.—The Jordan Electric Light & Heating Company will shortly increase its equipment by the addition of a storage battery system.

ANOKA.—The Anoka Water Works, Electric Light & Power Company expects to add to its equipment a new dynamo of 2000 lights capacity.

AITKIN.—The Aitken Power & Light Company has filed articles of incorporation, with a capital of $10,000. Clark S. Kathan and Nelson I. Cluff are among the incorporators.

WINTHROP.—The Electrical Machinery Company, of Minneapolis, secured the contract for making the extensions and improvements at the electric light plant and water works for $7530.

MANKATO.—Plans and specifications are being prepared for a complete railway, light, heat and power plant to be installed shortly by the Mankato Railway, Light & Power Company.

BAGLEY.—Bids will be received January 3 by the Village Council for bonds to the amount of $13,000, the proceeds to be used in purchasing an electric light plant and constructing a water works system.

MINNEAPOLIS.—An ordinance has been introduced in the Council, providing for a 30-year franchise to the Minnesota Power & Trolley Company, of Champlin, to erect poles and string wires for the transmission of electricity to this city.

MINNEAPOLIS.—The Rainy River Improvement Association, with a capital of $5,000,000, has been incorporated to build a concrete dam across Rainy River to raise the lake and thus furnish more power. The incorporators are E. W. Backus and A. E. Horr, of this city, and H. B. Winchell, of Butte, Mont.

MINNEAPOLIS.—The Council Committee on Lighting has recommended that contracts for lighting the city for the year beginning January 1 be awarded as follows, all being on the all-night schedule: The Minneapolis General Electric Company for street arc lights at $94 per lamp per year; the Minneapolis Gas Light Company for gas at 95 cents per thousand cubic feet, and the Patterson Street Lighting Company, of Cleveland, for incandescent fixtures and maintenance at $13.40 per lamp per year.

MISSISSIPPI.

GRENADA.—The Council is making arrangements to enlarge the electric light plant.

HATTIESBURG.—The City Council has granted to G. L. Hawkins and associates the right to erect, maintain and operate an electric lighting plant in Hattiesburg. The franchise includes the right to lay single or double tracks and everything pertaining to a first-class street railway system, and is for twenty-five years. The company shall by June 1, 1905, commence work in good faith, and complete, equip and have in operation at least three miles of its line not later than January 1, 1906. It is rumored that Captain J. T. Jones, president of the Gulf & Ship Island Railroad, is an interested party with Mr. Hawkins.

MISSOURI.

HANNIBAL.—Work is progressing rapidly on the new city electric light and power plant here.

GLASGOW.—A franchise has been granted for the construction of an electric light plant here, and it is understood that work on the new system will soon begin.

CHILLICOTHE.—At an election held recently, the citizens voted to have the electric lights turned off rather than pay an advance of $7 per light on the present cost.

BOWLING GREEN.—Thomas Melvin, formerly of New York City, has leased the electric light plant here from N. H. Ledford, and intends to make extensive improvements in the near future.

JEFFERSON CITY.—The citizens have voted to extend the franchise of the electric light and gas company for twenty years and the company, it is said, has agreed to expend $75,000 in improving the plant.

ST. LOUIS.—The Security Electric Heating & Power Company, with a capital stock of $300,000, has filed articles of incorporation. Among those interested in the undertaking are Samuel D. Winter and Dudley S. Wageley.

EL PASO.—The El Paso Gas & Electric Company has filed articles of incorporation, with a capital of $500,000. Among the incorporators are William Barrett Ridgely, Washington, D. C.; George Goodnow, Waukegan, Ill., and Charles Barrett, of this city.

ST. LOUIS.—Reports state that the Union Electric Light & Power Company's plant was damaged by fire recently to the extent of about $5500. The company has secured a building permit for the erection of a sub-station at 709 North Fourth Street. The new station is to cost $26,000.

HALE.—Preparations for the erection of an electric light plant at this point are being made. The company which has the project in hand will be known as the Citizens' Electric Light & Land Company. A. J. Herren is president; W. L. Ballow, secretary and treasurer, and Fred Halbauer, general manager.

JOPLIN.—Press reports state that the Spring River Power Company, of Kansas, has filed articles of incorporation in this state to show that it had been incorporated under the laws of the State of Missouri, with a capital of $450,000, of which $50,000 is to be employed in Missouri. The company is also to have an office in this city.

MONTANA.

LIVINGSTON.—C. S. Hefferlin has applied for a thirty-year franchise for an electric light and power plant.

WHITEFISH.—The Big Fork Electric Power & Light Company is said to have secured a franchise for its pole line from Kalispell to this city.

WHITEFISH.—George Nixon, of Spokane, Wash., is making surveys for an electric light plant and water works, the power to be developed from Hell Roaring Creek.

NEBRASKA.

CRAB ORCHARD.—A municipal electric light and power plant is to be installed here.

OMAHA.—The Baxter Springs Electric Company has been incorporated with a capital of $30,000.

EDGAR.—The City Council has granted a franchise to Keefe & Larkin for lighting the city by electricity. They will erect a plant at once.

NEVADA.

GOLDFIELD.—A project is under way to supply this camp and Tonopah with electric lights and power from Bishop Creek, Inyo County, California, and the probabilities are that the work on the great undertaking will begin within a few weeks. Denver and Goldfield parties are behind the scheme, which involves the expenditure of nearly a half million dollars and the running of feed wires from Bishop to Goldfield and Tonopah, a distance of eighty miles, directly across the White Mountains. Already water rights have been secured on Bishop Creek and surveys for the plant and the wire lines have been made.

NEW JERSEY.

PERTH AMBOY.—The Public Service Corporation has secured the contract for lighting the city for five years at $97.50 per lamp per year.

BRIDGETON.—City Recorder Frank L. Hewitt writes that the Council has awarded the contract for lighting the city for a period of five years to the Bridgeton Electric Company.

JERSEY CITY.—The North Jersey Electric Light, Heat & Power Company has filed articles of incorporation, stating its capital stock to be $100,000. F. J. Smith and B. P. Tracy are among those interested in the new concern.

NEWTON.—The Newton Gas & Electric Company has replaced its old street arc lamps with others of an improved pattern. When the new plant, now in course of construction, is completed the company will institute a 24-hour service instead of the present night service.

TRENTON.—The City Council at a recent meeting adopted a resolution providing for the appointment of a committee with power to investigate the advisability of constructing an electric light plant. Messrs. Throp, Fischer and Stilwell were appointed members of the committee.

IRVINGTON.—The United Electric Company has been awarded the contract for lighting the city for a period of five years at $15 per lamp per year for a 30-c.p. light. This disposes of the question of municipal ownership of a lighting plant, which has been under discussion here recently.

JERSEY CITY.—The Michigan Light Company, with an authorized capital of $2,250,000, has been incorporated by Walter B. Mahoney, Walter Thiele and Charles N. King, all of this city. The company's office will be in Jersey City, and it is proposed to construct and operate heating and lighting plants.

EAST NEWARK.—After much discussion, the Common Council has accepted a contract submitted by the Public Service Corporation to supply light to the borough at the rate of $100 per lamp per year, which is a reduction of $7 per lamp from the former price. The contract is to run five years, from July 1, 1904.

NEWARK.—The Middlesex Lighting Company of Newark has been incorporated to generate and distribute electric current for light, heating and power purposes. The company is capitalized at $100,000, and among the incorporators are Albert B. Carlton, Elizabeth; Percy S. Young, Passaic, and Frederick Evans, New York City.

PASSAIC.—The City Council has awarded the contract for lighting the city streets for five years and furnishing the incandescent lamps to the Weehawken Construction Company at the following bid: Arc lights $88 each per year; incandescent street lights, $15 per year; incandescent lighting for public buildings, 10 cents per kilowatt-hour; incandescent lighting to private individuals, not more than 10 cents per kilowatt-hour. The company further agrees to erect and have in operation within eight months from the date the contract is signed a complete plant, fitted with the most up-to-date equipment.

KEARNY.—Two electrical experts have submitted estimates to the lighting committee of the cost of a municipal electric light plant. One of the estimates placed the cost at $50,000, while the other showed figures of $55,000. As the Council desires sufficient time in which to erect a plant, and the present contract with the Public Service Corporation expires August 1, 1905, a resolution was adopted requesting Clerk Wildman to secure bids for lighting the town. At the opening of the bids that of the Public Service Corporation was found to be the only one submitted, and it was decided to return it and call for other bids.

NEW YORK.

BROOKLYN.—The Astoria Light, Heat & Power Company is arranging to put up a new building to cost $140,000.

LIVONIA.—F. A. Wicker, B. C. Black and Elbert Long are said to be interested in the construction of an electric light plant here.

HUNTINGTON.—The Huntington Light & Power Company has absorbed the Huntington Gas Company, of which Edgar L. Street is president.

CANANDAIGUA.—There is some talk here of constructing a municipal electric light plant. The subject will probably be voted upon at the annual election in February.

BUFFALO.—The Phelps Lighting Company, with a capital stock of $50,000, has filed articles of incorporation. William Hooker, of Batavia, and E. W. Phelps are on the board of directors.

MASSENA.—The St. Lawrence Transmission Company has been incorporated to generate and distribute electricity for light, heat and power purposes. The company's capital is $25,000.

HARRISVILLE.—The Harrisville Electric Light & Power Company has been incorporated with a capital of $10,000. The directors are Thomas J. Wilbur, Joseph Weeks, Sr., and J. E. Harney.

LOCKPORT.—Engineers are at work laying out the final survey for the power canal to be constructed by the Niagara, Lockport & Ontario Power Company. Robert E. Drake and Paul T. Brady, of Syracuse, are directors of the company.

ALBANY.—The Northern Westchester Light & Power Company has filed articles of incorporation, with a capital of $5000. R. S. Hull, of Brooklyn; A. S. Andrews, of Flushing, and John Larkin, of New York, are the organizers of the enterprise.

NEW YORK CITY.—The Board of Estimate has passed a resolution authorizing Corporation Counsel Delaney to prepare an amendment to the charter to be presented at the coming session of the Legislature providing for the establishment of a municipal electric lighting plant.

NORTH TONAWANDA.—The Home Electric Light & Power Company has petitioned the Board of Aldermen for a franchise to string and maintain the necessary cables and wires for the distribution of electricity for lighting and power purposes. The company will use the poles of the Niagara County Home Telephone Company.

VALLEY STREAM.—A company, known as the Queens-Nassau Electric Light & Power Company, has been incorporated. The company will do business in Nassau, Queens, Kings, Suffolk, Richmond and Westchester counties. The capital stock is placed at $100,000, and the directors are G. F. Swinnerton, A. Foshay and R. K. Tompson.

NEW YORK CITY.—The Commonwealth Electric Company has made application for a charter in Pennsylvania, and efforts are being made to secure a complete light and power franchise for this company in Philadelphia in competition with the Philadelphia Company. It is reported that George R. Sheldon is connected with the Commonwealth Company.

MIDDLETOWN.—Philip N. Jackson, who recently bought the property of the Orange County Gas & Electric Company, proposes to reorganize the company under the name of the Orange Lighting Company, with an authorized capital stock of $100,000 and $300,000 bonds, of which $114,000 will be used to wipe out existing indebtedness and $86,000 be applied toward improving the plant.

MASSENA.—Norman K. Devendorf, chief operator of the Hudson River Water Power Company and formerly superintendent of this company's power house at Mechanicsville, has resigned his position with the Hudson River Company to accept a responsible post with the St. Lawrence River Power Company, Massena, N. Y. He will have charge of the company's transmission lines.

NORTH CAROLINA.

TARBORO.—The power house of the city electric lighting plant has been destroyed by fire, entailing a loss of $3000.

MURPHY.—The Murphy Electric Light & Power Company has been chartered by J. Gentry. The capital is placed at $6000.

OHIO.

CANTON.—A franchise has been granted to the Citizens' Light, Heat & Power Company to operate in this city.

IRONTON.—The Board of Public Service is reported to be considering the advisability of installing an electric plant at the city water works.

YOUNGSTOWN.—A committee has been appointed, with R. D. Campbell as chairman, to investigate the matter of installing an electric light plant.

TOLEDO.—F. I. Consaul, City Engineer, is authority for the report that the city is agitating the matter of installing a municipal lighting plant within the next two years. The present contract with the Toledo Railway & Light Company expires January 1, and it is probable that a short-term contract will be made with the same company.

OKLAHOMA TERRITORY.

OKLAHOMA CITY.—Articles of incorporation have been filed by the Banner Electric & Manufacturing Company, with a capital of $10,000. Charles Luck, Charles Risden and Warren Snyder are the promoters of the concern.

ANADARKO.—It has been decided to build a municipal lighting plant and an engineer is now preparing estimates and plans. It is the intention of the Council to operate the lighting system in connection with the water works system, using practically the same power for both.

OREGON.

UNION.—T. H. and C. H. Crawford are interested parties in the installation of a 2500-h.p. plant at this point.

BAKER CITY.—The Baker City Gas & Electric Company has secured the contract to furnish power for the Elkhorn mine. A sub-station will be established near the mine for receiving and distributing the current to the various parts of the mine.

GREENHORN CITY.—C. R. Aldrin, promoter of a plan to establish an electric power plant here, announces that all arrangements have been completed and that work on the plant will be started in the spring. It will be a water power plant with a capacity of 8800 horse-power.

HAINES.—The Town Council has granted to J. F. O'Bryant, of Baker City, a franchise to establish an electric light and power system. The necessary machinery has been ordered and the work is to commence within sixty days. A line will be run from the nearest point on the Rock Creek Power & Transmission Company's line to a sub-station which is to be erected. From here the current will be distributed by means of transformers.

LA GRANDE.—The La Grande Electric Company has consolidated with the Cove Power Company, the former company being in need of more power. The new company has been incorporated under the name of the Grande Ronde Electric Company. Walter Pierce, J. A. Thornton and T. R. Berry are named as the directors. The water from Cove will have a fall of 890 feet and will require 3700 feet of pipe to convey it to the power station, where 800 horse-power will be developed. A transmission line, connecting Cove, Union, Hot Lake, La Grande, and other towns in Union County, will be constructed with as little delay as possible, and it is expected to reach this city by June 1 next.

PENNSYLVANIA.

UPLAND.—Louis R. Page is interested in the establishment of a lighting plant at this place.

NEW MILFORD.—The New Milford Light & Power Company, with a capital of $10,000, has been incorporated.

GROVE CITY.—At a special election held recently it was voted to issue $12,000 bonds for the purpose of enlarging the power house and extending the present system.

HOMESTEAD.—A deal has been closed recently for the purchase of the old Homestead electric plant from T. W. Brockman by the Lawson Manufacturing Company for $13,500.

PHILADELPHIA.—The Commonwealth Electric Company has petitioned the City Council for a franchise to run electric wires for light, heat and power in the conduits owned by the Keystone Telephone Company.

RENOVO.—The Council has decided to call for bids for lighting the streets with arc and incandescent lights. Bids will also be received for the construction of a municipal electric light plant, in order that a more accurate comparison may be made of the relative cost of lighting the town by contract and operating a city plant.

CHAMBERSBURG.—The Borough Council has accepted the bid of Charles Walter, representing the Chambersburg Light, Heat & Power Company, at $75,550 for the electric light plant which the borough has owned and operated for fifteen years. The company entered into a contract to light the streets of the town at $74.50 a year for each arc light.

FOREST CITY.—The Forest City Electric Light, Heat & Power Company, of which A. D. Kelwen is superintendent, contemplates making extensive improvements to its plant, which will enable it to furnish light to the borough of Vandling and also to render improved service here. Estimates on additional equipment, engine and boilers are being considered now.

WILKESBARRE.—Chicago capitalists have purchased the Nanticoke Electric Light & Gas Company, the Plymouth Electric Light & Gas Company, the Kingston Gas Company and the Wyoming Electric Light Company. These companies supply light to eleven towns between Pittston and Nanticoke. Last year they earned in the aggregate $60,000. It is understood the price paid for the property was $602,000. All the plants will now be consolidated and run by one company, with a capital of $1,000,000.

PHILADELPHIA.—It is understood that the only bid received and opened on December 12 for lighting the city by electricity for the year 1905 was submitted by the Philadelphia Electric Company. The bid to light the entire city aggregates $1,137,500. The prices range from 28 cents to 34 cents per light per night. There will be next year 10,312 electric arc lights. The Philadelphia Electric Company has awarded to John R. Wiggins & Co. the contract for the $50,000 building which is to be erected for the company on Penn Avenue.

SOUTH CAROLINA.

GEORGETOWN. — The Georgetown Electric Company has been reorganized, it is said, with H. C. Case, Philadelphia, president, and L. Mouzon, of this city, local manager. Extensive improvements are contemplated.

MARION.—A charter has been issued to the Carolina Water, Light & Power Company, which proposes to operate power plants in this state and elsewhere. The company's capital is $250,000 and the incorporators are J. W. Johnson and W. J. Montgomery.

NEWBERRY.—The Parr Shoals Power Company, of Newberry, has been chartered, the capital stock being placed at $50,000, with the privilege of increasing it to $1,000,000, and the corporators being H. L. Parr, Z. F. Wright, W. G. Houseal, C. H. Cannon, W. K. Sligh and A. L. Scott. The company proposes to develop the great water power on Broad River, near Peak's, between Newberry and Columbia, furnishing electric current to various cities and towns in the State. It is expected that more than 25,000 horse-power will be developed. The Shoals were formerly the property of Mr. H. L. Parr, of this place, but have now been purchased by a joint stock company, which has interested a number of large capitalists. The surveys and measurements have already been made, and it is believed that the power is one of the finest on Broad River.

TENNESSEE.

LAFOLLETTE.—The question of constructing water works and an electric light plant, at a cost of $100,000, is being discussed here.

CLIFTON.—F. A. Mansfield, proprietor of the ice factory, has decided to construct an electric light plant to furnish lights for the town.

MARTIN.—It has been decided by the City Council to install a new engine and dynamo at the water and light plant in order to run a day circuit.

MEMPHIS.—The Committee on Gas and Electricity of the Legislative Council is considering the question of municipal ownership of an electric light plant.

PETROS.—The Big Brushy Coal & Coke Company has completed its new electric light plant which is to supply lights to the town, as well as current for electric haulage and lighting purposes at the mines.

OBION.—J. E. Trout, L. A. Ward, I. Rosenthal, D. A. Dean, George A. Moore, J. W. Buchanan, and James F. Darnell have organized a company, with a capital of $6000, to construct and operate an electric light plant.

TEXAS.

GREENVILLE.—It has been decided not to sell the electric light plant, but bonds for $10,000 will be issued to enlarge and improve it.

DALLAS.—The Oak Cliff Water Supply, Electric Light & Power Company has sold its electric light plant to the Dallas Electric Light & Power Company.

HUMBLE.—A charter has been granted to the Humble Electric Company with a capital of $30,000. It is proposed to install and operate an electric light plant.

JACKSONVILLE.—J. K. Nance, of Ada, I. T., has purchased the plant of the Jacksonville Electric Company and is planning a number of improvements.

MARBLE FALLS.—A 2000-h.p. plant is to be established on the Colorado River at this point, the power to be used to drive machinery for a cotton mill and for lighting purposes.

EL PASO.—The El Paso Gas & Electric Company has been incorporated with a capital of $500,000. It is proposed to supply gas and electric light, heat and power to this city, Juarez, Mex., and other towns. Among those interested in the project are George F. Goodnow, Waukegan, Ill.; Fletcher S. Heath, Chicago, Ill., and Charles Bassett, of this city.

VERMONT.

RUTLAND.—A bill has been introduced in the Legislature granting permission to this city to establish a municipal electric light plant. J. S. Carder is Mayor.

NORTHFIELD.—Village Clerk J. H. Talbot writes that the electric light plant, recently burned, will probably be rebuilt within a year. A contract will be made with Moody & Almon to furnish electricity for one year.

BURLINGTON.—The Northern Electric Company has secured the contract for the interior wiring and fixtures for the buildings, and the erection of poles and the establishment of an arc light system for the exterior lighting of Fort Ethan Allen. The contract for furnishing the current has been awarded to the Burlington Light & Power Company. It will furnish current for interior lighting at 5 cents per kilowatt-hour and for exterior lighting at $78 for each arc lamp. This company will furnish the arc lamps, meters and transformers.

VIRGINIA.

COLONIAL BEACH.—The Colonial Beach Electric & Power Company has been incorporated for the purpose of conducting an electric light and power business. The company is capitalized at $25,000 and its officers are as follows: Warren S. P. Combs, president; F. F. Ninde, vice-president; W. Frank Renshaw, secretary and treasurer.

WASHINGTON.

BALLARD.—Louis V. Brewer has petitioned for a franchise for an electric light plant.

SEATTLE.—The citizens voted December 6 to issue $250,000 bonds for the extension of the present municipal electric light plant. R. H. Thompson is city engineer.

GOLDENDALE.—A. Robinson, of Portland, Ore., secured a franchise to establish and maintain an electric light plant in this town. The plant will be operated by steam power.

PROSSER.—E. F. Benson is said to have secured a controlling interest in the Land & Irrigation Company and expects to put in an electric light plant. An electric road may be built to Sunnyside.

EDMONDS.—The Edmonds Electric Light & Transportation Company recently filed article of incorporation fixing the capital stock at $1,000,000. John A. Hoffman, M. S. Hutton and Frank B. Sayee are among the parties interested in the new concern.

SEATTLE.—The Puget Sound Light & Heat Company, capitalized at $1,500,000, has been incorporated by Alexander Hamilton, Herbert V. Perry and Antony Zurich. There has been considerable discussion over the franchise of this company, together with those of the Mutual Light & Heat Company and the Diamond Ice Company, but it is understood that the Council and all three of the companies have agreed upon amended franchises.

WEST VIRGINIA.

BRUNSWICK.—The Harper's Ferry Electric Light & Power Company is reported to be making preparations to supply this town with electric light. John Leslie, of Hinton, is president of the Harper's Ferry Company.

WISCONSIN.

CASSVILLE.—The Village Council is seriously discussing the question of constructing a village lighting plant.

LA CROSSE.—The Wisconsin Light & Power Company is a concern recently organized with a capital of $200,000. H. A. Salzer and J. J. Hogan are among the incorporators.

ALMA.—The Alma Electric Light Company has been incorporated with a capital of $5000. John Harry, Russell N. Smith, Frank Harry and Charles Schaettle are the incorporators.

CADOTT.—The Cadott Lighting & Power Company has been organized and incorporated by John McGilvray, H. B. Frasil and others. The company has purchased the lighting plant of the Cadott Manufacturing Company. A new alternating-current system will be installed and the plant will be greatly improved. A new power house is to be constructed on the Yellow River.

CANADA.

PALMERSTON, ONT.—It has been decided to issue bonds to the amount of $2500 for electric light improvements.

CALGARY, N. W. T.—The City Council has decided to submit to the people a by-law to raise $60,000 to be used for the purpose of installing a municipal lighting plant.

ST. JOHNS, QUE.—Edouard Beaudry, a Montreal real estate dealer, has purchased the property and plant of the St. Johns Electric Light Company, it is said, in consideration of $300,000.

MONTREAL, QUE.—The water power at Kakapecca Falls is to be developed by Montreal capitalists. The purchasers are Herbert S. Holt, president of the Montreal Light, Heat & Power Company; Charles R. Hosmer, president, and F. W. Thompson, vice-president and general manager, of the Ogilvie Flour Mills Company, Ltd. It is understood that arrangements have been made for the immediate construction of a plant that will have an initial capacity of 30,000 horse-power which will be increased ultimately to 50,000 horse-power.

American Electrician.

Vol. XVII. New York, February, 1905. No. 2.

TYPICAL FRENCH HYDRO-ELECTRIC AND TRANSMISSION PLANT

THE GENERATING STATION AT CHAMP.

BY EMILE GUARINI.

The hydro-electric station near Grenoble embodies several unusual and interesting features in its hydraulic and electrical equipment. The plant is situated near the junction of the Drac and Romanche rivers, and the power is used exclusively for transmission. The flow of the Drac River varies within very wide limits, and the current is very swift. At Champ the bed of the river is very shallow, so that the width during high water often exceeds one kilometer. It is, therefore, impossible to confine it by a large dam without still further increasing its width. The water is taken from the Drac at Champ by means of a low dam in the bed of the river. This dam is constantly under the river level, but is sufficient to create a current of water from a side outlet having a width of 16 meters (52 ft.), bordering a long intake provided with gratings in the form of light shutters which prevent the ingress of rubbish and stones which are naturally abundant in so violent a stream. The current passing along the side of the intake favors the discharge of gravel and stones through the outlet. What passes the shutters enters the receiving basin. After passing this basin, the water flows into a large settling chamber from which runs a canal 600 meters (1968 ft.) long, terminating in the basin where the pipe line starts. The canal, which starts at the settling basin, has a width varying from 60 to 22 meters (197 ft. to 72 ft.), and a depth from 1.50 to 4 meters (5 ft. to 13 ft.). The water basin which serves as a terminus for the canal and from which the pipe starts is built of concrete. It has a total surface of 900 square meters (9688 sq. ft.). This basin is divided by means of a wall into two compartments. The concrete tube starts from the second compartment and forms the first section of the penstock. The pipe is 3.3 me-

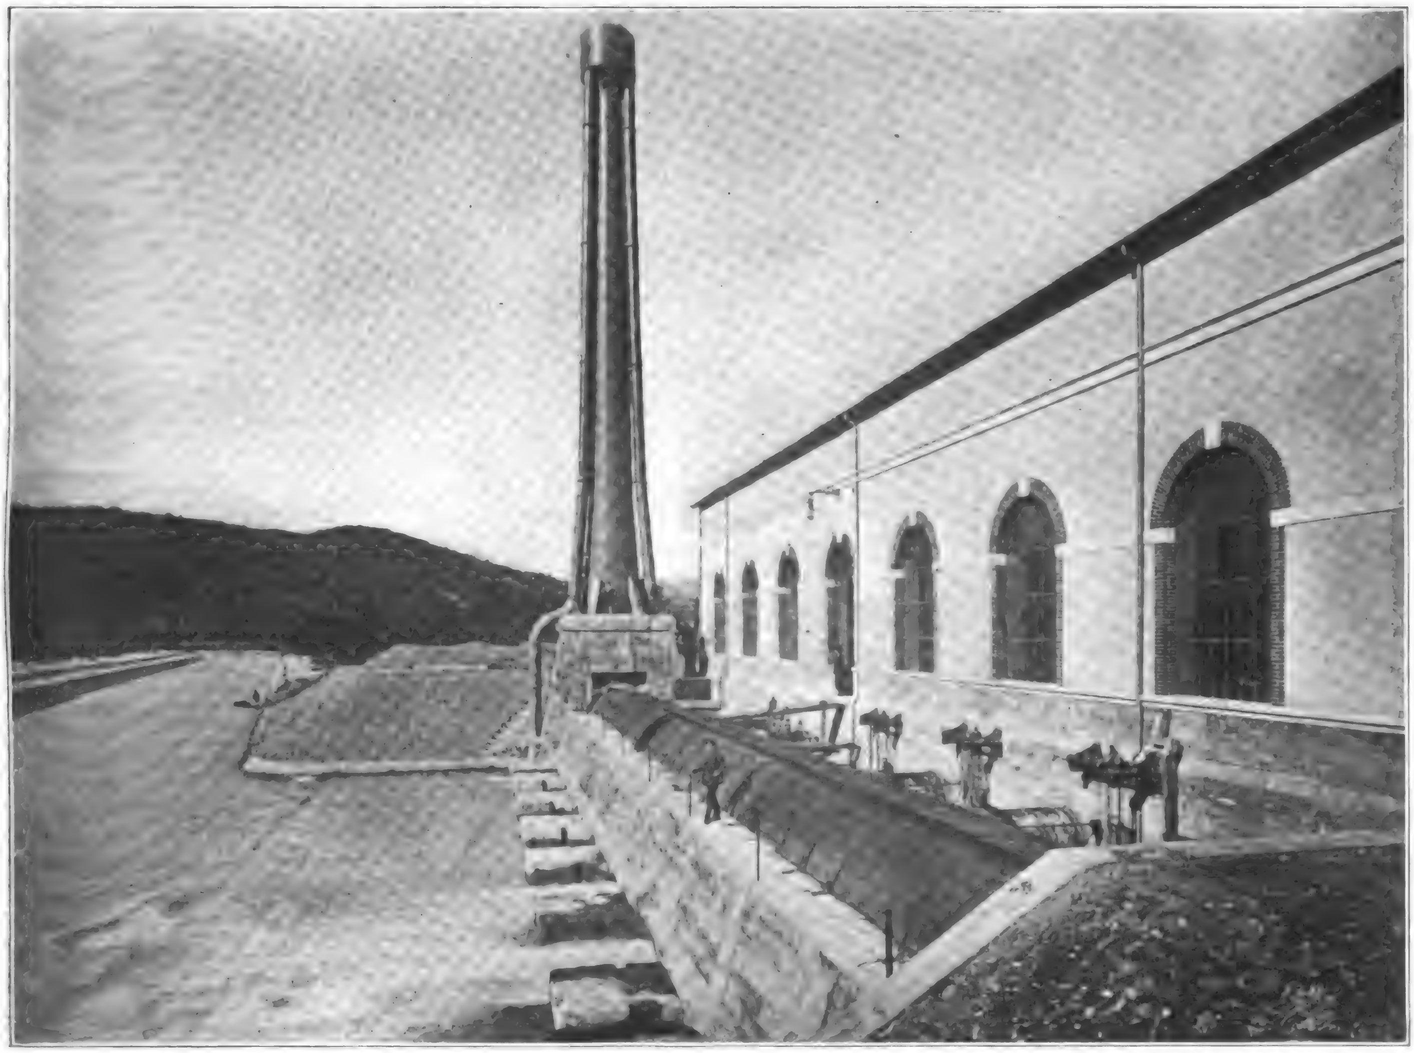

FIG. 1.—POWER-HOUSE, CANAL AND FOREBAY OF THE ELECTRIC GENERATING STATION AT CHAMP.

ters (11 ft.) in diameter, and is 4600 meters (15,090 ft.) long. Of this, 2100 meters (6890 ft.) is formed of re-enforced concrete and 2500 meters (8200 ft.) of sheet steel. The volume of water in the whole length of the penstock is 40,000 cubic meters, flowing with a velocity of 2 meters per second, so that it has been necessary to guard against water hammer in case of an abrupt stoppage at the station. To this end, three standpipes have been placed on the pipe line, two of re-enforced concrete and one of steel.

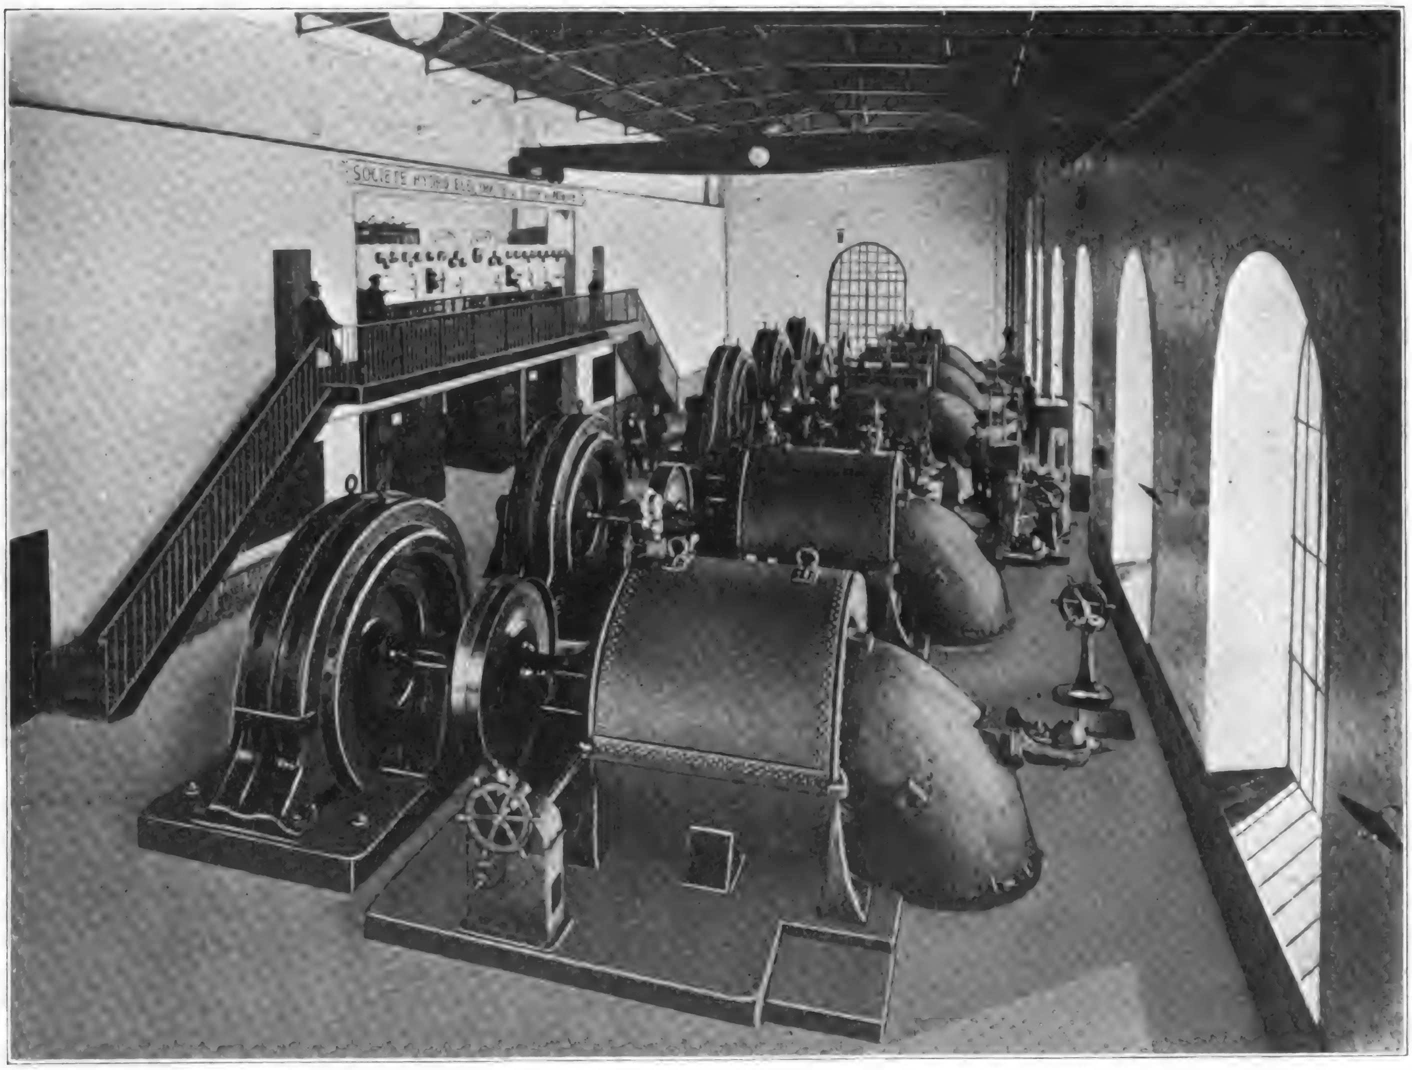

FIG. 2.—INTERIOR OF CHAMP STATION, SHOWING HYDRO-ELECTRIC UNITS AND SWITCHBOARD.

The station contains five generating sets, each rated at 1350 horse-power, and two exciter sets of 150 horse-power each. In addition to these, a small 5-h.p. turbine supplies the hydraulic accumulators necessary for operating the turbine governors. A traveling crane, capable of raising a weight of 15 tons, has been installed here for facilitating repairs and handling the machines. In front of the generating room is the transformer room, supplied with water under pressure. The turbines were furnished by Meyret-Brenier, Grenoble, and the electrical equipment by Brown-Boveri, Baden.

The turbines are of the horizontal-shaft type with a cylindrical distributing chamber, and are attached to the alternators by flexible couplings. Their speed is 300 r.p.m., and they take at full load about 4 cubic meters of water per second. Three of the turbines are furnished with automatic regulators and are supplied with compensating gates. The alternators are of the three-phase type, with revolving fields. Each absorbs at its shaft 1350 horse-power when operating on full load, with a power factor of 0.80. The generators give 3000 volts at 50 cycles per second. The direct-current dynamos which serve as exciters are two in number, and are rated at 150 horse-power each. The armature has a speed of 500 r.p.m. They are shunt-wound machines, and generate current at 115 volts.

The transformers raise the voltage from 3000 to 15,000 or 26,000 volts. These step-up transformers, to the number of five, have each an output of 1150 kilowatts. The cores are disposed in the same plane. The 3000-volt primary windings are subdivided on each phase into three equal parts, placed in series. This provides for the possibility of changing the connections for utilizing a voltage of 1000, by grouping the sections in parallel. The extremities of the secondary bobbins are attached to six terminals, placed on the transformer case, so that a simple movement at the high-tension switchboard will enable the connection of these coils to be made either in triangle or in star, the first giving 15,000 volts and the second 26,000 volts. The cores and windings are submerged in oil cooled by water circulating in a double worm. The weight of each transformer is about 9500 kilograms. A track running into the transformer room allows the transformers to be carried easily to the repair shop, where there is a 10-ton traveling crane.

The switchboards are three in number. They include all measuring apparatus, as well as those for protecting the station. The first is the intermediate tension switchboard; the second, the low-tension switchboard, and the third, the high-tension board. The intermediate tension board is placed on the ground floor between the turbine room and the transformer room. The low-tension board is placed on the second floor on an operating platform. The high-tension switchboard is placed at the middle of the switchboard room on the second floor. Back of the high-tension board are placed the horn lightning arresters, with liquid resistance for protecting the apparatus in the station. At the exit from the station, supplementary lightning arresters have been installed to increase the security. It has been the aim of the design to make the passage of lightning to the ground as direct as possible, with the object of protecting the station apparatus.

The bases of the turbines, alternators, transformers, all frames supporting the electrical conductors, in a word, all metallic parts in the installation, have been grounded by means of two wires, each two millimeters

FIG. 3.—TRANSFORMER ROOM IN CHAMP STATION.

in diameter, one connected to the water pipe and the other to a shaft of copper sunk in the tailrace.

The principal line of feeders is 30 km. (18 miles) long, and consists of six wires, each 7 millimeters in diameter, supported by metal poles common to the Societe de Force et Lenniere Grenoble et the Societe Hydroelectrique de Fure et Morge.

Current at 26,000 volts is distributed to the sub-stations, of which there are eleven. These sub-stations lower the voltage to 2000 volts, or 1000 volts, according to the locality. From these sub-stations secondary lines serve the stations of the subscribers. Certain industries use current directly at 2000 volts, but the majority prefer to lower the voltage to 120 by means of transformers furnished by the company. All of the stations are constructed in the same way, and consist of small Kiosks of masonry 3 meters square, in general surmounted by a tower which serves for the entrance of the primary lines and the exit of the secondary lines. The primary lines terminate at an air switch, then pass to a set of lightning arresters of the horn type, before entering the tower. The wires are then fixed to the terminals of a set of circuit-breakers similar to those of the generating station, and placed in niches of white marble. The secondary lines passing from the transformers are connected to a set of Wurtz lightning arresters, then to a set of circuit-breakers of the fusible type; and pass to the stations which they are called upon to serve from the tower.

The total efficiency of the station after a transmission of about 50 km. (31 miles) and a double transformation is 58 per cent. The Champ station is only intended to furnish electrical energy for motive power to the diverse industries installed principally in the valleys of the Fure and the Morge rivers. The rates for each h.p.-year are 125 francs ($25) per horse-power for a 12-hour day, and 150 francs ($30) for a 24-hour day load. The Societe Hydroelectrique has used a capital of 5,000,000 francs ($1,000,000) for this installation. The company has not made any lighting installations, as the districts traversed by its lines are already supplied by other enterprises for distributing electrical energy.

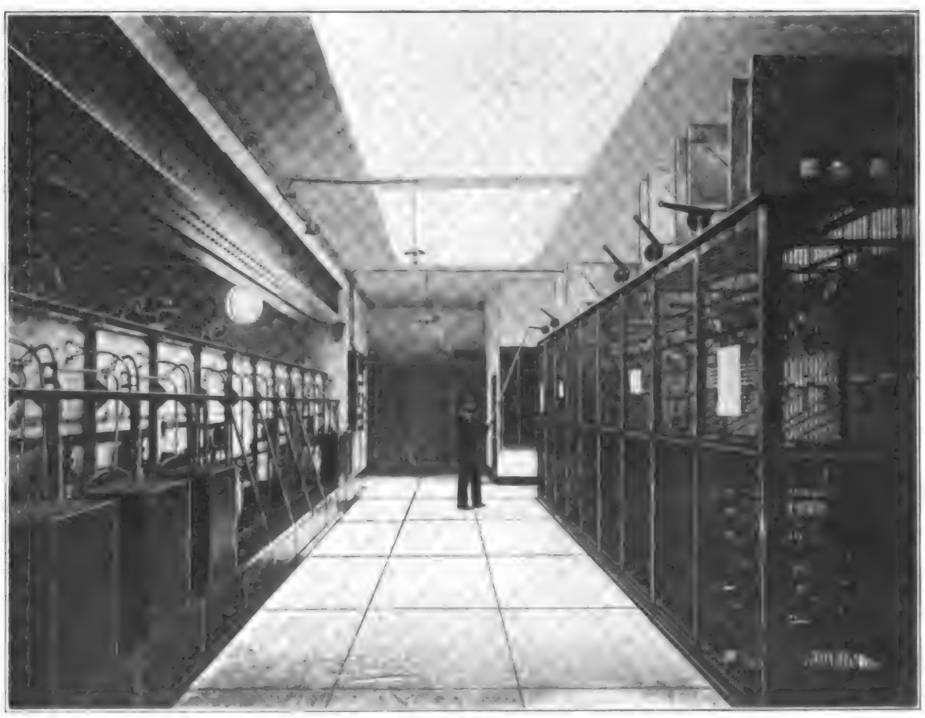

FIG. 4.—HIGH-TENSION SWITCHBOARD IN CHAMP STATION.

BOILER MANHOLES AND HANDHOLES.

BY R. T. STROHM.

Every steam boiler must be subjected to periodical cleanings, both inside. and outside in order to maintain its proper condition with regard to safety and efficiency of operation. For internal inspection and cleaning, some means of access to the inside of the boiler shell or drum is necessary. Consequently, boilers are fitted with manholes and handholes.

The location of manholes in a boiler shell should be such as to afford easy access to those parts requiring care and attention. In the plain cylindrical boiler, the manhole is placed in the head, which is usually bumped to make it self-supporting. In the return tubular boiler, there are usually two manholes, one being placed in the front head, below the tubes, and the other in the middle plate of the shell above the tubes and at the highest point of the shell. The lower one enables the inspector to examine the plates that are in contact with the furnace gases in operation, while the upper one permits him to inspect the condition of the braces and stays. In the case of water-tube boilers, a manhole is placed in the head of the steam drum, or in the head of each, if there are several drums. In boilers of the vertical type, the manhole is placed in the side of the central main drum, near the bottom, as in the "porcupine" boiler; or it may be omitted altogether, as in various other makes in which there is no necessity of entering to make examination of the condition of the shell; or in which the steam space or the water space are not large enough to admit a man. Handholes should be placed wherever deposits of sediment are likely to occur, if

these deposits cannot be easily removed through the nearest manhole. They are located in the water legs of vertical and locomotive boilers, in the heads of return-tubular boilers, and in the headers of water-tube boilers, opposite the ends of the water tubes, to which they give access.

The size of the manhole varies a little among manufacturers of boilers, but the average size is about 12 inches by 15 inches, the hole being elliptical in shape. Handholes are also elliptical, but they vary in size to a much greater extent than manholes. Thus, handholes may be found 9 inches by 14 inches, or 8 inches by 12 inches, and down to the common opening 4 inches by 6 inches, depending upon the size of the boiler and the location of the hole. The handholes opposite the ends of water-tubes in water-tube boilers are generally circular, especially when each tube has its own individual handhole. In case one hole gives access to two tubes, it is made oblong.

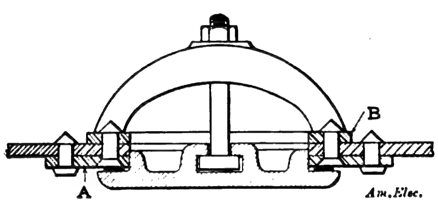

FIG. 1.

The cutting out of a section of the shell to give the manhole opening weakens the boiler, since it takes away a portion of the plate which would otherwise aid in resisting the forces set up by the internal pressure. Now, there is a greater pressure per inch of longitudinal seam than per inch of girth seam. That is, the boiler is more liable to rupture by splitting in a longitudinal direction than by tearing apart circumferentially. Hence, it is desirable to remove from the shell as little as possible of the metal which would strengthen the boiler along the line of greatest stress. For this reason, the manhole opening is so placed that its shorter axis or dimension is parallel to the longitudinal axis of the boiler, as in this position the shell is weakened least.

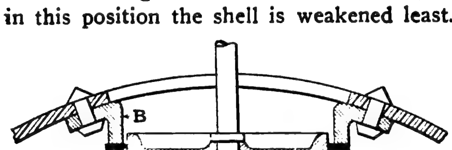

FIG. 2.

In case the manhole is placed in one of the heads its longer axis is horizontal, in order to enable a man to enter easily and not because the head is stronger with the hole in this position than it would be with the longer axis vertical.

To compensate for the loss of strength due to the cutting away of the plate, it is customary to use re-inforcing rings or their equivalent. The re-inforcing ring is simply a flat ring of metal riveted to the shell around the edge of the opening. The net section of this ring is made of such extent that its tensile strength will be at least equal to the tensile strength of that part of the plate cut away along the short axis.

The re-inforcing ring may be made of gun metal, wrought iron, cast iron or steel. The use of cast iron is not to be commended, however, for this ring must safely withstand stresses which tend to tear it into halves, and in tension cast-iron is a very unreliable and treacherous material. An ordinary form of re-inforcing ring, made of wrought iron, is shown at *A*, in Fig. 1. It is riveted to the inside of the shell by a double row of rivets, the row next the edge of the hole being countersunk so as to give a flat surface upon which the gasket may rest. Frequently an additional ring is used on the outside, as at *B*. In case two rings are used, their combined strength should be equal to or greater than that of the plate section removed.

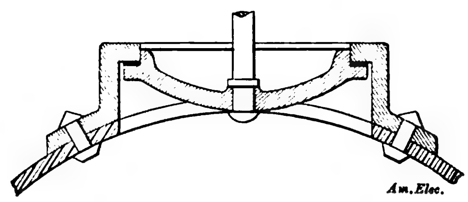

FIG. 3.

If a cast-iron frame or ring is used, it may have the form shown in Fig. 2, where the ring is shown placed on the inside of the shell. When the boiler is under pressure, the manhole cover, *A*, is pressed outward against the lip *B*, putting a compressive stress on the frame. Cast iron being very strong in compression, this is the safest form of frame made of this material. The fact that it is in tension laterally is the objection to its use. Another form of cast-iron frame but riveted to the outside of the shell, is illustrated in Fig. 3. In this style the metal is in tension in both directions; hence, the outside cast-iron frame should be avoided as far as possible. In a number of instances, outside frames of this shape are made of gun metal or wrought steel, these materials being amply strong in tension. Another method of re-inforcing manhole openings which is widely used is illustrated in Fig. 4. It is done by cutting the hole in the plate considerably smaller than the finished opening desired, and then flanging the edge, turning the plate inward, as at *A*, after which the edge is faced off nicely to form a bearing for the manhole cover. The ring of plate thus curved inward is relied upon to strengthen the plate properly.

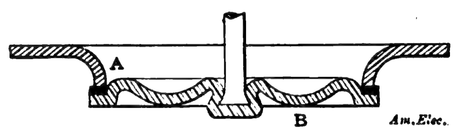

FIG. 4.

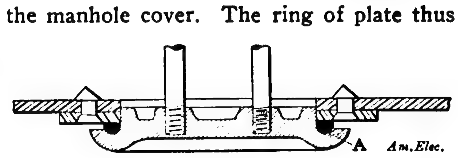

FIG. 5.

Usually handholes are comparatively small in size, and for that reason no re-inforcing ring is used in many cases, the handhole plate bearing directly against the plate. In the case of very high pressures, or very large handholes a single ring may be riveted outside the plate to compensate for the loss of strength due to the removal of material.

The covers of manholes and handholes are generally made of cast-iron, and they are held in place by the internal pressure when the boiler is under steam. However, it is necessary to have some means of securing them under all conditions, and so each plate is fitted with one or two bolts and yokes. These may be stud bolts, screwed into the cover, as in Fig. 5, or the plate may be drilled and the bolt riveted in place, as in Fig. 2. Another method, quite as common as either of the foregoing, is to cast the cover plate with a slot into which the head of the bolt is slipped, as illustrated in Fig. 1.

A form of cover plate which may be made either of wrought iron or steel is illustrated at *B* in Fig. 4. It consists of a piece of sheet metal which is formed to the desired shape by dies, under heavy pressure. The bolt fits into the dovetail slot at the middle, and cannot be pulled out by any ordinary force. This style of cover is very light, and as it is made of rolled material, there is little chance of flaws being present, which cannot be said of a cast-iron plate. The corrugations act as strengthening ribs, preventing buckling of the cover when under pressure.

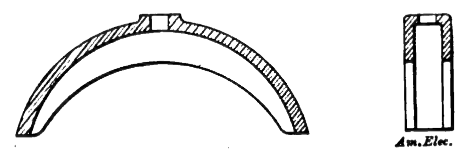

FIG. 6.

The yokes by which cover plates are held in place are made of cast-iron, to a great extent. In case the cover is of the form shown in Fig. 4, however, the yoke is made of the same material, being of the shape shown in Fig. 6; like the cover, it is formed by dies from a piece of flat plate. Where handholes are not re-inforced, it is not uncommon to find the yoke made so as to bear along the entire perimeter of the hole, as illustrated by Fig. 7, instead of at several points. as in the case of the ordinary yoke.

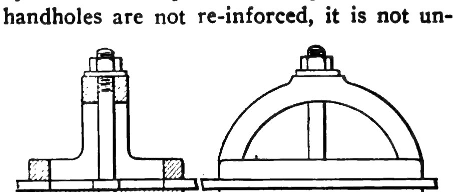

FIG. 7.

An ordinary cast-iron manhole cover has considerable weight, and it is no easy matter to hold it in place, and at the same time adjust the yokes and the bolts. To aid in placing it, wrought-iron loops or handles are frequently cast in the plate, by which it may be held and adjusted; the shape and location of these rings is usually as shown at *A*, *A*, in Fig. 8. The comparative lightness of the plate shown in Fig. 4 makes it unnecessary to provide any handles, which

is another advantage possessed by this type of cover.

Although the total steam pressure on a manhole or handhole cover plate is considerable, it is not sufficient to maintain a tight joint between the cover and the main shell.

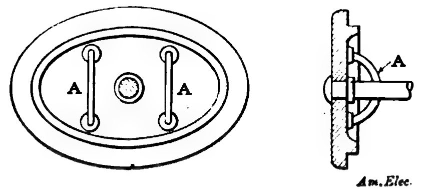

FIG. 8.

To prevent leakage here, gaskets of various materials are used. In Fig. 5 is shown the method of applying the gasket to the form of joint there indicated. A shallow recess is cast in the cover plate, into which is fitted a ring of gasket material of circular cross-section. When the yokes are put in place and the nuts tightened, the cover is drawn up against the re-inforcing ring, flattening the gasket as at *A* and making a tight joint.

A form of gasket widely used for this purpose is shown in Fig. 9. It is practically a heavy cord, made up of alternate layers of cotton duck and rubber, with a core of soft wire. It is sold in long coils, from which a sufficient length is cut when

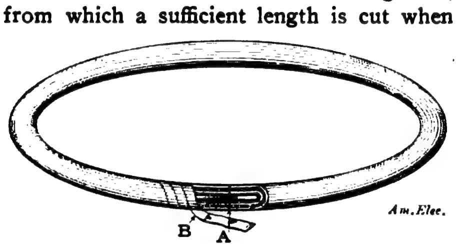

FIG. 9.

a joint is to be made. This piece is bent to fit the manhole plate, then its ends are cut so as to match nicely, as at *A*, and the joint is wound with tape, as at *B*, making a continuous gasket. Another style of gasket of somewhat similar construction consists of a small tube of Para rubber containing an insertion of brass wire gauze. This combination is encased in another layer of ordinary gasket rubber. Instead of wrapping the joined ends with tape, however, a short annealed copper sleeve or ferrule is employed, into which the ends

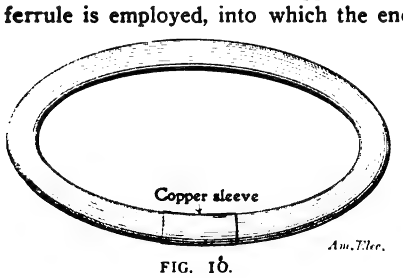

FIG. 16.

of the piece are forced until they meet, making the joint appear as in Fig. 10. The material for these gaskets varies from 3/8 inch to 5/8 inch for handholes and manholes, and may be obtained as large as 1 inch in diameter for extra large joints.

In case the flange of the plate or that of the re-inforcing ring extends inward, as in Figs. 2 and 4, to form a bearing for the cover, there is some danger of squeezing out the gasket. A form designed to prevent this action is illustrated in Fig. 11. It consists of two flat rings of rubber, *A, A*, between which is a soft metal ring of I section. The lugs on the metal ring pre-

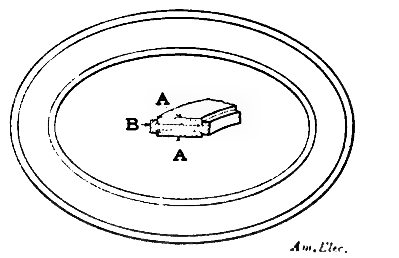

FIG. 11.

vent the rubber from being squeezed out entirely when the gasket is under pressure. The usual type of gasket, such as is used in connection with the manhole covers shown in Figs. 1, 2 and 3, is made of asbestos, rubber, rubber and copper, or metal alone.

If so desired, the cover plate may be made as shown in Fig. 12. A groove is cast in the flange, into which soft metal is poured and hammered. Owing to its plastic nature, this metal forms a good joint when the cover is properly drawn up, while the depth of the groove which holds it prevents its being squeezed out or blown out by the steam pressure.

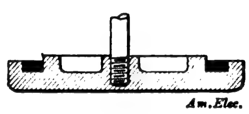

FIG. 12.

In most boilers, it is necessary to remove and replace the handholes and manholes frequently, and therefore the gaskets should be of such form as not to be easily destroyed by repeated breaking of the joints. It is well to give the gasket a coat of oil and graphite after it is put in place on the cover, so that when the joint is broken the gasket will not stick to the boiler shell. In replacing the cover, care should be taken to put it back in the same position that it occupied before it was removed, so that the same surfaces meet, in order to prevent leakage.

THE "PHANTOM" TELEPHONE CIRCUIT.

JAMES S. ROBINSON.

It is customary, between telephone exchanges having considerable toll business, to have order wires for the switching operators. When the distance is great, a special circuit called the "phantom" is sometimes used. This circuit should only be put on the best lines, as the least difference in balance will cause the phantom to be very noisy.

Fig. 1 herewith is almost self-explanatory. Repeating coils are placed in trunks 1 and 2, and taps are taken out of the middle of the line side of each. These taps are connected to one-half of the secondary of the double-wound induction coil and compound receiver.

The double wound head 'phone is connected to two plugs which go in the jacks marked *R*. It will be noted that one winding of the receiver is in the phantom circuit at all times. The distant operator has only to press her button switch marked *B* in order to carry on a conversation.

The switch, *B*, is shown in its normal position. The transmitter is then connected to the regular primary winding, the secondary of which is connected to the keyboard. Pressing switch, *B*, throws the transmitter on the primary winding of the special circuit and the operator can converse over the phantom.

Ring down phantoms are used in practically the same manner. It is not necessary, however, to have the special double induction coils and receivers, as the phantom is carried to jacks and drops on the board. When the phantom is not in use, the

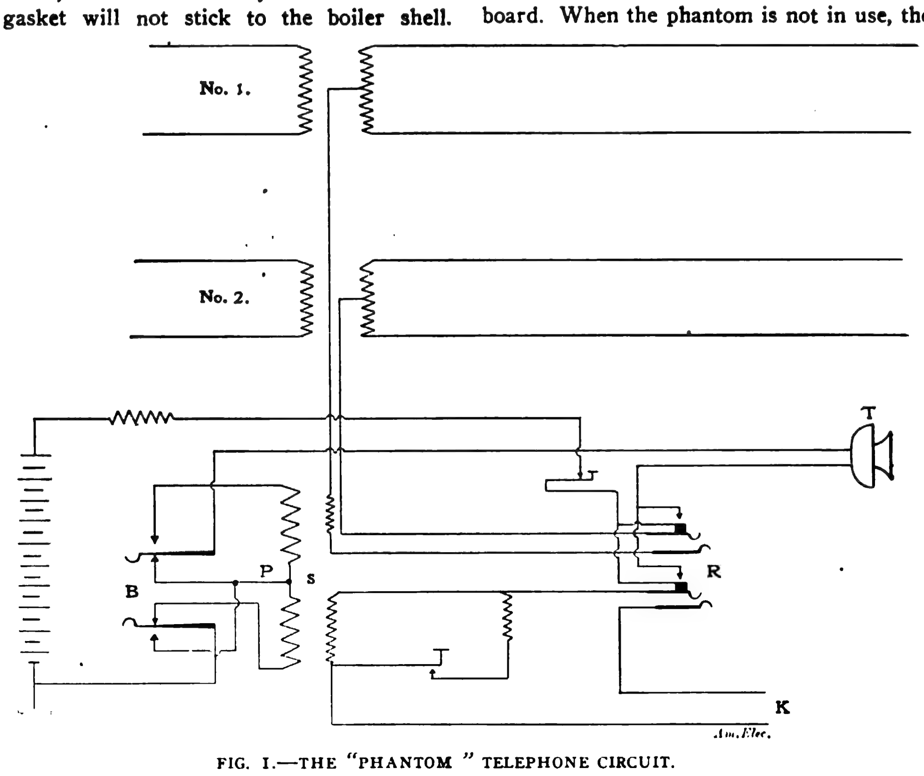

FIG. 1.—THE "PHANTOM" TELEPHONE CIRCUIT.

coils are cut out and the trunks cut straight through in the ordinary manner.

The installation of the phantom circuit does not entail any great expenditure, and the up-keep is practically nil.

THE MOTOR EQUIPMENT OF EXISTING MACHINE TOOLS.

BY GEORGE T. HANCHETT.

When a machine tool and an electric motor are designed together, well known principles of machine design can be applied and a uniformly satisfactory result is usually produced. Occasionally, however, the equipment of belt-driven machine shops presents itself, and the practice that it is wise to follow in such cases sometimes differs materially, since many considerations enter to influence the design. Briefly, the problem is to select a standard size of motor and then decide upon means of mechanical connection to the tool to be driven.

As a major premise it is assumed that rigid mechanical connections are the only ones to be considered. In the opinion of the writer one of the principal advantages of direct electric driving in machine tool work is that when electrically equipped the tool can be forced far beyond its belt capacity. This advantage is sacrificed when a belt connects the motor and the tool. Labor is far more valuable than kilowatt-hours, and this makes it expedient to resort to individual drive, when from a point of power economy, group driving might be preferable. Furthermore, the possibilities of economical shop arrangement for maximum production are favored materially by individual motor drive, and it is unquestionably wise to carry this method to a further degree than power considerations alone would suggest. Hence, the present article deals with cases of individual drive and geared connections.

Before selecting the motors and designing the parts the following data of the machine tool should be secured: Maximum speed of the driving pulley; minimum speed of driving pulley; diameter and face of largest driving pulley. This suffices to determine the power of the motor. The datum for the mechanical application consists of an accurate drawing of the entourage of the driving pulley. Full details should be included, for when the motor is selected and the drawings of the brackets are begun, it will be found that there are many things which interfere, and quite as many more of which important advantage can be taken.

The selection of the motor is, of course, of vital importance. Its speed should be high, at least 1100 r.p.m. or 1200 r.p.m., for if lower speeds are adopted the motor is bulky and unduly expensive, and its application becomes more difficult. The motor should have at least torque enough to skid the belt, and sufficient speed to drive the pulley at its maximum velocity. This fixes its minimum power. Further increase in the power of the motor depends upon practical considerations, which will presently be discussed.

The skidding pull on a single belt may be taken at 30 pounds per inch of width. A double belt may be credited with a pull of 60 pounds per inch. These are large values and are only true if the belt has a firm grip on a pulley of large diameter, and is well dressed, free from oil or grease and pulls evenly. As these latter conditions almost invariably prevail to a greater or less extent, a motor based on these figures will always outdo a belt by a comfortable margin. The method of calculation differs with the type of control to be employed, of which there are two great classes, armature control and field control. With armature control the armature voltage is varied by means of a multiple-voltage system, armature resistance, or other expedient. A third class of control is the mechanical, which is often worthy of consideration in the case of a constant-speed motor, the variable operating speeds being obtained by means of mechanical gearing or belting.

In order to discuss these methods intelligently, it is best to select a standard problem which will illustrate them. Suppose one has to deal with an engine lathe of which the following is the data:

Maximum speed of driving cone . .	200 r.p.m.
Minimum speed of driving cone	33⅓ r.p.m.
Diameter of largest driving cone	1.5 ft.
Width of double belt	4 ins.

The following formula will be useful:

$$H.p. = \frac{\textit{Belt pull} \times \pi \times \textit{Diam.} \times \textit{Max. speed}}{33{,}000}$$

In the present case the result will be:

$$H.p. = \frac{240 \times 3.1416 \times 1.5 \times 200}{33{,}000} = 6.8544$$

To adopt this size of motor would be to assume that the manufacturer of the machine had designed the cone to produce by belt pull sufficient power to bring the various parts of the machine up to their safe working stresses. It frequently happens, however, that a machine is inadequately belted, and that the tool is capable of using more power than the belt can provide. It is not, however, wise to overpower the tool, for it may be safely assumed that whenever this is the case the tool will be forced to the limit, and power sufficient to rack the machine to pieces should, of course, be avoided. However, a lathe equipped as above will at its lowest speed do better than when belt-driven, and on the highest speeds the improvement will be very great, for by armature control the power increases with the speed, whereas by belt control due to the reduced diameter of the pulley belt adhesion is not as good and power decreases with the speed. Therefore, the foregoing formula is usually applicable in cases where the speed is controlled by varying the armature voltage.

If the speed is to be controlled by varying the field, the power of the motor is definitely fixed and the results are influenced by different conditions. In such a motor the horse-power is constant and the torque varies; being a maximum at the lowest speed of the motor. In fact, such a motor duplicates the performance of the belt, as it is stepped from cone to cone, so that theoretically field control is a very beautiful and attractive means of solving the variable-speed problem. The formula in this case becomes:

$$H.p. = \frac{\textit{Belt pull} \times \pi \times \textit{Diam.} \times \textit{Min. speed}}{33{,}000}$$

and in the foregoing problem

$$H.p. = \frac{240 \times 3.1416 \times 1.5 \times 33\tfrac{1}{3}}{33{,}000} = 1.1424$$

This value, it will be noted, is exactly one-sixth of the value obtained by the armature control system, and is the power exerted by the larger motor on its lowest armature voltage, which would, of course, be one-sixth of its maximum voltage, sufficient to skid the belt at the lowest speed. It is, however, to be noted that this motor must possess peculiar characteristics. Its field must be so designed that it is capable of being weakened so that the motor will run without injurious sparking at a speed six-fold greater than it did before. This limitation on the design of the motor requires a field of considerable range, unusual precaution in commutator design, and other considerations, all of which compel the designer to make the motor more bulky, the result oftentimes being a machine quite as bulky and as expensive as the 6 horse-power competitor. Moreover, this machine does not increase its power with its speed as does the armature-controlled motor. Although it will do a little better than the belt on the high speeds, due to the defective action of the belt itself on higher speeds, the improvement will not be anywhere near as marked as in the case of the armature-controlled machine. Furthermore, in lathes and tools possessing back gears, the heavy cuts, the exhibition performance, at it were, are frequently made on the highest speeds with the back gears in, and when the engineer considers that he has, beside his own satisfaction, that of his client and of the machine operator to consider, both of whom are looking for great improvements, due to the outlay they have been compelled to make, it will be safer, should he adopt field control, to put a considerable margin on the power that this formula gives him.

Having selected the system, and, by the aid of the formulæ, computed the various sizes of motors which the many machines in the shop demand, a list of standard sizes must be consulted in order to select the machines themselves. This in itself is a commentary on the value of calculations to the fourth and fifth decimal place. A 6.854-h.p. motor is not a standard size, and even should one admit that this value is obtained through accurate theoretical assumptions, its accuracy in practical application is destroyed since one must use the nearest standard size. In this connection it is well to mention that the choice of size is done almost automatically, the engineer being irresistibly inclined to take the standard size of motor whose output is slightly greater than that found in the computation.

The problem must, however, be viewed as a whole, because the accumulation of a large number of different sizes in one shop

would be very unwise. The number of different sizes should be a minimum and all parts should be interchangeable, so that a minimum supply of reserve parts will protect the entire shop. For this reason it

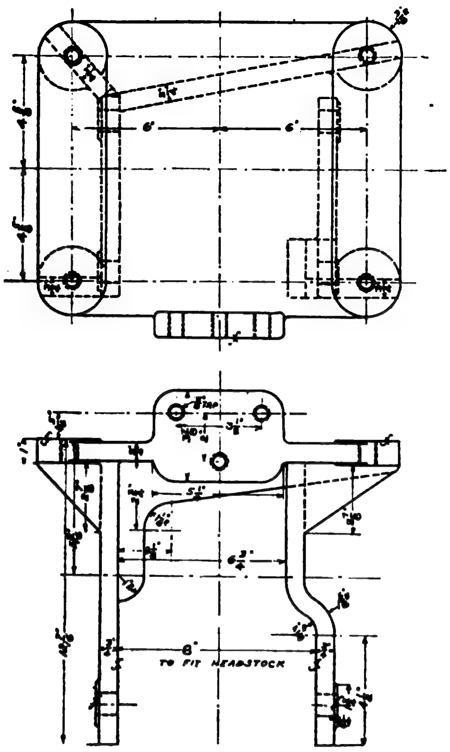

FIG. 1.

is often wise to select a 2-h.p. motor for a lathe which calculation indicates only needs 1½ horse-power, and it is sometimes wise to skimp the calculations a little in cases of lathes or tools which are occasionally used on light duty and adopt a size a shade lower, and thereby avoid an odd motor. It is here that good judgment must be displayed, and the previous duty of the tools must very largely influence the decisions.

Having selected the motors, their connection to the tools becomes the next consideration. In the opinion of the writer belting is only permissible in the case of small speed lathes where it would not pay to go to any expense, and where, moreover, the largest duty of the tool is done on the high speed, the belt adhesion being poor and advantage being taken of this by putting the belt on the largest cone.

The problem is one of machine design and no hard-and-fast rule can be laid down. The following remarks, however, may be helpful: The transmission must be first fixed upon. This must be either by gears or by the well-known forms of silent chain. Almost every machinist has had the trouble of having the lathe belt jam underneath the cone. Therefore, if the cone is to remain upon the lathe, a silent chain, unless abundant clearance is available, is inapplicable, and the problem is best solved by the application of gears. The motor should be supported on a bracket, preferably of cast iron, and the writer has found it convenient to employ idlers between the motor pinion and the gear which drives the lathe. A cup-shaped, toothed annulus, as shown in Fig. 1, may be conveniently employed and securely fastened to the cone by large screws. The width of the gears and pitch should, of course, be calculated with reference to the material of which they are made and the well-known torque formulæ. In designing the casting many troubles will be encountered. It is well to remember that the back gear shaft occupies a different position when the gears are out than when they are in. When the lathe is plentifully equipped with various gears for screw-cutting purposes or for driving feed rods, it may be found that while the casting will fit one combination of gears, another combination will interfere with it, so that the reserve stock of gears and their application to the machine should be carefully examined before finally deciding upon the dimensions of the casting. The writer has found it convenient to mount the idler bearing on a separate plate, which is bolted upon a finished plate on the main bracket, and which, when finally fixed in position, can be permanently secured with dowels. A few sixteenths for adjustment one way or the other should be allowed, for a founder's conscience with reference to dimensions is quite as warped as his production.

The speed of the gear teeth is an important problem, for even the best cut gears will be noisy if a certain speed is exceeded, and this speed seems to be about 750 ft. per minute. Beyond this speed it is wise to

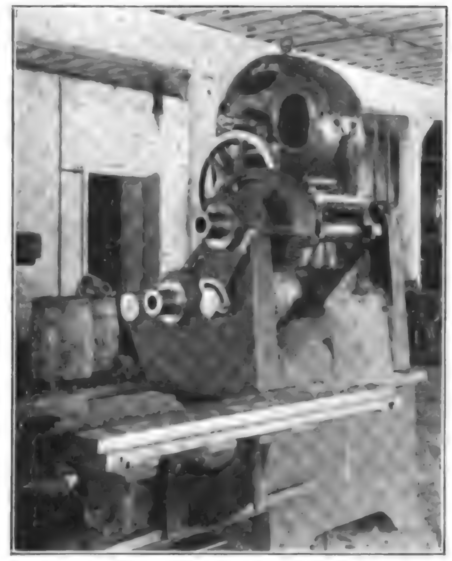

FIG. 3.

resort to rawhide gears, and the advantage of the idler becomes apparent, for a single rawhide idler will give noiseless contact between all of the gear surfaces. The application of the idler bearing to the main casting is shown in Fig. 1 and a lathe equipped in such a way is illustrated in Fig. 2. Frequent advantages are sometimes offered in lathes of peculiar design. In Fig. 3 is illustrated a lathe of the double-spindle variety, where the upper spindle was a serious obstacle to the mounting of the bracket. The obstacle was turned into a positive advantage by simply providing the bracket

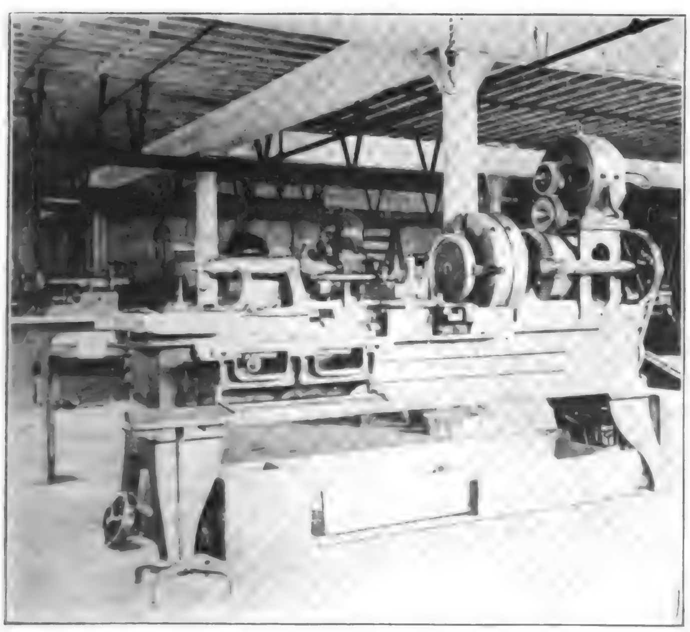

FIG. 2.

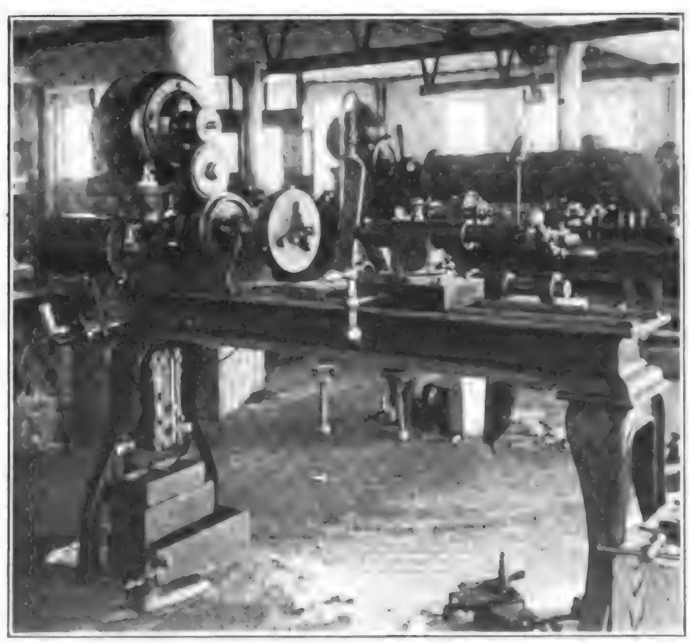

FIG. 4.

with bearings in a manner, somewhat after the fashion of suspending railway motors. The speed of the spindle was so low that the simplest lubricating device sufficed to keep the bearings cool. In the application of motors to brass lathes with special screw-cutting arrangements, which are more or less obstructive when motor driving is concerned, great care has to be

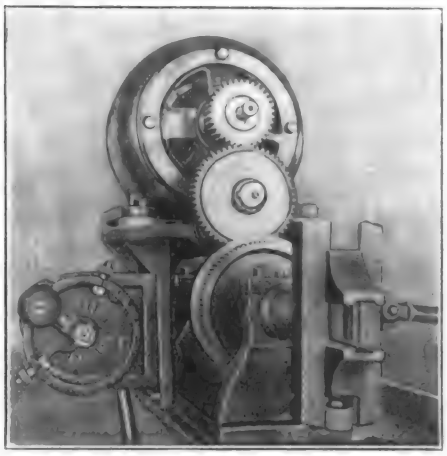

FIG. 5.

taken to avoid the gears and studs. With a case as shown in Figs. 4 and 5 it will be at once seen that to avoid the back and screw-cutting gears is a problem calling for ingenuity on the part of the draughtsman. In the application of brackets to lathes it will usually be found best to obtain the levels of the brackets by equipping their feet with small pins, which can be upset to any desired height with a few strokes of the hammer and lined up in the lathe bed. Once in line a bracket can be securely doweled and bolted to the head stock.

In applying motor drives to shapers, planers and millers, the problem is almost always a special one. Fig. 6 illustrates a Stockbridge shaper equipped with a motor and driven by means of a silent chain, the cone pulley having been removed for this purpose. Here abundant clearance was available and there was no danger of jamming the chain between the driving pulley and its surroundings, and the drive is a remarkably quiet one. In the case of milling machines and shapers, and planers which require two pulleys revolving in opposite directions, the problem is always special, and various solutions thereof are shown in Figs. 7 and 8.

A drill press illustrates a case of variable-speed from a constant-speed motor obtained by means of belts. To figure the power of the motor in this case the same formula that applies to field-controlled motors may be employed, but the resulting motor runs at constant power and speed, and therefore no extraordinary designs for wide speed variation need be employed, as that is accomplished by the belt. Care should only be taken to have the motor sufficiently powerful to skid the belt in its most adhesive combination. Any further power of the motor is superfluous.

The arrangement of the controller on the machine tool is also a matter which requires careful thought. It is perhaps one of the first things which the operator who uses the tool will criticise. The average "belt-driven machinist," if that term may be coined for the purpose, will, when transferred to a motor-driven tool, very frequently claw the air for an imaginary belt-shifter when the tap is about to the bottom or the thread tool is approaching the shoulder, and will usually succeed in breaking both tap and tool. The result is more or less forceful language and a general condemnation of the inconvenience of the system of control, and in order to reconcile and please him it is desirable to place the controller in a convenient place. In lathe work the writer has found it convenient and expedient in the case of short lathes to mount the controller on the bracket which supports the motor, as shown in Fig. 5. This is convenient for the machinist, provided that the lathe is not too long. In the case of long lathes the only place for the controller handle is on the apron. Various devices may be employed to bring it there. One of these is illustrated in Fig. 9, in which a splined rod runs under the apron parallel with the feed screw. The controller is placed at the end of the lathe and underneath it, and connection is made with the splined spindle by means of an ordinary bicycle chain, the ratio between the sprockets being so chosen that the angular motion of the lever for complete control of the motor is not too great. For a shaper, planer or drill press the controller position is of course fixed by circumstances, as these tools vary widely in their construction.

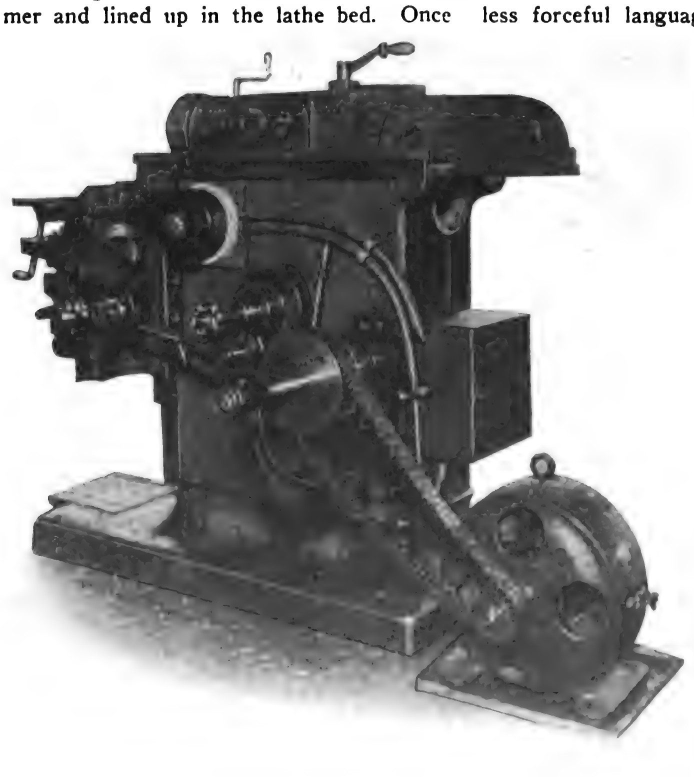

FIG. 6.

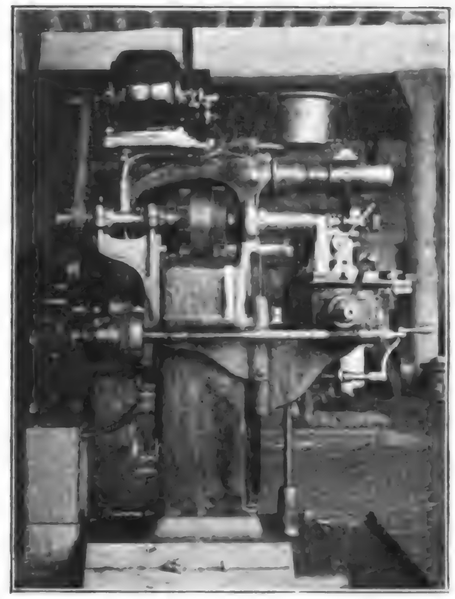

FIG. 7.

Figs. 6 and 7 illustrate methods which have been found convenient. In the case of tools which are used for steel work, particularly those for die making, the speed control must be very close. In the case of armature-controlled machines, the writer has found it convenient to equip them with rheostats which will provide a small amount of control by field variation. Almost any good standard motor will permit of enough variation by field control to bridge the gaps between notch and notch, and the combination, therefore, gives a very great number of speeds. It is, however, best to avoid this arrangement except in cases where it is absolutely necessary, for a machine tool, like a trolley car, should have as few unnecessary devices upon it as possible.

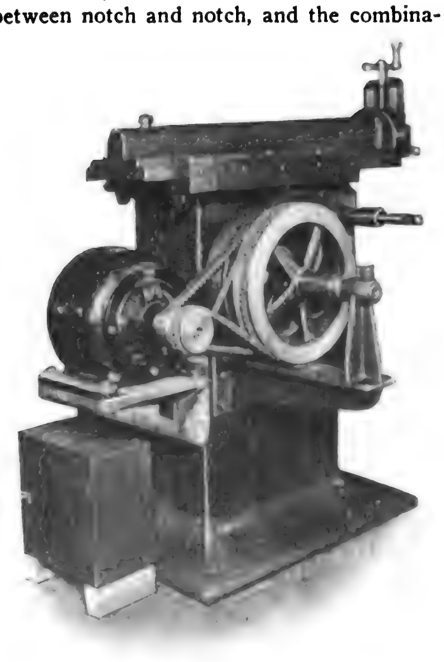

FIG. 8.

It is very difficult to educate the machinist to avoid starting a machine tool with a single motion, as in the old-time belt shifter fashion. It is a problem in human nature and not engineering. On a broad general principle the motors and the system of control should be selected so that the controller can be thrown to the desired speed in one swoop. For this reason it has been found convenient to equip the controller with stops so that the machinist can start his lathe by simply pushing his controller around as far as it will go. Such a system of stops is illustrated in Fig. 5, and has been found convenient for the machinist who, when he is busy with his work, has no time to select his speed, but simply pushes his controller handle one way or the other. This is of great convenience in thread cutting. Since machine tools are usually handled in this way, the writer is inclined to favor systems of armature-voltage control. Field-control systems, give trouble when brushes and commutator are neglected and vicious switching from full speed ahead to full speed reverse is practiced. In such cases

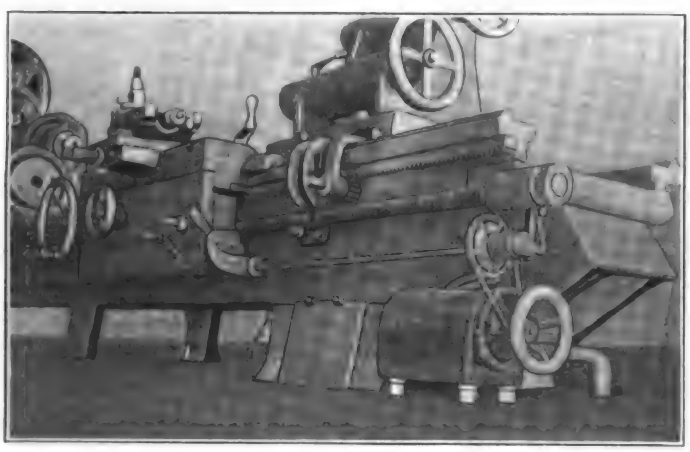

FIG. 9.

salvation from commutator pyrotechnics obtains in a field of maximum strength.

The application of circuit-breakers to machine tools is one on which there are many opinions and which deserves careful consideration. On heavy powered machine tools there is no question but what they are a useful check on unwise controller manipulation. In small machine tools, however, the writer has found a fuse of ample protection. A small motor will resist momentary surges of current much better than a large one, and as the motor has only intermittent work, the heating obtained through such flushes of current is not serious. Moreover, the losses in the variable-speed motor are never a maximum, for when the speed is high the I^2R loss is usually low, and in cases of armature control, when the speed is low, the iron losses are materially reduced. Therefore, an armature so arranged can stand much more punishment, and in small motors, fuses of 100 per cent. overload capacity are found very satisfactory.

The switch which controls the motor, should, in the opinion of the writer, be substantially boxed in. If it is exposed to flying metal in a machine shop there are too many opportunities for a short circuit.

AUTOMATIC BLOCK SIGNALS.

BY RALPH SCOTT.

Normal Clear Signal Mechanism.

A part elevation and part section of the mechanism employed in one form of the Union Signal is shown in Fig. 51. This mechanism consists of the motor *D*, which is geared by a small pinion to the large gear *W*, the latter being protected by a guard *V*. The pinion of this large gear engages with the smaller gear wheel *F*, which latter is mounted on a shaft that carries a small sprocket wheel, over which passes the chain *I*. The function of this chain will be shown later.

The signal boards are connected respectively to the rods *Q* and *S*. These rods are given motion by the pivoted members *E*, which carry electromagnets *U*. The cores and winding are shown in the sectional part at *G*. The armatures of these electromagnets are connected by links to the pivoted cam-shaped pieces *N*. The movement of the chain of levers which operates *N* also produces a number of other conditions which will be described later.

Dash pots, *D*, serve to check spasmodic movement of the arms, *E*, which latter are of a very heavy construction, and, consequently, require good damping means to prevent injury to the moving system. Mounted upon the same frame as these dash pots are the binding posts, *P*, which facilitate the various connections of the electrical devices employed in the signal mechanism. The motion of the piston of the dash pot which is connected to the home board, operates, by means of the lever, *C*, a current reverser, *J*.

This current reverser consists of a number of pivoted contact pieces rigidly connected to, but insulated from, the lever *H*. These contact pieces make connection with the flexible spring pieces *M*, which latter are connected to the binding posts *L*.

Upon the stationary bars *K* are mounted the insulated spring pieces *A*, which are brought into contact by an insulated piece *T*, carried upon a pivoted member *R*.

Another similar piece is also pivoted, and is operated by the distant members *E*. The purpose of these contacts is to make connection according to the position of the member which operates the board, as has already been shown in the circuit diagrams in Fig. 50.

A more detailed view of the mechanism which directily and indirectly causes the signal arms to assume their clear or danger position is shown in Fig. 52. Carried upon the chain *a* is a roller *e*, which engages with the pivoted member *i*. The

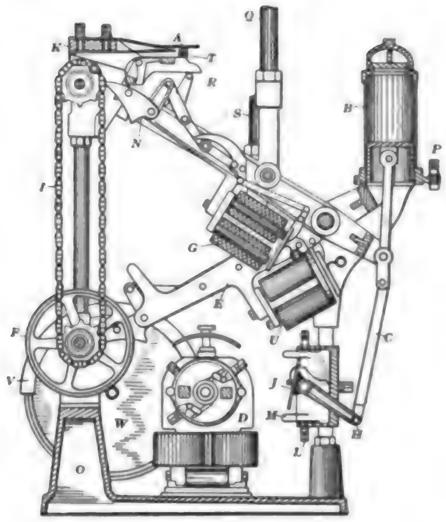

FIG. 51.

position of *i*, which is carried on the arm *m*, depends on the position of the armature of the relay *b*.

When current is passing through this relay, and its armature is attracted, the cam piece *h* moves the train of levers and throws *i* so that the end engages with the rollers *e*. If the chain *a* be moving it will,

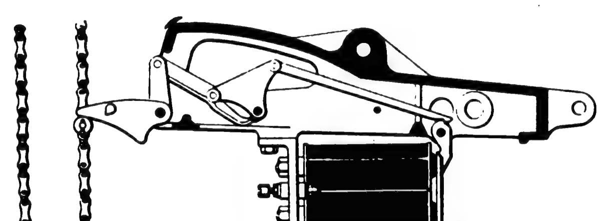

FIG. 53.

therefore, cause motion of the member and thereby moves the semaphore, which is connected to *j* by the rod *d*, the dash pot rod *g* preventing the motion from being too sudden. If, however, the relay is not energized, *e* will not engage with *i*, and thus prevent motion from being imparted to *d*, even though the signal motor be running.

Another form of this mechanism which

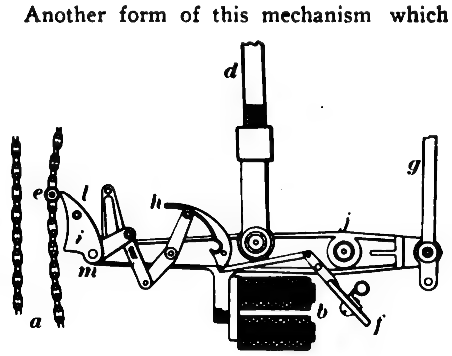

FIG. 52.

is much more reliable in its action and represents most up-to-date practice is shown in Figs. 53, 54 and 55. In Fig. 53 the relay is energized, and attracts its armature, which engages with the latch as shown. The moving chain causes the roller to come

into contact with the pivoted members, thereby throwing the signal to the clear position. If now the magnet be de-energized by the cessation of the track circuit current, the latter releases its hold, and,

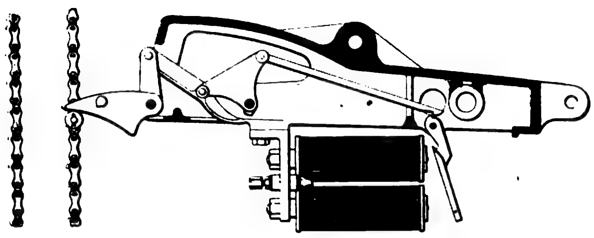

FIG. 54.

consequently, allows the signal to assume the danger position shown in Fig. 54.

The final position of the mechanism is shown in Fig. 55, the signal remaining in this position. After the roller has become disengaged with the cam piece the weight of the latter causes the latch bar to again engage with the relay armature. This engagement being, however, of sufficient resiliency to cause a disengagement when current is not passing through the relay on a further motion of the chain.

Normal Clear Relays.

In Fig. 56 is shown a neutral or slow-releasing relay, which is shown diagrammatically at *I* in Fig. 50. This relay is designed to secure a slow release of its armature after the energizing current has ceased. This relay is necessary, and must be included in series with the semaphore magnet or motor to prevent the opening of the signal circuit during a momentary reversal of current, which occurs on the movement of the polarized armature of the relay controlling the section to which the

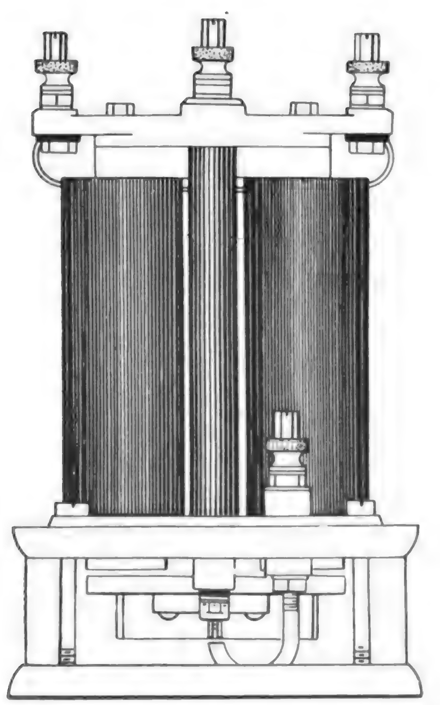

FIG. 56.

semaphore mechanism is connected, as is the case with the wireless track circuit system.

The slow release of the armature of this relay is effected by using a very long magnet core wound with a large number of turns of wire, thus giving a high self-induction, which prevents demagnetizing for a length of time sufficient to prevent the circuit being opened on the momentary reversal of current. With such a relay, a very high resistance is desirable, so that but a small magnetizing current is required. The residual magnetism, combined with that resulting on the inductive discharge,

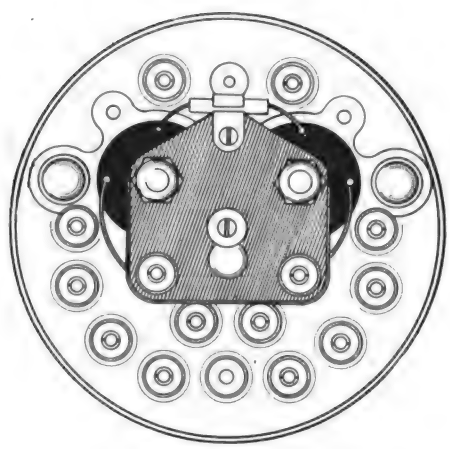

FIG. 57.

maintains the magnetism for a comparatively long interval of time.

A polarized relay is shown in various sections and elevations in Figs. 57, 58, 59 and 60.

Fig. 57 is a plan view, showing the arrangement of the binding posts for making the external connections.

Fig. 58 is a part elevation and part sec-

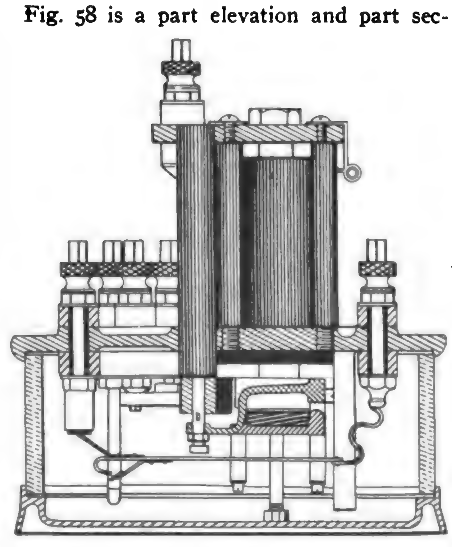

FIG. 58.

tion showing the arrangement and construction of the pivotal bearing for the polarized armature and the arrangement of the neutral armature and its contacts.

Fig. 59 is a view taken beneath the instrument showing the arrangement of the polarized armature *b* and the polar contacts *a*, which are mounted upon, but insulated from, the armature.

Fig. 60 is an inverted view which shows

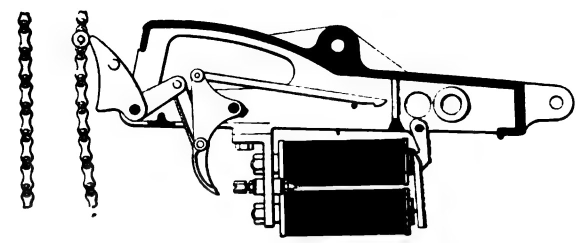

FIG. 55.

the arrangement of the neutral armature and contacts and also showing part of the polar contacts.

By referring to these illustrations, it will be noticed that the armature is pivoted very

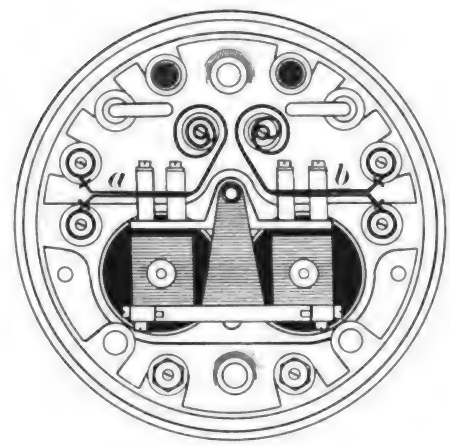

FIG. 59.

closely to the magnetic field, the contacts being at the end of comparatively long prongs, so that, while a very short stroke is given to the armature, a very wide opening to the contacts is given. The reason for this is to keep the armature itself within the range of a very strong field, as soon as the magnets are energized. The armature, however, is not too close to cause any evil effects from residual magnetism.

The armature pivots themselves are sup-

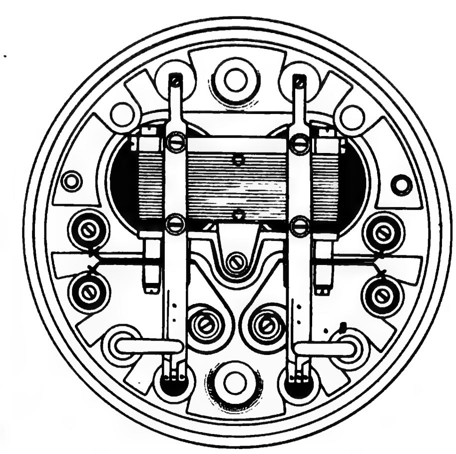

FIG. 60.

ported by the pole pieces, so that the armature is always kept the same distance from the poles, rendering unnecessary any further adjustment. The bearing of the polarized armature is comparatively large, which

prevents any binding action due to any uneven wear which may occur. The neutral armature is located below the polarized armature and in a plane perpendicular to that of the latter.

The contacts made by the polarized armatures have a scraping motion, which serves to keep them continually perfect. By noting the connections effected by the motion of this armature, which causes the contacts to shift alternately to the four contact posts, these contacts being connected to two stationary posts, the manner in which current reversal is effected will be readily perceived. The contact fingers of the short flexible contact spring are fastened to their free ends, the reason for this arrangement being a maximum amount of sliding with a minimum armature motion.

The contacts are of carbon and platinum, to prevent oxidation. The contact arms are connected to the binding posts by means of thin strips of copper, which have great flexibility, and prevent interference with the adjustment of the relay. All contacts and moving parts are enclosed in a glass compartment, to prevent accumulations of dust from effecting these contacts.

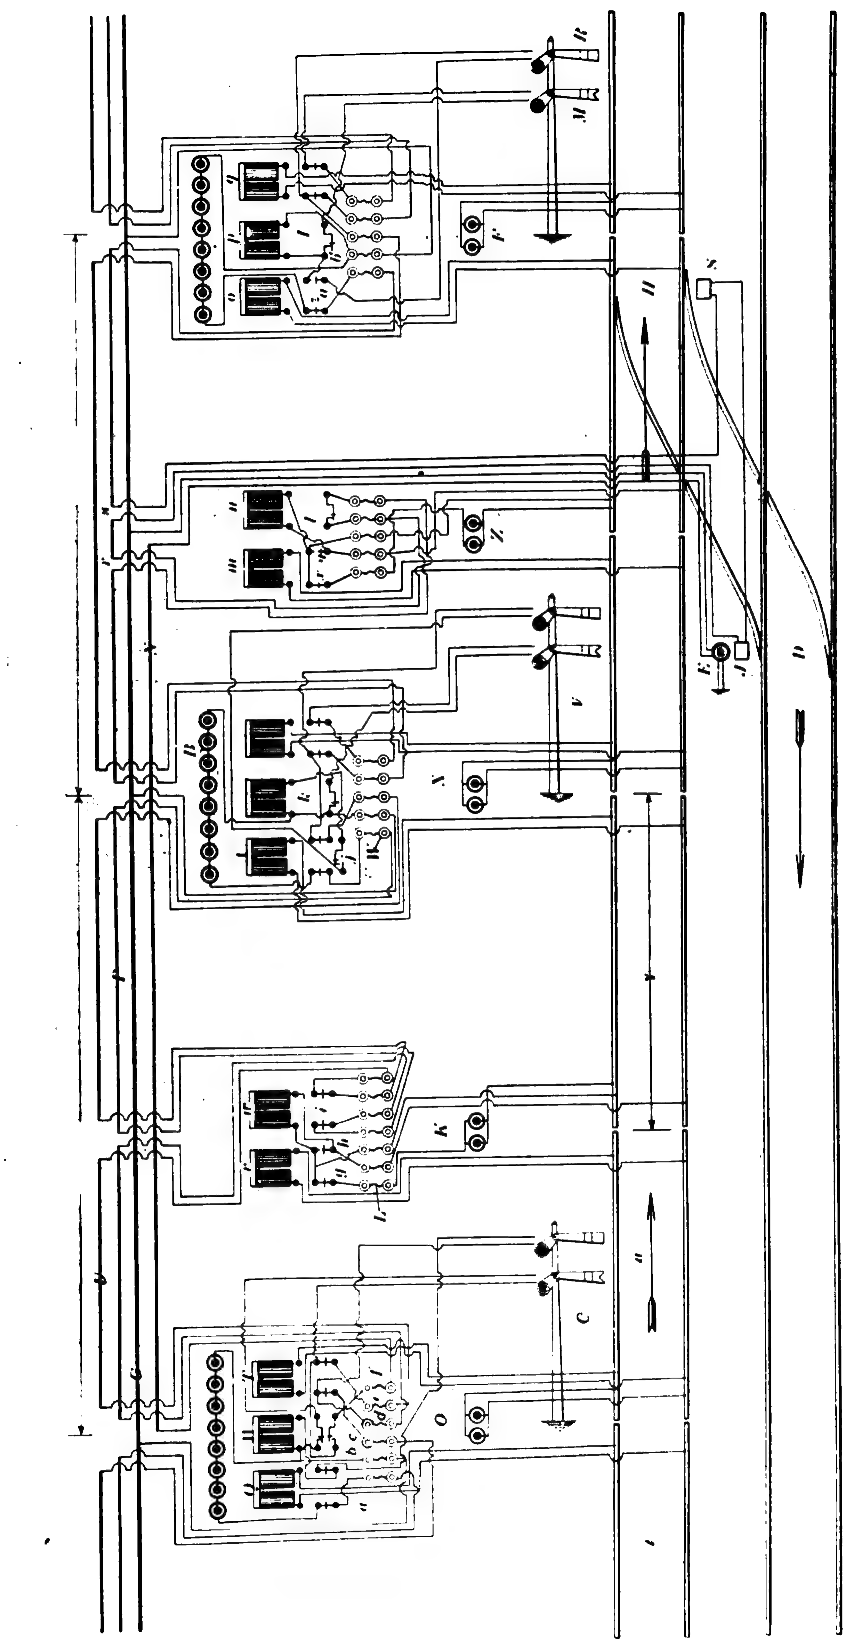

FIG. 61.—DIAGRAM OF COMPLETE NORMAL DANGER SYSTEM.

Complete Normal Danger Circuits.

Having now described the various forms of simple, normal, danger circuits giving protection against various occurrences, the description of a signal system which gives every protection that is possible for any system to give, namely, against an open rail, open switch, train in the block or defect in the signal apparatus, follows:

In Fig. 61 such a system is shown, line wire in this case being used. The distant wire which operates indirectly the distant board of all the signals is *U*. *P* is the home wire, *G* the common wire, and the indicator wire is *N*. *O, K, X, Z* and *F* represent, respectively, five cut sections which are each one-half mile apart, this distance being shown at *Y*.

The block of each of the signals *C* and *V* contains two cut sections, part of one of the sections of the signal *M* being also shown. On account of the different connections employed in each cut section it will be necessary to describe these specifically.

Beginning at section *O*, which is a signal section, there is the row of connecting posts *a, b, c, d* and *f*. *a* is connected to one side of the signal battery and also to the incoming home line wire. The connection to the signal battery is through a normally closed armature contact, which is opened when the relay *G* is de-energized, which will be the case when a train is upon section *t*. When this occurs, the first signal in the rear of *C* will be held in the danger position even though a train be approaching it.

The post *b* is connected to the common line wire, to one side of the block signal battery and to one side of the relay *W*. When the armature of the latter is in the upper position, this post is also connected to the distant board of the signal *C*.

The signal battery has thus one side connected to the common wire. This is the case with every signal, as will be evident from an inspection of the posts at *V* and *M*. Post *c* is connected directly to the home board *C*, to the post *d*, through one of the armature contacts of the relay *t*, and to the incoming home wire.

Post *e* is connected through the other armature contact of *T* to the distant board of *C*, to the lower normally opened contact of the relay *W*, and the outgoing distant wire. *f* is connected to the other side of the normally opened contact of *W* and to the indicator wire. *W* is energized by current passing in series with the other signal mechanism, operating the home board of the signal *C*. When this occurs, the battery becomes also connected to the distant board by the action of the upper armature contacts. The relay is consequently energized until the train occupies the section *u*. A train in this section will, it is also evident, short circuit the relay *v* in the relay section *K*.

The contact *g* on this relay's armature is normally closed while *h* is opened. When *h* is closed, the track section *Y* is short circuited. *g* serves the purpose of connecting the track battery *K* to the section *Y*. When this contact is open, the relay *A* at the signal section *X* is open. Thus, there is in this

combination essentially a track circuit system such as is shown in Fig. 37.

The normally closed contacts of the relay w are connected respectively in series with the home and distant line wires. Hence, when the battery K is not connected to the section U, or when the relay v is short circuited, the home and distant line wires will be broken. As will be seen, the contact h short circuits the relay w when closed. g and h, therefore, perform five functions, each of which is outlined above.

At L is shown, in diagrammatic form, the protection against high potential discharges or destructive foreign currents. This consists of choke coils and fuses.

At section X another signal, V, is shown. The signal battery V is connected to the first binding post W, the other side of this battery and the common line wire being connected to the second post. This section is similar in connections to section O except that the central relay has but one cross connected contact, K, which is normally closed. J connects one side of the signal battery to the central relay, and is normally open.

Section T is the relay section, and also contains two switch instruments and a switch indicator, these being placed at a main line crossover, the home line being broken at r and s, and in series with the various devices.

Relay m, through its contacts, x and y, controls the connections of battery z to the track. Contact l of the relay n virtually closes the home wire at r, and y in its operative position short circuits this relay. The indicator line wire N passes to the switch indicator E, the other side of this indicator connecting to the common line wire, this being connected to one side of all the signal batteries, the connection of the other side of these batteries depending on the interconnection effected by the various relays, within two signal blocks from the instrument.

It is to be remembered that when the signals within two blocks of the instrument are at danger, the switch instrument is at the clear position, that is, connected to the batteries. This indicates that a train may proceed from a siding to the main line without any danger of intercepting a through train. The series switch instruments J and S, it will be seen, open the home wire at both the east and westbound switches. This is the usual practice, and indicates danger to a train on either main line when either switch H or D is open, the connection for the other track line wires not being shown.

Signal section I is somewhat similar to the section O, with a number of extra connections. o and q are track relays connected respectively to the track batteries Z and F. The contacts c' are connected respectively to the signal boards M and R, the latter being also connected together, through the armature contacts a' and b'. z is in series with the signal battery and the distant line wire. It will be noted that all home signals are operated at the first block in the rear of the signal and all distant signals at the second block in the rear.

MUNICIPAL LIGHTING PLANT AT BLUFFTON, IND.

The following description of the electric lighting and power system owned and operated by the city of Bluffton, Ind., will afford an interesting study of the progressive inclination of many of the western cities.

Bluffton, the county seat of Wells County, Indiana, is situated about 25 miles south of Fort Wayne, Ind., on the Lake Erie and Western Railroad, and is in the midst of a rich agricultural, gas and oil-producing country. The city has a population of about 5000 people, has several miles of asphalt paved streets, elegant schools and public libraries, substantial brick and stone buildings throughout the business section.

A considerable number of the residence streets are provided with beautiful and costly dwellings, and the general appearance of the city is so pleasing in every way, due largely to the excellence with which the public affairs of the city are conducted, that its reputation and renown as the "Parlor City" of Indiana is well merited.

For many years Bluffton has owned its water works, consisting of two 1,000,000-gallon Holly compound pumping engines and a large cross-compound Ingersoll-Sergeant air compressor; and for several years past has operated in connection with the water works a series arc lighting plant for street lighting, consisting of two T. H. arc generators, driven by a 14 by 12 automatic engine.

Up to the winter of 1902-3 natural gas had existed in sufficient quantity to supply all local requirements for light and heat, but the supply of gas becoming gradually less, it was determined by the city in May, 1903, to build a modern plant to provide electricity for light and other purposes.

The power station, which includes the water works, is located in the eastern part of the city. The building is a handsome structure built of brick with slate roof and completely fireproof, divided into four sections; boiler room, pumping room, air compressor room and dynamo and engine room.

The engine room is 25 ft. high, 25 ft. wide and 36 ft. long, and is amply large for the machinery installed. The floor of the engine room is made of concrete and cement with a finished coat 2 ins. thick of granolithic marble, polished on the face. All foundations for engines, generators and exciters are built of concrete and cement.

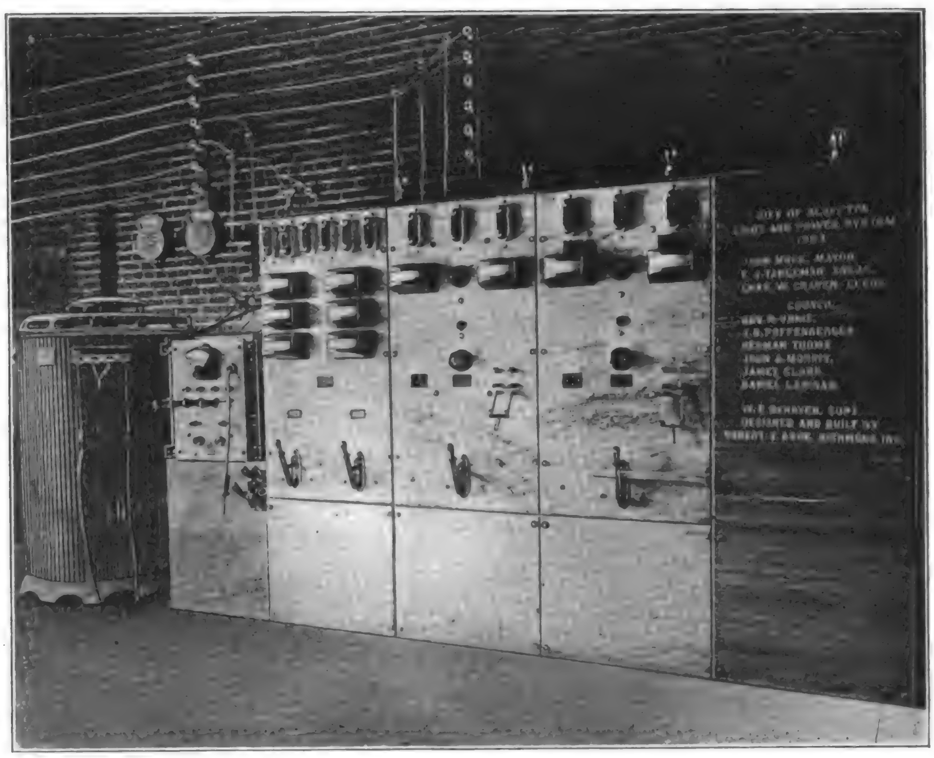

FIG. 1.—SWITCHBOARD IN THE BLUFFTON STATION.

The boiler equipment consists of four 125-h.p. boilers, built by the Bass Foundry and Machine Company, and arranged in two batteries.

The safe working pressure of these boilers is 120 lbs. Natural draft is supplied by two steel stacks 40 ins. in diameter and 100 ft. high, securely guyed by steel cables attached to posts well set in the ground.

The feed-water is passed through a heater made by the Steam Appliance Company, of Milwaukee, and is supplied with steam from the exhausts of the pumping machinery, air compressor and engines, the latter being by-passed to atmosphere through Burt exhaust heads.

Two Laidlaw-Dunn-Gordon duplex boiler feed-pumps are installed, each one being large enough to furnish all the feed-water required.

In the construction of the new electric

section of the power house, all of the old boiler headers and steam lines used in connection with the pumping machinery and old electric plant were removed and high-pressure flanged piping of the heaviest character was substituted in its place. The present steam header consists of a 14-in. pipe extending the full length of the boiler room. Each boiler is connected with a bend to the header, with a valve at each end of the bends. Connections for engines and pumping machinery is taken from the top of the header through easy bends and at all low points throughout the entire piping system, taps are installed for collecting the condensation and the water is returned through traps to the heater. Separators of the Milwaukee type are connected with suitable traps in all of the steam mains feeding the pumping and electric units. The complete piping work was installed by Woolen & Callon, of Indianapolis, Ind.

The electric lighting engines are of the vertical cross-compound type of unusual heavy construction throughout. The cylinder measurements of the large engine are 15 ins. and 26 ins. by 18 ins. stroke, and the smaller engine has cylinders 12 ins. and 20 ins. by 14 ins. stroke. These engines are of the direct-connected type, and were built by the Reeves Engine Company, of Trenton, N. J. The large engine has a normal capacity of 250 horse-power, and maximum of 476 horse-power; the smaller engine has a maximum capacity of 250 horse-power.

The engines are equipped with the Rites governor and a clever mechanical arrangement on the governor wheel whereby the pin supporting the governor is lubricated and shifted in its bearing with every action of the governor. The engines are also provided with adjustable steam-tight balanced piston valves, and the unusually compact form of construction together with the steam distribution employed has enabled a rather high degree of economy to be obtained in the operation of the engines.

Automatic oiling is employed throughout, no attention being required in this respect whatever beyond the filling of the oil reservoirs.

The generators are of the three-phase revolving-field type and develop 200 kilowatts and 100 kilowatts, respectively, the voltage being 2200 and the frequency 60 cycles. The speed of the large machine is 200 r.p.m., and of the small machine 257 r.p.m.

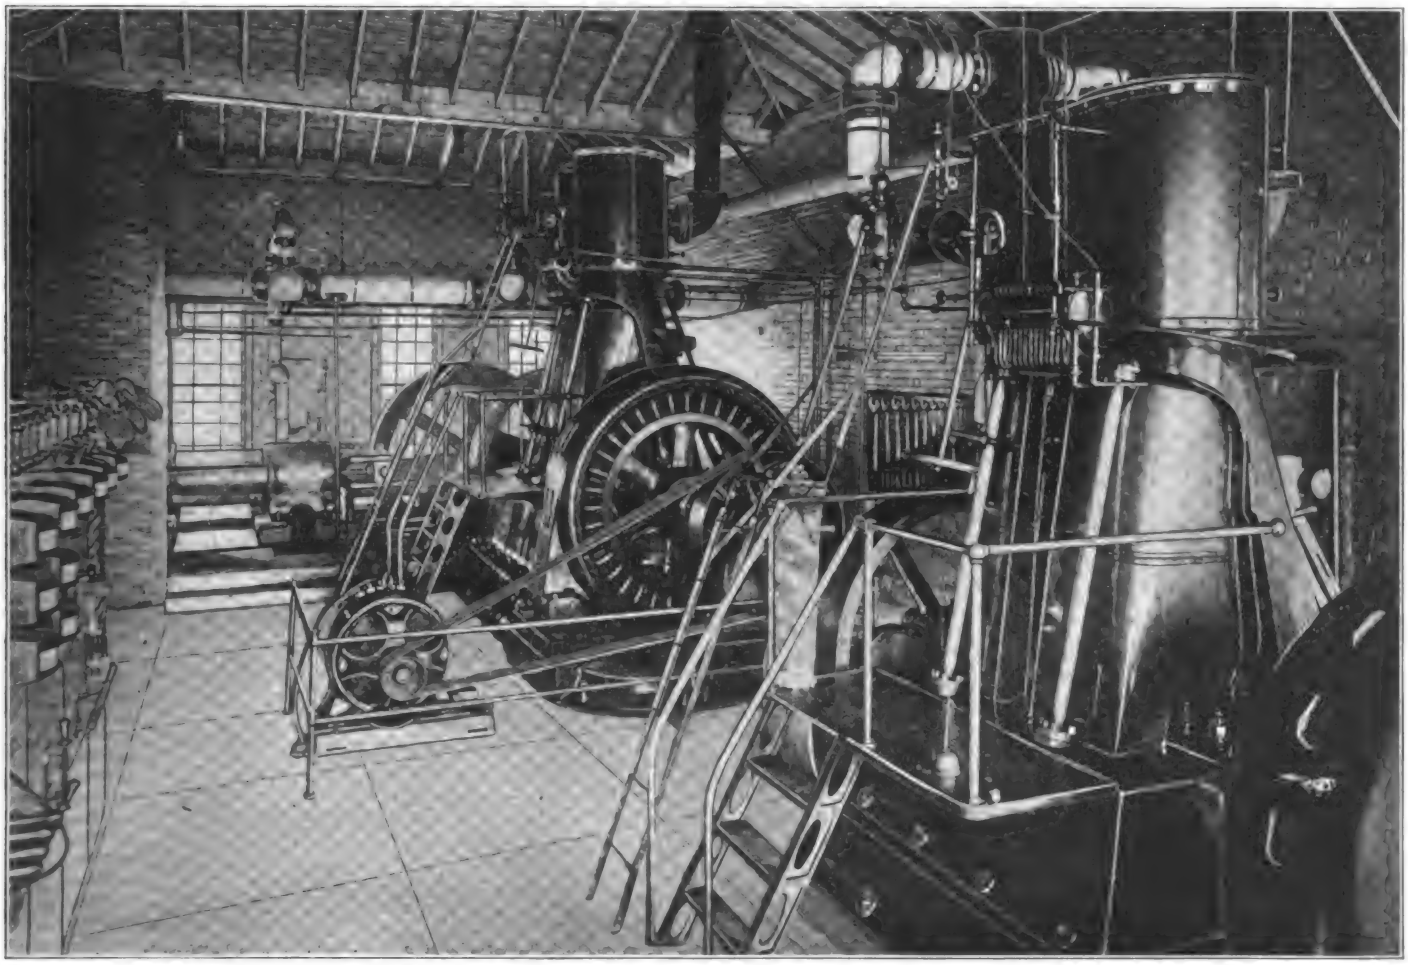

FIG. 2.—GENERATOR ROOM OF MUNICIPAL LIGHTING PLANT AT BLUFFTON, IND.

The exciters are two in number, each being driven by a belt from the end of the generator shaft. These exciters are of 11 kilowatts capacity each, and were made 50 per cent. larger than the requirements for excitation, so as to have a large factor of safety in this respect.

All lines from generators and exciters between the machines and switchboard are of rubber covered cables, drawn in American fibre conduits, waterproofed and concealed beneath the floor line. The switchboard is composed of four panels of blue Vermont marble 2 ins. thick by 30 ins. wide, and 90 ins. high, made by the General Electric Company, and completely equipped with its standard apparatus. Each of the generator phases has an ammeter of the dead beat horizontal type. Oil switches are used on all alternating-current circuits, and the usual equipment is provided for controlling the exciters. The board is also provided with voltmeters, synchronizing instruments and Thomson astatic ground detectors. On the rear of the board is installed, with floor supports, the generator field rheostats connected so as to be operated by insulated rubber handles on the front of the board.

Mounted on the brick wall in the rear of the switchboard are Thomson recording wattmeters, one connected in each of the generator circuits, which thus record the total output of each generator.

A 100-light series street lighting transformer is located in the engine room and supplies current for 80 G. E. enclosed arc lamps of the latest type. This portion of the equipment is controlled by an independent marble panel, of G. E. make.

The current for operating the street lighting service is taken from one of the phases, this phase being used exclusively for street lighting work.

All current is sold by meter, the price to the majority of customers being ten cents per kw.-hour. Wattmeters made by the Westinghouse Electric and Manufacturing Company are used. Transformers of various sizes are installed. These were provided by the Vindex Electric Company, of Aurora, Ill.

The city of Bluffton's plant began operation on March 24, 1903, and has continued in operation since, giving a day and night service with the best of satisfaction. At the time of starting the plant the connected load was 80 arc lamps and about 2500 incandescent lamps, and after six months of operation the incandescent load was more than doubled. All of the transmission lines from power house to centers of distribution are three-phase. Two of the phases being tapped at these points by single-phase lines, which feed into the transformers arranged with three-wire secondaries at 104 and 208 volts. All pole lines are substantially built of 30-ft., 35-ft. and 40-ft. poles, the location of all pole lines being in the alleys, no poles being allowed in the streets.

The design and construction of the entire work was entrusted to Robert S. Ashe, of Richmond, Ind.

DIRECT-CURRENT DISTANCE SWITCHES.

BY OUR BERLIN CORRESPONDENT.

Occasionally cases arise where it is desirable to switch in certain current consuming devices, such as, for instance, a group of lamps from a distance. The situation of the devices may be such that they cannot be seen from the switching place, so that a switch to be of best service should indicate whether or not the distant circuit has been completed. The device shown by Fig. 3 herewith fulfills these re-

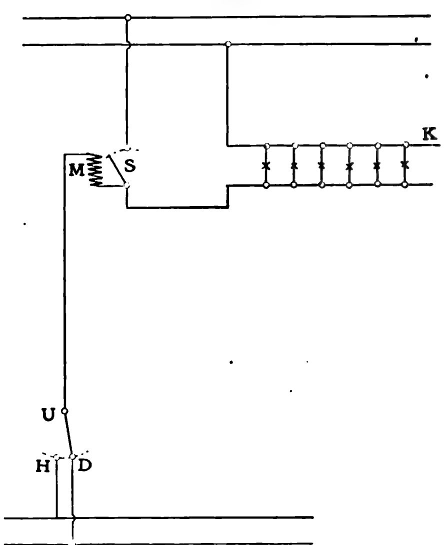

FIG. 1.

quirements in a very simple way, one small feeder being used exclusively, so that there is no occasion to resort to polarized armatures or other complicated elements.

The working of the apparatus may be made clear by reference to the diagrammatic sketches shown by Figs. 1 and 2; one being applicable to a two-wire system, and the other to the three-wire system. In the sketches, *K*, represents the distant current consuming devices that are to be placed in circuit, *S* is a lever serving to establish the connection with the circuit, the lever being under the influence of the electromagnet, *M*. One terminal of the magnet winding is connected to the distant circuit *K*, and the other terminal to the switch, *U*, at the switching place by means of the small feeder wire.

When it is desired to switch in the devices at *K*, the switch lever is placed on the contact, *H*. Current from the positive distribution bar will then pass through the coils of the electromagnet and the lamp to the negative pole of the distribution system, exciting the magnet, *M*, which in turn will cause the switch, *S*, to be closed. As soon

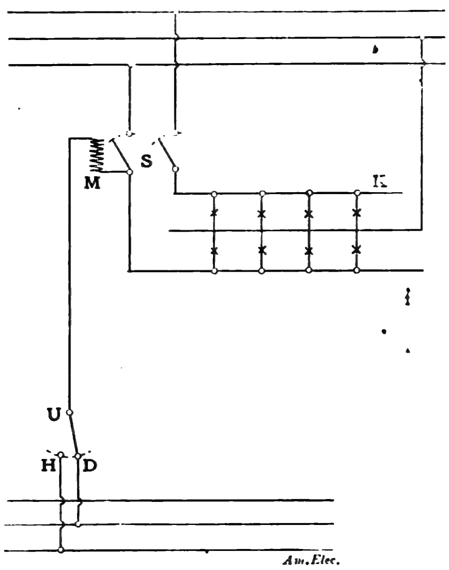

FIG. 2.

as the circuit at *K* is completed both terminals of the electromagnet are at the same

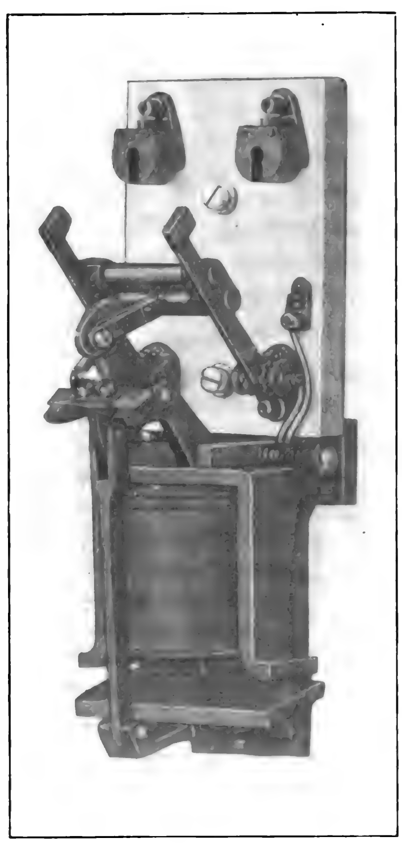

FIG. 3.—REMOTE-CONTROL SWITCH OPEN.

potential so that no current flows through the winding. In order to disconnect the devices at *K* from the circuit, the switch, *U*, is placed on the contact, *D*. The magnet winding will then be subject to the full potential of the distribution system, and the lever of the switch, *F*, is attracted into

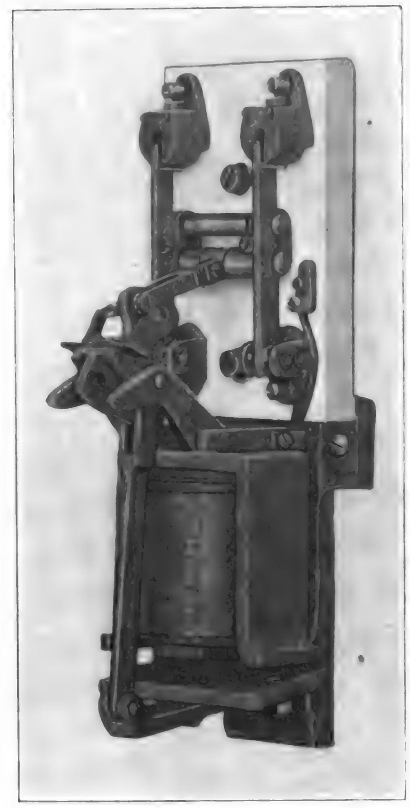

FIG. 4.—REMOTE-CONTROL SWITCH CLOSED.

the "disconnecting" position. Inasmuch as the magnet, *M*, is only subject to short

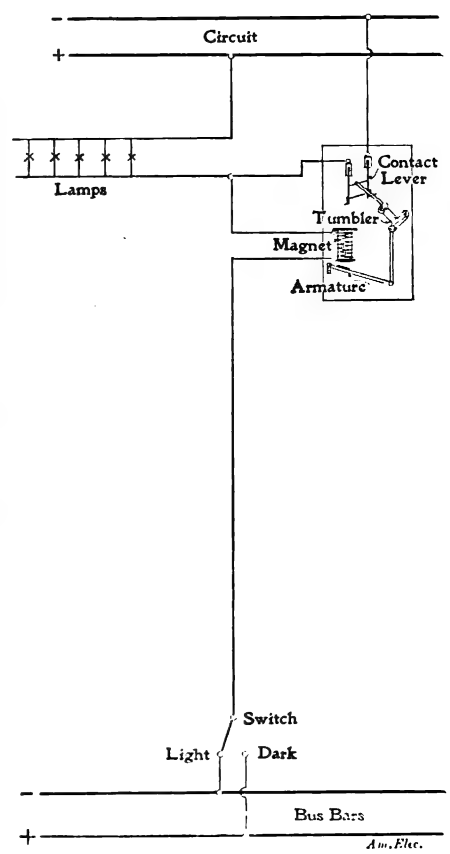

FIG. 5.—DIAGRAM OF CONNECTIONS.

current impulses the current consumption of the magnet is quite negligible.

The construction of the switch is clearly shown in the engravings which show the switch open and closed. The apparatus is

sufficient for a current intensity as high as 30 amperes, and is applicable to two and three-wire systems. The apparatus is enclosed in a cast-iron casing. When less

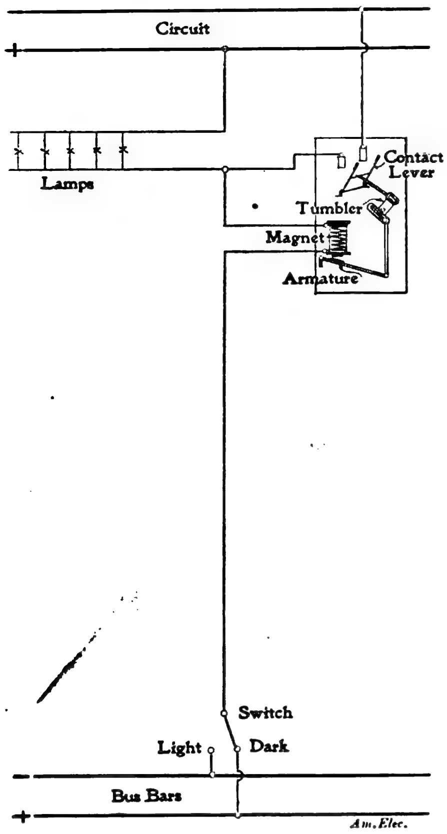

FIG. 6.—DIAGRAM OF CONNECTIONS WITH SWITCH OPEN.

than ten 16-c.p. lamps are in circuit, the reliability of the device is somewhat diminished by the lamp resistance being placed in the magnet coil, as the circuit is switched in. Ten instruments may readily be connected to a long distance wire having a cross-section of 5 sq. mm. and all operated from the one switch.

Electric Lighting of Passenger Trains by Storage Batteries.—The Pennsylvania Railroad is rapidly extending the use of electricity for lighting its passenger equipment by means of storage batteries, which are charged by the dynamos at the terminal stations. The system is proving very satisfactory. Some difficulties of a minor nature have been encountered and successfully overcome. The hard rubber battery cells, which were sometimes disturbed by the shocks to the cars in operation and temporarily disabled, are now placed in a lead-lined case. It shortly developed, however, that the lead lining was injured by electrolysis. It was found that at one of the charging stations there was a grounded wire which seemed to be responsible for the trouble; but there is liable to be more or less grounding at all the stations. In investigating the subject, the use of petrolite, a petroleum product, was suggested. The lead lining was dipped in this material, which formed a hard coating over the surface, and seems to have entirely obviated the difficulty.

Abstracts from Foreign Contemporaries

The Steam Turbine versus the Small High-Speed Engine.—The *Electrical Review*, of London, commenting editorially on the steam turbine and the small high-speed engine, says that "it is true that in the larger sizes of unit it (the turbine) has amply justified the claims of its supporters on the grounds of first cost, economy and simplicity, and this in spite of somewhat extravagant demands for additional power which has to be expended in the auxiliary plant. There seems, however, no immediate prospect of its being able to justify its supporters in the smaller sizes of unit, and it is this side of the question which deserves attention. * * * The general view held by those whose opinions deserve attention, fixes the limit at 500 kilowatts as the smallest size advisable—or permissible, so far as merits are concerned—for a turbine. * * * In the smaller sizes, turbine sets offer no inducement on the question of first cost, especially where allowance is made, as it should be, for the larger size of condenser required for giving the extra vacuum. On the question of simplicity and attendance in running, the performance of a good reciprocating engine of, say, 500 kilowatts, leaves little to be desired, and it is difficult to conceive of any other type of prime mover which will cost less, or be a source of less anxiety in the engine room. Finally, on the question of economy, the steam turbine has difficulty in approaching in these smaller sizes the economic results possible with the best forms of reciprocating engine, and this in spite of considerable additional power being expended in maintaining the most favorable conditions in the form of high vacua, conditions which are a charge of some weight on stations dealing with an average load factor, and which the reciprocating engine plant does not require. When this additional charge is taken into account, it leaves the small turbine sets considerably behind the reciprocating engine sets." Concerning the results of some steam consumption trials recently carried out by the Cork Electric Tramway Company on a 500-kw. vertical type turbine, the *Review* says: "It would, perhaps, scarcely be fair to compare the figures obtained in this isolated case with the numerous tests carried out on horizontal turbines, * * * * yet the figures are of interest in reminding us that the results obtainable with turbines of these smaller sizes are not what some would have us believe. At full load, with a steam pressure of approximately 150 lbs., with 100 degs. F. of superheat, and with a vacuum of 26.9 in., the steam consumption obtained at Cork was 20.6 lbs. per kw.-hour, and the best reliable results that have hitherto been obtained with horizontal turbines of the same size, and under somewhat similar conditions, can be put at about 19 lbs. of steam per kw-hour. * * * * Taking the results of some steam consumption tests obtained with reciprocating engines at Poplar for purposes of comparison with the results obtained at Cork—the output in both cases being similar—we find that the Willans engines at Poplar, with a somewhat higher steam pressure than prevailed at Cork (viz., 180 lbs. against 153 lbs.), but with a very much smaller degree of superheat (viz., 25 degs. F. against 104 degs. F. at Cork), and with a more usual vacuum (viz., 25 in. against 26.9 in. at Cork), gave a steam consumption of 18.64 and 19.52 lbs. of steam per kw.-hour—against 20.6 lbs. of steam per kw.-hour obtained at Cork. If the results usually promised for turbines in these smaller sizes were obtained with the same expenditure of power in condensing, one might be inclined to say there was little to choose between the two forms of prime mover, so far as economic performance was concerned. This, however, is not the case, and considerable additional power has to be expended to enable the turbines to give the results they do give. Hence it is that for sizes below 500 kilowatts, the advantage is in favor of the reciprocating engine, in spite of the greater cost of buildings, foundations etc., required for the latter. It would be unreasonable to argue—seeing what progress has been made in improving the steam turbine during recent years—that further improvements will not be brought about to justify the installaton of the smaller sizes, but, for the present, it is sufficient to say that the reciprocating engine, in the smaller sizes, still holds its ground."

Water-Cooled Rheostats.—A short time ago the *Engineer* contained a short description of a water-cooled iron wire rheostat used for dissipating electric energy during a dynamo test. It consisted of six lengths of iron wire, each .128 in. in diameter and 65 yards long, wound into coils and placed side by side in a wooden box with terminals at the ends of the coils connected up in parallel. This arrangement dealt with a current of 1660 amperes at 500 volts. About 27 gallons of cold water per minute were passed through the box. The test lasted five hours, and the wires showed no sign of deterioration. Each coil carried 276.17 amperes. The current density was 25,300 amperes per square inch. The theoretical drop in each coil was only about 247 volts, or, say, 50 per cent. of the actual drop. Admiring the compactness and cleanliness of the arrangement, but doubting the recorded drop, a correspondent of *The Electrical Times*, of London, had a small coil fitted into a box about 30 ins. long. The wire was of steel .0085 in. in diameter and 25 ft. long, wound into a coil 3/8 in. in diameter and 1-10 in. pitch. It was connected to the 220-volt service, and theoretically should have passed 10 amperes, but only 5 amperes would pass, and about half the length of wire had to be removed before 10 amperes would flow. The current density was 176,000 amperes per square inch, but the wire

carried it well. Clean tap water was used in the box to keep the wire cool. As the water does not act as a conductor no acid or salt is necessary. Subsequently two coils of this kind were used in parallel for testing a 75-kw. plant at 220 volts. The wire was of iron .0625 in. diameter. The box was 7 ft. long and 12 in. by 6 in. inside. There were four coils in the box, intended for testing two 75-kw. sets in parallel, but only one set was then tested, and only two coils were used. A small stream of tap water was passed through the box, but its volume was not measured. The temperature of the water rose only a very few degrees. The apparatus answered perfectly. The current density was 56,000 amperes per square inch. A very convenient arrangement is to put four coils in a box side by side with the terminals at one end provided with holes through which a horizontal copper bar can be passed and clamped. When the bar connects all four terminals in parallel the coils carry full load. When withdrawn from one terminal, three coils carry three-quarter load, two coils carry half load, and one coil carries quarter load. If switches be added, the load can be varied very quickly. A final adjustment of load within small limits can be made by varying the quantity of water passing through the box, for the resistance of the wire rises and falls as the temperature rises and falls, and the temperature depends upon the quantity of water passing through. The chief value of the device is in testing generating plants after they have been erected. Compared with a set of tubs, containing lead plates and salt water, replenished when the tubs boil over, by a jet of water from a hose pipe, directed by a man standing on an insulated platform, the contrivance is elegance itself.

Dublin Street Lighting System.—The arc light system of the city of Dublin, Ireland, is described in a recent issue of *Engineering* of London. In proportion to its area and population, Dublin, with its ad-

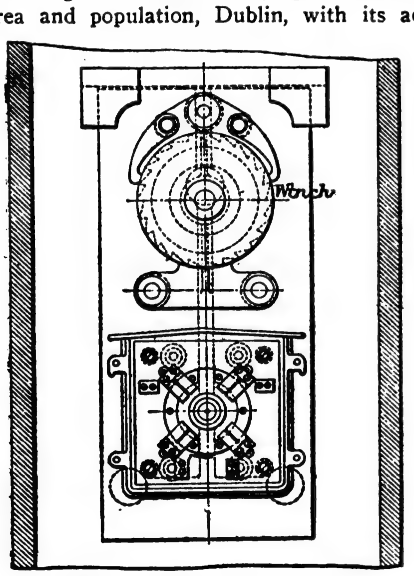

FIG. 1.—ARC LAMP WINCH.

joining townships, possesses a greater number of electric arc lamps than any other city in the United Kingdom. Electricity is generated in bulk at Pigeon House Fort, three miles from the city centre, and transmitted under a tension of 5000 volts, three-phase, to motor-generators in the city which convert it to 1100 volt, direct-cur-

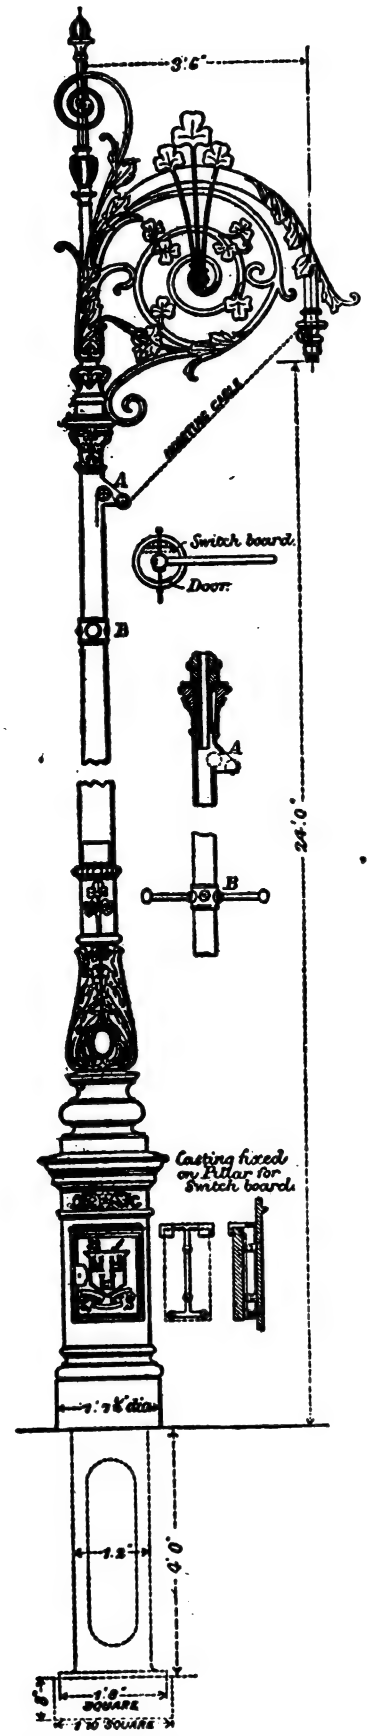

FIG. 2.—DETAILS OF DUBLIN ARC LAMP POST.

rent, for the arc circuits. From this station the arc light mains pass to five substations, where regulating resistances are provided. There are 23 circuits, having from 20 to 22 lamps per circuit, and it has been found necessary to adopt starting resistances upon the longer circuits in order to cut down the current at the moment of starting. Without the resistances, this current would be excessive, owing to the capacity of the cables. The posts (Fig. 2) have overhanging brackets, into which is worked the foliage of the shamrock. They weigh not less than 30 cwt. each, and the height to the arc is 20½ ft. The normal length below the surface is 4 ft. The base is bedded upon freshly-made concrete, and the hole is then filled and well rammed. The lamps are provided with lowering

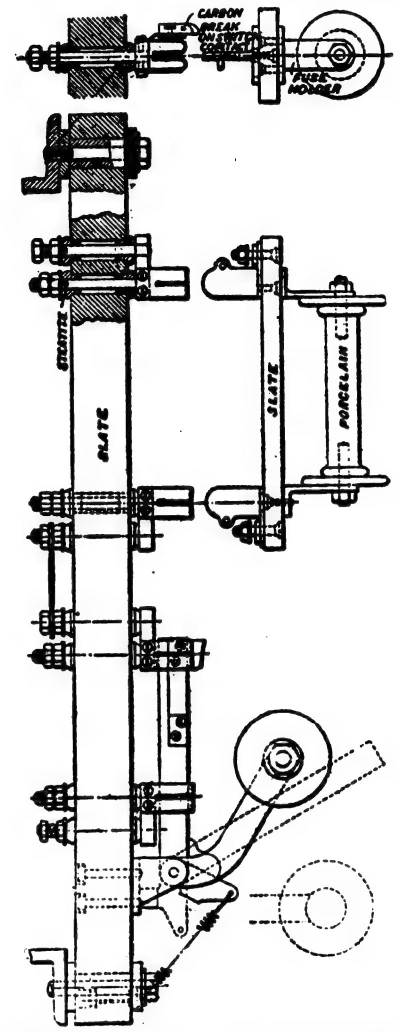

FIG. 3.—DETAILS OF SWITCH AND FUSE HOLDER.

gear, so that each lamp may be trimmed from the ground. The weight of the lamps is 65 lbs., and a flexible cable composed of six strands of ten wires each of 0.015 in. diameter is used for lowering and raising. This wire is built upon a hempen core well soaked in oil. The wire passes from the winch in the base of the pillar, up the stem and out at a point below the bracket between two 3-in. brass pulleys. These are so arranged that the inner pulley and the aperture through which the wire emerges are kept waterproof. The wire passes from this point across the under side of the bracket and enters the bracket tube over another pulley just above the nipple. The winches (Fig. 1) are provided with double pawls. When the point of one pawl is resting at the bottom of a tooth, the other is in the center of another tooth, and in this way

it is possible to use a fairly coarse pitch for the teeth while obtaining delicate adjustment. The handles are detachable, and are carried by the trimmers. When the spindle of the handle is thrust home, cams are opened, which raise the pawls; and similarly, when the handle is withdrawn, the pawls automatically bear upon the teeth of the winch. The possibility of the lamp's falling through carelessness is thus largely provided against. The rim of the wheel on the winch handle is of aluminum, and is

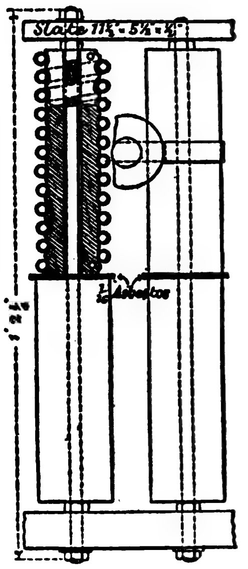

FIG. 4.—LINE RESISTANCE.

rounded and polished, being used by the trimmers as a hand-brake when lowering the lamps. In addition to the winch the base of the lamp contains an isolating switch (Fig. 3). This is mounted upon a china base, and has china contact carriers, the whole being contained in a weatherproof iron case. The switches are worked by steel keys encased in ebonite. The switch bridges over the lamp when it is desired for any reason to cut it out of circuit. No substitutional resistances are employed, and in practice it has been found that lamps burn equally well when two or even more lamps are cut out of a 20-lamp circuit. The line resistances for the lamps are shown in elevation by Fig. 4. The lamps themselves are of Verity's double-carbon type, constructed to burn 32 hours with 10 amperes. The cylinders are of corona and of copper, and the globes are opalescent, 20 ins. in diameter. Each circuit is fitted with double-pole fuses, with an automatic cut-out having carbon faces, as shown in Fig. 3. The specification regarding the burning of the lamps permits only a maximum potential difference of 3 per cent. across the terminals of any lamp. This means that each lamp on these long series must burn within 1½ volts up or down.

Counter-Current Jet Condenser.—In ordinary counter-current jet condensers of the vertical type the steam enters the condenser at the lower portion and rises upwards, whilst the condensing water enters the condenser at the top and falls downwards, thus insuring currents moving in opposite directions. It is, however, found to be inconvenient in some cases for the steam to enter the bottom of the condenser. The accompanying illustration, taken from the *Mechanical Engineer* of London, shows an arrangement by which the steam enters at the top or upper portion of the condenser and is then conveyed down a central tube of any convenient shape to the lower portion of the condenser, this tube being surrounded by trays for distributing the water which enters the upper portion of the condenser. By this arrangement, a counter-current effect is obtained in a jet condenser in which the steam and water both enter at the upper portion. The condenser is arranged in such a manner that the steam entering the upper portion of the condenser by the inner tube is partially condensed by admitting a spray of water at different points in the inner tube, whilst the remaining steam, after descending to near the bottom of the condenser, rises upwards in the condenser and outside the inner tube, and then meets the shower of condensing water falling from above. The condensation in the tube reduces the volume of steam passing through it and thus permits of a smaller tube than would be otherwise necessary. In the illustration *A* is the condenser casing, of cylindrical form. *E* is the inner tube, *C* the water inlet, *B* the outer and inner water distributing trays. The exhaust steam entering at the top of the inner tube *E* passes downwards and then rises around the outside of this tube; it

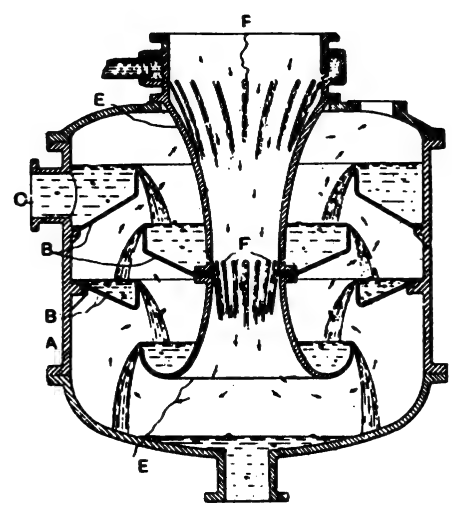

FIG. 5.—COUNTER-CURRENT JET CONDENSER.

then ascends through the condenser, coming into contact with several cascades or sheets of water; by this means the steam on emerging from the bottom of the inner tube flows in a complete counter-current direction to the condensing water, which entering the top tray overflows at the edge of this tray and then falls successively over the edges of the lower trays. The form and arrangement of these trays is such as will give a thorough mixing of the steam and water, and at the same time allow a free passage of air and vapor to the outlet to the dry air pump, which outlet is shown at the top of the condenser. The holes or slots, *F*, arranged in the inner tube allow a certain amount of condensing water to enter the tube and partially condense the steam during its passage through the tube.

Transformers in Series for High Tensions.—In a communication to the *Electritchestvo*, reprinted in the London *Electrical Engineer*, Mr. P. Kovalef makes a suggestion for obtaining high-tension current by a new method of employing several ordinary transformers. It is sometimes desirable to obtain a much higher voltage than that for which transformers at hand have been calculated. To that

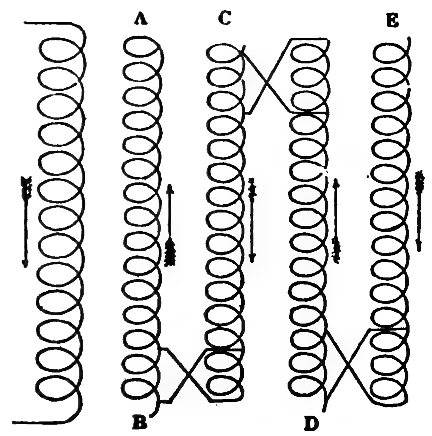

FIG. 6.—TRANSFORMERS IN SERIES.

end, Mr. Kovalef observes that the secondary wires of two or more transformers are generally connected in parallel with a source of low voltage, while the primary wires are connected in series. This manner of connecting, however, involves a high potential difference inside the separate transformers, between the high and low tension coils, and therefore it becomes a matter of risk to connect in series more than three transformers in order to obtain a voltage more than three times as high as the normal voltage of a transformer of a given type. The connection of transformers, illustrated in the accompanying diagram, gives a possibility of reaching much higher voltages. The low-tension winding of only one transformer is connected to the source of e.m.f., and the primary windings of the remaining transformers are left free, connections being established among the high-tension windings. Shunts are taken from these windings at equal distances from the end of each winding, say at one-sixth the total length. The manner of making these connections is shown in the illustration. The second transformer is fed by the first, the third by the second, and so on. It will be seen that, notwithstanding the number of transformers connected in circuit, the inside tension in each of them will not exceed the tension between the extreme points of the winding, while the total tension of the whole circuit will be equal to the geometrical sum of voltage of all the transformers, considering, of course, the tension between the points *B* and *C*, *C* and *D*, *D* and *E*, etc. The above method may also be modified by using the secondary wires of the transformer. Mr. Kovalef acknowledges, however, that the question of voltage obtainable often becomes more complicated owing to the self-induction of the transformers, and the total sum of voltages differs greatly from their algebraic sum.

"Bifluid" Tachometer. A simple and effective speed indicator called the "Bifluid" tachometer is described in the London *Mechanical Engineer.* One type of indicator is shown in the accompanying illustration. There are other instruments which can be mounted direct on any revolving part. The principle is easily explained. A revolving body which consists of a reservoir and an inner and outer tube contains two fluids of widely different specific gravity. The centrifugal force acts on the heavier fluid, pressing it outward and causing the light fluid to rise in the inner tube. Scales are fitted round the outer tube, which may be graduated to read revolutions per minute, miles per hour, feet per second, or knots per hour. The light fluid is red, and the scales are white, so that a very clear and distinct reading is possible. Up to four scales for different speed ranges can be fitted to one instrument, which allows of slight and rapid speed changes to be easily checked, and a large range of speed is thus provided for. An accuracy of ½ per cent is guaranteed by the makers. The instruments are suitable for fast or slow running machinery, and the scales can be graduated for speed ranges from 15 to 10,000 r.p.m. They are, according to the makers, absolutely reliable, the fluid rising and falling instantaneously at all speed changes with great precision.

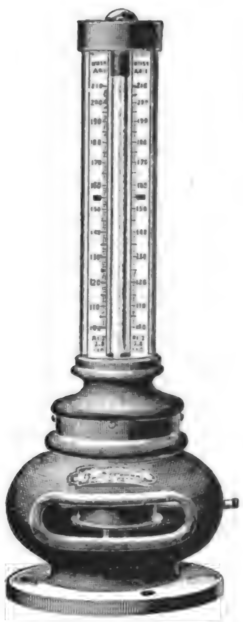

FIG. 7.—BIFLUID TACHOMETER.

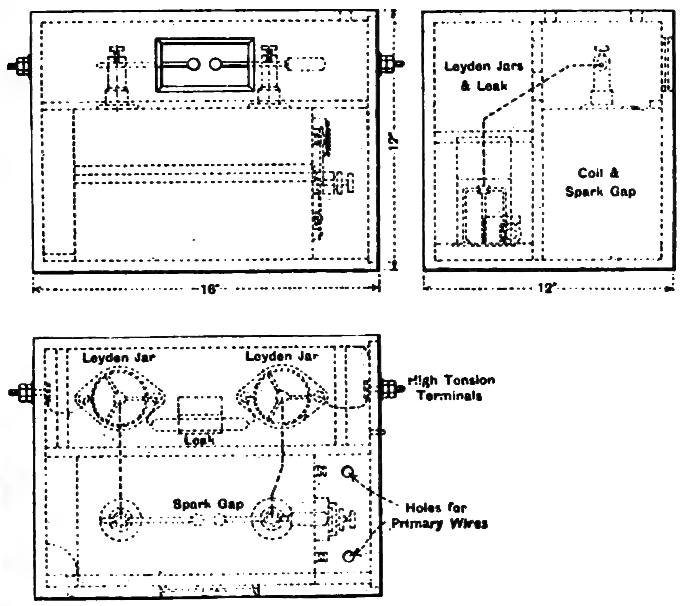

FIG. 8.—LODGE ELECTRIC IGNITER.

Lodge Electric Igniter for Gas Engines.—The London *Electrician* gives particulars of the Lodge igniter for gas engines, the chief claim for which is that the firing of the explosive charge is rendered quite positive and independent of leaks due to moisture or soot at the sparking plug. Fig. 8 shows the general arrangement of the apparatus, whose constituent parts are an induction coil, two Leyden jars, a leak and a spark-gap. The primary of the induction coil is fed from an 8-volt secondary battery, the current being given a pulsating character by a trembler or any other suitable device. It will be seen from the drawing that the secondary of the high-tension induction coil is connected up to the outer coatings of two Leyden jars, the inners of which are connected to the adjustable spark-gap. This spark-gap is an auxiliary device for producing well-defined disruptions, and must not be confused with the working spark-gap within the engine cylinder. The last-named spark-gap is connected directly to the two high-tension terminals of the induction coil, one of the connections being usually formed by the bed-plate of the engine. In order that the Leyden jars may be charged it is necessary to have some form of leak between the outside coatings of the jars. This leak must be of sufficient value to allow the jars to charge rapidly, and yet not diminish the volume of the spark in the cylinder by allowing the discharge current to pass through it. In the case of the gas-engine igniter a special form of liquid resistance is used, which offers a fairly good path to the charging current, but offers a large resistance to the oscillating discharge. The jars have a capacity of the order of 0.0001 microfarad.

Apparatus for Condensing Steam.—The London *Mechanical Engineer* describes some improvements in condensers for steam engines especially applicable to the type of condenser known as the "counter-current" and also applicable where separate pumps are used for taking the water and air from the condenser. The arrangement is illustrated herewith. The condenser, 1, is connected by a pipe, 2, to some known form of separator, 3, in which is placed a float, 4, so arranged as to open an air-valve, 5, thus admitting air into the pipe, 6, which leads to the air pump, 7. The operation takes place when a heavy flow of water comes over from the condenser, and by opening the valve, 5, the vacuum in the pipe, 6, is reduced for the time being, and the injection water resumes its normal intended direction of flow. The separator is provided with a pipe, 8, to take the separated water or fluid back into the condenser or into the pipe, 9, which leads to the water pump, 10. The flow of water into the condenser through the water supply pipe, 11, is controlled and adjusted in accordance with the level of the water in the condenser by the float, 12, acting on the auxiliary injection valve, 13, through the connecting rod and crank, 14, so as to open or close the latter as required, the level of the water being controlled by the water pump, 10. The float is also connected by the connecting rod and crank, 16, to the throttle valve, 15, or speed-varying mechanism for controlling the pump, and in its lower position or positions operates the valve, 15, for reducing the speed of the pump or pumps. The float is also connected by the rod and crank, 18, to an air valve, 17, leading into the pipe, 6, and when the float approaches its top position the valve is opened, thereby admitting air into the pipe for reducing or destroying the vacuum in the condenser, thereby checking the tendency of the water to rise and flow into the steam inlet pipe 19, which might occur if the water pump worked inefficiently, broke down, or from too large an injection of water.

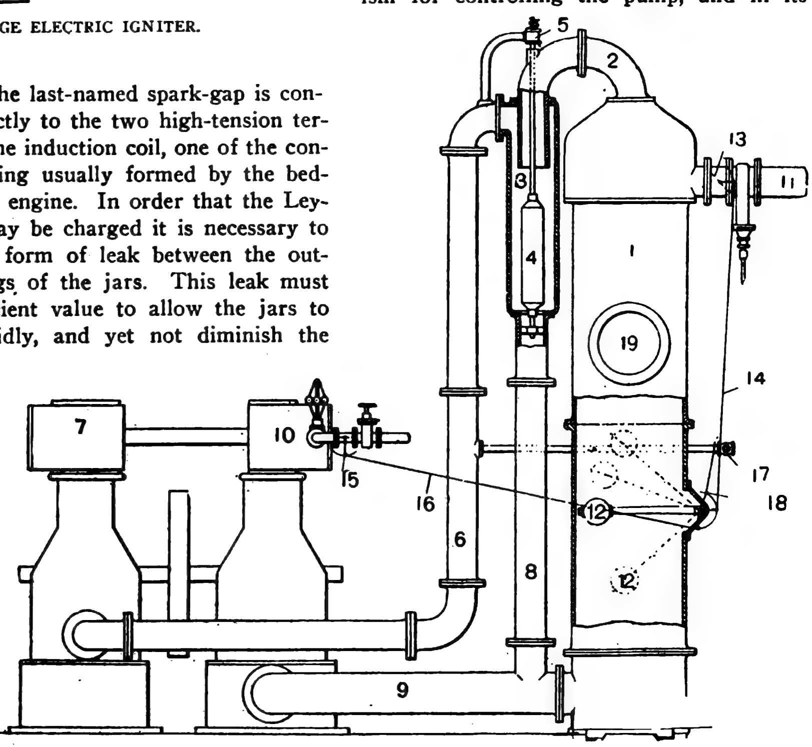

FIG. 9.—APPARATUS FOR CONDENSING STEAM.

Some Recent Electrical Patents

Dynamo Brush-Holder.—The acme of manufacturing simplicity, so far as brush-holders are concerned, appears to have been reached in the form patented by Mr. Fredrick M. Conlee, of Madison, Wis., and illus-

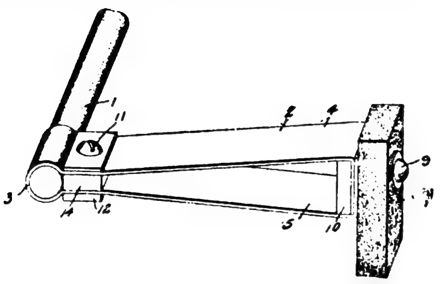

FIG. 1.—DYNAMO BRUSH HOLDER.

trated by Figs. 1 and 2 herewith. The brush-holder consists merely of a strap of spring metal, such as phosphor-bronze or spring brass, bent into the form shown by Fig. 2, together with small blocks, 10, 12 and 14, the functions of which are obvious. The loop, 3, is made to fit the brush-holder stud, as shown in Fig. 1, and is clamped to it by means of the screw, 11. The free ends of the strap lap each other, so that the holes, 6 and 7, match, and the screw, 9, which secures the carbon brush to the holder, passes through these two holes and is threaded into the block, 10, Fig. 1. The resiliency of the strap is relied upon to press the brush against the commutator and to allow it to yield to irregularities in the commutator surface. Patent 779,265.

Alternating-Current Railway System.—Fig. 3 illustrates diagrammatically the latest development in the alternating-current railway field, and is taken from a patent issued to Mr. J. H. Hallberg, of New York. The general scheme of the system comprises single-phase, alternating-current supply converted by means of a motor-generator into low-voltage polyphase alternating currents, which may also be of a lower frequency than the supply current, the polyphase currents being used to drive induction motors on the cars. The system is adapted to combined interurban and urban service, the cars for such combination service carrying a motor-generator set with its exciter. Cars for purely urban service, would require, of course, no motor-generator to operate on the system. Referring to the diagram, 5 is a single-phase alternator delivering current to a feeder, 6, to one side of which the rural trolley line, 8, is connected, and to the other side, the track, 10, of this part of the system. The high-potential, single-phase main, 6, is also available for the supply of lights and other single-phase apparatus. The city circuit is supplied from sub-stations, one of which is indicated diagrammatically at *X*. This station contains a motor-generator consisting of a single-phase synchronous motor, 22, and a polyphase generator, 26, belted to which is the direct-current exciter, *G*. For convenience in drawing, the members of the motor-generator set are shown with revolving-field magnets. The usual resistances are provided for regulating the field strengths of all three machines, and a storage battery, *H*, is provided for exciting the machines in case of an accident to the exciter, *G*. The polyphase generator of the motor-generator set delivers current through the mains, 12, to the three-phase conduit conductors of the city line, as shown at *B*. Each car intended to operate jointly on the city and country sections is provided with exactly the same equipment as the sub-station, except, of course, as to the size of the apparatus. In the drawing, *C* represents the synchronous motor of the motor-generator set, and *D*, the three-phase generator of that set. The car is provided with a double-throw switch, 57, which connects the three-phase motors, *F*, with either the polyphase generators, *D*, or the contact shoes, 17, 18 and 19, according to the section of road on which the car is operating. Obviously, it makes no difference so far as the railway is concerned what the frequency of the generator, 5, may be since the motor-generators, 22, 26, or *C*, *D*, can be wound to change the frequency to suit the railway requirements. The first claim of the patent is astonishingly broad in view of the state of the art; it covers a system of electrical distribution for railways comprising a source of single-phase current, means for converting it into polyphase currents, and polyphase motors on motor vehicles actuated by the polyphase currents. Patent 779,475.

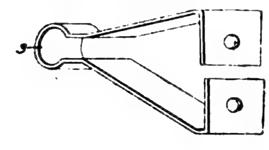

FIG. 2.

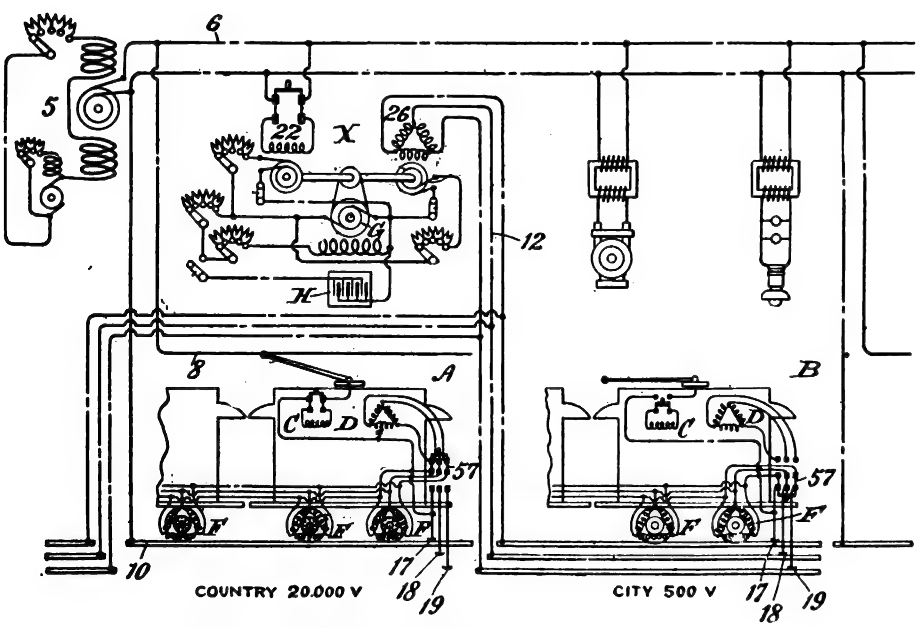

FIG. 3.—ALTERNATING-CURRENT RAILWAY SYSTEM.

NORTHWESTERN ELECTRICAL CONVENTION.

The Northwestern Electrical Association held its thirteenth annual convention at Milwaukee, January 18 and 19. An interesting paper on "The Successful Joint Utilization of Small Water Powers," was read by Mr. W. G. Jackson, of Madison, Wis., in which the author described how the Janesville Electric Company had gradually developed a system whereby all the power for supplying its entire service may be drawn from any one of three plants, and two of the plants are arranged so that the generators may be driven by either water or steam. Mr. O. M. Rau read a short paper on "Direct vs. Alternating-Current Distribution," in which he went over some familiar ground and also brought out the point that the use of turbine-driven alternators makes a 60-cycle rotary converter as stable as one of lower frequency and thereby removes the objection to the use of 60 cycles in a generating plant involving the application of rotary converters. He drew a comparison between direct-current distribution from rotary converter sub-stations and alternating-current distribution from transformer sub-stations, the generating plant being the same in both cases and the transformers being cut in and out of circuit according to load requirements just as the rotary converters would be. The figures deduced showed full-load losses of 21.4 per cent for the complete alternating-current system against 27.6 per cent for the mixed system; 17.2 per cent for the full alternating-current system at ¾ load against 23.4 per cent for the other; 13 per cent at half load for the

C. H. WILLIAMS,
President Northwestern Electrical Association.

full alternating-current system against 19.7 per cent for the mixed, and 8 per cent for the full-alternating-current system at ¼ load against 17.1 per cent for the mixed system. His comparison of the first cost of plants of the types described, based on a station having 15,000 kilowatts full-load output capacity, showed a saving on the first cost of apparatus and buildings for sub-stations alone of $130,000. It was not stated what percentage of the total cost this is. The paper was based on an investigation of the conditions in the city of Racine, and as a result of the investigation the lighting distribution system there was changed from direct-current three wire to single-phase alternating-curent at 60 cycles.

In a paper on "The Rating of Street Lights," Prof. George D. Shepardson urged the making of contracts with municipalities in such manner that both parties to the contract will know exactly what is required and either party can determine accurately whether or not the contract is being carried out. He advocated lighting contracts based on the kilowatts supplied. Mr. C. H. Williams read a paper on "Distribution and Dollars," in which he analyzed the question of the most profitable incandescent lamp efficiency, the cost of lamp renewals, losses in transformers, and other factors affecting the cost of distribution. In a paper on "Series Alternating Arc Lighting," Mr. E. P. Warner appeared as a staunch advocate of this class of service and eulogized almost everything involved in a system of this sort. He brought out the important fact that as a rule arc lamps are not sufficiently insulated from their supports and that a lamp should be treated as though all of its exposed parts were alive. "The Single-Phase Railway and its Possibilities," was the title of a paper by Mr. Clarence Renshaw, of Pittsburg, who held up to view all of the well-known limitations of the present direct-current railway system and to describe at length the Lamme single-phase series railway motor, which was apparently considered a panacea for all the ills of railway car equipment. Mr. J. W. Shuster, of the University of Wisconsin, read a paper in which he emphasized the well-known desirability of working up a day motor load in central stations.

At the election of officers for the ensuing year, Mr. C. H. Wiliams, of Madison, Wis., was elected president; Mr. Roger N. Kimball, of Kenosha, Wis., first vice-president; Mr. Harold Almert, of Oak Park, Ill., second vice-president, and Mr. William R. Mercein, of Milwaukee, secretary and treasurer. The board of directors consists of Messrs. P. H. Korst, of Janesville, Wis.; Ernest Gonzenbach, of Sheboygan, Wis., and H. J. Gille, of St. Paul, Minn.

CENTRAL STATION ENGINEERS.

IV.

Ernest H. Davis.

Ernest H. Davis was born in Philadelphia, Pa., on November 13, 1859. He was educated in the public schools of his native city and afterwards took up the study of law, being admitted to practice at the bar in 1882. He followed his profession for a while; but having inclinations for industrial and transportation enterprises, he gave up his practice to enter the steam railroad field, eventually becoming president of the Brooklyn, Bath and Went End Railroad Company, of Brooklyn, N. Y., which company

ERNEST H. DAVIS.

is now a part of the Brooklyn Rapid Transit. About the year 1894 he became interested in the Lycoming Electric Company, the Williamsport Passenger Railroad Company and other street railway companies of Williamsport, Pa. He also became associated with the Edison Electric Illuminating Company later, and is still connected with the active management of these various enterprises. In 1903, Mr. Davis was elected president of the Pennsylvania Street Railway Association. For the past few years Mr. Davis filled with remarkable success and efficiency the office of secretary of the National Electric Light Association, and at the convention of the association held in Boston last May, Mr. Davis was elected president of that organization.

An Uninterrupted Run of a year's duration is credited to a Parsons steam turbine built by the Swiss firm of Brown, Boveri & Co.

AN INDEPENDENT TELEPHONE ASSOCIATION FOR TEXAS.

At a meeting of owners of independent telephone exchanges, held in Dallas, Tex., recently, there was inaugurated a state association of independent telephone companies. At this meeting, which was the outcome of some able missionary work by Mr. A. A. Miller, manager of the North Electric Company's Dallas office, Mr. E. W. Dunaway, general manager of the Paris telephone exchange, was elected temporary chairman, and Mr. J. B. Earle, secretary of the Texas Telephone Company and general manager of the Brazos Valley Telephone Company, of Waco, was elected temporary secretary. The organization of the new association was perfected with an absence of friction and unanimity of sentiment which augurs well for the future of the body.

NOTES.

The United Engineering Building.—The consulting engineers for the construction of the United Engineering Building to be erected under the Carnegie gift were appointed at a recent meeting of the Conference Committee. Mr. C. O. Mailloux was selected for the consulting electrical engineer, and Mr. Alfred R. Wolff as consulting engineer for heating and ventilation on behalf of both the United Engineering Building and the Engineers' Club. The firm of Bates & Neilson were selected as consulting engineers to look after the interests of the Engineers' Club.

A Point for Wireless Telegraphy.—The peculiar value of wireless telegraphy in marine work was demonstrated on January 3, when the steamer "Pilgrim," of the Fall River Line, collided with a schooner between Newport and Fall River. A thick fog was prevailing at the time, and the steamer struck the sailing vessel a glancing blow on one side. Fortunately no damage was done to the schooner below the water line, but this was not known at the moment, and the "Pilgrim" immediately summoned help by a wireless telegram to the torpedo station at Newport and stood by until the tug sent out from the station arrived.

Industrial Opportunities in Italy.—In a recent United States Consular Report reference is made to the improvement of water powers in Italy by means of which there will be available in the city of Venice about 10,000 electrical horse-power. This, it is stated, will open a good market for electri-

cal machinery, fixtures and supplies, but the Consul expresses the opinion that catalogues are of no service in making sales; this can only be done by a salesman canvassing the district. It is stated that the electrical apparatus and supplies manufactured in the United States could easily predominate in the Italian market if the opportunity were promptly embraced by American manufacturers.

Boston's Evening Polytechnic School.—The Young Men's Christian Association, of Boston, Mass., in its Department of Applied Electricity, has inaugurated an evening polytechnic school of unusual merit. The Department of Applied Electricity is in charge of Prof. William L. Puffer, of the Massachusetts Institute of Technology, and the Advisory Board includes members of the staffs of the Edison Electric Illuminating Company and the Boston Elevated Railway Company. The first term of this school opened January 10. The work of the present year will consist of a lecture course of eight weeks, the lectures being delivered on Tuesday and Thursday evenings, a recitation on each Friday evening, and a laboratory course which will open at the conclusion of the lecture course.

National Electric Light Association.—Mr. Henry L. Doherty, chairman of the Committee on Membership of the National Electric Light Association, is doing some vigorous work in the direction of increasing the membership. Small pamphlets have been prepared, containing extracts from the constitution relating to membership and a blank to be signed by an applicant for membership. These have been sent judiciously to companies and persons eligible for membership under the different classes, together with circular letters calling attention to the booklet and to the advantages of membership. The booklet is attractively prepared and the arguments are convincing. Mr. Doherty's campaign bids fair to produce an enormous increase in the class of individual membership and should also augment the company membership very considerably.

Increasing Furnace Efficiency.—According to the claims made by Cyrus Prosch, of Coatesville, N. J., he has devised a method of greatly increasing the efficiency of the ordinary boiler furnace without a proportionate increase in operating expense. Broadly stated, his method consists of delivering into the furnace, above the fire, intermittent jets or streams of air in addition to that taken into the furnace from below, by draft, in the usual way. The idea of introducing air above the fire is not new, but Mr. Prosch's method of admitting the supplementary air intermittently is claimed to give results far and away superior to those obtained by continuous admission. The improvement obtained, he states, depends not only on the quantity of air admitted, but on the frequency of the admissions and their duration. We do not vouch for the soundness of Mr. Prosch's claims, but he himself is undoubtedly convinced of the efficacy of his method and makes the claims in all sincerity.

Institute Annual Dinner.—The annual dinner of the American Institute of Electrical Engineers will be given in the ballroom of the Waldorf-Astoria, New York City, on February 8, and promises to be a most interesting occasion. In view of the recent opening of the Subway, thus adding underground traction to the domain of electricity in America, the adoption of electric locomotives by the New York Central and Pennsylvania Railroads for their great Manhattan terminal divisions, the equipment of the Long Island Railroad with electricity, and other signal events, the Institute has decided to devote this dinner to emphasizing the triumph of electric traction. A number of men prominent in this field will be present, and some novel features will be introduced. As is usual on these occasions, ladies will be present. The participation of the ladies was a feature that elicited Mr. Carnegie's enthusiastic commendation at the famous Institute Library dinner, at which he made his gift of $1,000,000 for the United Engineering Building. Over 400 were seated at the Edison dinner last year, and the attendance in February promises to be equally large.

Proposed Investigation of New York's Lighting and Railway Service.—The Committee on Gas and Electricity, of the Merchants' Association of New York, has presented to the Legislature a memorial asking the passage of a resolution authorizing the appointment of a legislative committee empowered to examine into, report upon and make recommendations concerning the conditions surrounding the production, distribution and cost of gas and electric light in the city of New York and of the operation and control of electrical subways in this city. The object of the resolution is to determine the reasonableness of the charges for gas and electric light service and to investigate the city's equity in the accounts and earnings of the subways. The memorial appears to be chiefly an agitation of the question of municipal ownership. It contains the statement that while Manhattan Borough pays $146 per annum for each arc lamp of 2000 nominal candle-power, the prices charged by various electric light companies in "sixty-eight other cities where conditions similar to those in New York exist" average $88.60, for the same size of arc. Irrespective of the merits of the gas and electric light companies' side of the question, the argument presented in the memorial is conspicuously unsound for the reason that there are not sixty-eight other cities in the entire world where conditions similar to those in New York exist.

The Coming Electric Light Convention.—Nothing is being left undone in planning for the convention of the National Electric Light Association to be held in Denver and Colorado Springs the week of June 6, and the committees in charge of the preparatory work will continue their labors vigorously from now until the time of the meeting. A great many members have written to the secretary and members of the committees, assuring their attendance and the attendance of many others. This has encouraged those engaged in making preparations, and they are now planning for the entertainment of several thousand visitors. The committee on advertising has reversed the usual conditions. Instead of depending upon the railroads for all of the advertising, this committee is putting out its own matter, and in such a way that the publicity will be of the highest class possible under the circumstances. A considerable quantity of the matter that is going out, however, is being supplied by the railroads, but it is much more expensive than usual. As an illustration of this is cited the sending out of the souvenir cards regularly sold by stationers and others. These go to all parts of the country and show scenic points that will be shown to the visitors. Booklets are being sent to members and others containing detailed information regarding the hotels of almost the entire state, from which the recipient can determine the exact cost of his stay in the several points he may visit; the information is all official, from the hotel men themselves. Another booklet contains detailed information regarding side trips and scenic points.

Operating Cost of Electric Elevators.—We reprint the following data upon the cost of operating electric elevators appearing in a recent circular of the Cincinnati Gas and Electric Company. While the cost varies greatly with the type, and the extent to which the elevator is used, the following figures, we think, give a fair average for the guidance of prospective users of electric elevators:

SIX MONTHS' AVERAGE.

No.	H.P.	*Freight Elevators* Average Monthly Cost.	No.	H.P.	*Passenger Elevators* Average Monthly Cost.
1	10	$11.92	1	15	$39.54
1	10	10.00	2	20½	19.05
5	20	33.01	1	18	65.83
1	5	5.00	2	17½	17.30
1	5	4,00	2	22½	23.57
1	5	5.00	1	15	14.22
1	5	4.00	5	73	59.40
1	5	7.37	2	32	38.16
1	5	4.00	3	38½	34.55
1	5	11.86	2	10½	19.80
1	10	9.50	1	8	9.73
1	10	9.50	1	8	14.87
1	8½	9.49	1	11	18.42
2	25	23.75	1	15	9.15
1	5	3.50	1	15	22.01
1	10	9.50	1	15	4.75
1	5	4.75	2	16½	17.62
1	10	11.30	1	12½	14.66
1	8	7.60	2	12½	12.33
1	20	28.06	2	11	17.74
1	7½	7.12	3	41	37.95
1	5	4.75	1	10	23.49
1	5	4.60	1	16	18.24
1	5	5.25	1	10	19.05
1	7½	7.12	1	10	19.50
			1	13	13.30
30	221½	$241.95	1	10	18.98
			1	26	35.31
			45	523	$658.58

Average cost per elevator per month, $8.
Average cost per month per horse-power, $1.09.

Average cost per elevator per month, $14.64.
Average cost per month per horse-power, $1.26.

The average monthly cost for a freight elevator is $8.00 and for passenger elevators $14.64. It will be evident that these figures cannot be duplicated in a steam or hydraulic equipment.—N. Y. Edison *Bulletin*.

Address all business communications to AMERICAN ELECTRICIAN, *114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, draft, express or postal money order, payable to McGraw Publishing Company.

Entered in the Post Office at New York as second class mail matter.

Vol. XVII. FEBRUARY, 1905. No. 2

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue, 18,000 copies are printed. The total number of copies printed so far this year is 38,000, or an average of 19,000 per issue.*

CONTENTS.

Electric Hoists in Building Construction.

It seems odd, in view of the "state of the art" of electrical engineering, that the out-of-date donkey-engine hoist should still be used in any city of respectable size for handling material in the erection of buildings. Electrically-driven hoists have long been available; they require no licensed engineer, are more easily portable, more economical in operation, more flexible in control, and entail an immensely lower fire risk than the steam hoisting engine, not to mention the absence of fuel supply, noise, smoke and ashes. Fuel economy does not affect the problem greatly, since the cost of the fuel used by the most wasteful hoisting engine is a bagatelle in the total cost of the building. But the vastly greater convenience of application, reduced fire risk and lack of necessity for a skilled attendant are of ample importance to justify the use of motor-driven hoists to the extinction of the antiquated mechanism so generally used now.

Motor-Driven Machine Tools.

That the driving of machine tools by electric motors is no fad but a permanent development will not be questioned by any thinking engineer. The many advantages of electric drive are now obvious; leaving aside all others, the better arrangement of the tools, the facility of control and the capacity for momentary overloads have established motor drive securely. Having reached this stage of development, it behooves all machine tool builders to face squarely the fact that the best results from a motor-driven tool can be obtained only when the tool has been designed from the start with a view to motor drive. It is entirely practicable to "hitch up" a motor to an existing machine tool or other piece of similar machinery, and the article by Mr. Hanchett, which we print elsewhere in this issue, indicates methods of doing this which will be found most useful to all who are confronted with the problem. It is undeniably true, however, that this procedure is a makeshift and therefore cannot endure; the proper method is to build the machine specifically for motor drive, with proper accommodation for the motor and appropriate means of power transmission from the motor shaft to the main shaft of the driven machine.

The foregoing refers, of course, only to individually-driven machines, but, although individual drive appears to be extravagant in the case of tools requiring less than two or three horse-power, the tendency is strongly toward equipping every machine with its own motor, down to the smallest commercial size of motor. If tools are designed especially for individual motor drive, the discrepancy between the costs of singly-driven and group-driven machines will be much less than it is now. There seems to be a magnificent opportunity just here for tool builders and motor builders to "get together" and perfect a joint policy that will enable them to produce a combined tool and motor which will not be prohibitively expensive in comparison with the same tool belt-driven in a group by part of the power from a larger motor. With the number of variable-speed motors on the market, there should be no difficulty in carrying out such a policy without involving unpleasant commercial tangles or restrictions.

Fire Risks in Isolated Plants.

The correct design of a modern isolated plant involves the solution of so many problems and the consideration of so many diverse questions that the matter of fire risk in the plant equipment often receives little if any attention beyond that given to the building or establishment as a whole. Then again, it is frequently the case that by the time the necessary and "extra" expenditures for the plant have been met or provided for, no money is available for the installation of automatic alarms, sprinkler systems, etc. Fortunately, the majority of isolated plants do not in themselves constitute serious fire hazards. If designed properly and installed according to the design, the danger of overheating neighboring inflammables from smoke flues, chimneys, ash piles, etc., is very small. The fire risk from electric wiring and switches is practically *nil* where vigilant insurance inspectors are detailed.

Even in the best-designed isolated plants, however, there is always *some* fire risk, and this can be reduced to a negligible quantity by inexpensive precautions and prudent operation. Thermostat alarms should be installed at all points near sources of possible conflagration and also at different points, symmetrically located, throughout the establishment. In the way of simple but practical means for fighting fires in their incipiency, several pails of sand, with small scoops for proper distribution, two or three asbestos blankets three or four feet square, and a moderate number

of approved fire extinguishers will go far toward minimizing the risk from fires after they start. In the way of guarding against the starting of fires, the disposal of greasy waste in a metal receptacle having a self-closing cover, the daily cleaning of floors and closets, the keeping away from incandescent lamps or other heat sources of inflammable substances such as paper, cloth, excelsior, etc., the intelligent use of lamp cord in the vicinity of pipes and other metal structures, the storage of gasoline out of doors and the abolition of matches are all such simple and obvious precautions that one would think it unnecessary even to suggest them; nevertheless, there are hundreds of plants in which most if not all of these are either indifferently observed or neglected entirely.

An excellent plan for insuring attention to precautionary measures of the character just indicated is to work out a system of report blanks which will show the condition of the plant with respect to fire hazard, and have these blanks filled out by the chief engineer at stated intervals—say weekly. One blank should show the quantity of water in the storage tank, and the actual condition, in detail, of the fire pumps; the number of fire extinguishers, the number and condition of thermostats or other alarm apparatus, the condition of valves affecting the fighting of fire, the accumulation of inflammable or heat-producing débris and other information affecting the fire risk, in the fullest detail. Such a blank can easily be worked out to fit any plant, from the smallest to the largest, and it should be filled out with the greatest care, accuracy and regularity.

A Farcical Investigation.

The Comptroller of the City of New York is prosecuting an alleged investigation of the cost of street lighting by municipal plants, the ostensible object of the "investigation" being to determine whether or not New York could probably operate its own plant more economically than it can buy service from the local companies. From the character of the information disclosed, the bullying attitude of the "investigators" toward citizens who attempt to find out what it all means, and the evident determination to rush into municipal ownership whether or no, it would seem that peanut politics has much more to do with the Comptroller's feverish antics than virtuous solicitude for the proper disbursement of the taxpayers' money. Thus far not a single completely accurate statement concerning the cost of municipal lighting in cities afflicted with such plants has been brought out, so far as the published accounts of the "investigation" go.

Time-Saving Tables.

Any means of reducing the time required in making even the simplest computations, as well as saving one's mental wear and tear, is usually met with a warm welcome, and we trust that the set of scales and the table printed on pages 93 and 94 will be found of sufficient merit to be classed as "means" of the kind mentioned. The results obtainable with the scales, while seldom absolutely accurate, will in almost every case be found as nearly accurate as it is possible to obtain without radically altering the depth of the magnet winding and going through the elaborate work of redesigning the winding throughout. The table of mean lengths per turn of wire should be of general value, since it is based on a clearance between the magnet core and the bore of the coil which, without being excessive, is ample for any ordinary bobbin material or insulation. As stated in the explanatory text accompanying the table, the mean length per turn of wire in a magnet coil is a determining factor in the lay-out of a winding for a stated potential at its terminals; it is also important in dealing with coils built for stated currents, since the resistance of the coil must be ascertained in order to know what voltage will be required and what the loss in watts will be. The relation of watts to coil surface is another important factor in magnet windings. It is expected that a table of coil circumferences, on a plan similar to that of the table of mean lengths, will be ready in time for publication next month. This will be of service, of course, in readily ascertaining the coil surface per unit of length parallel to the core.

The Telephone in Isolated Plants.

The use of the telephone in the engineer's department of an isolated plant, though not a matter of vital importance in many cases, is well worth consideration by owners of such plants. Most establishments operating their own lighting and power plants are equipped with a local system of communication between different departments—usually an interior telephone system—but this is of no service for communication with the outside world by the chief engineer of the plant. Whenever it becomes necessary for him to employ the city exchange service, he usually has to leave his department and use a general telephone instrument, which may be in such demand as to cause appreciable loss of time and money by delay. Upon investigation, it will usually be found that the chief engineer of an isolated plant has many occasions per week to use city exchange service, and in almost every case his telephonic conversation has reference to matters of record in his department, which record could not be consulted while using a remote telephone instrument. Again, in case of an accident causing personal injuries, the availability of a telephone right in the engineer's quarters might easily be worth many times the annual cost of the service. In establishments having branch exchanges connected with the city exchange, failure to put an extension instrument in the chief engineer's department is short-sighted to the last degree.

Communications for Publication.

Readers interested in our department of Letters on Practical Subjects—and we cannot imagine any who are not so interested—will find at the head of that department a notice to the effect that letters for publication in a given issue of the paper must be in this office not later than the 15th day of the month preceding that issue. This rule has not been adopted from mere arbitrariness; it is strictly necessary in order that the printing of the large number of copies issued each month may be finished in time to mail the copies on the last day of the month. The paper cannot be printed all at once; it has to go to press in sections and the section containing the letters department is necessarily closed early in the month—hence the rule to which we are calling attention. Although this rule has been printed at the head of the department for the past six months, we receive between the 17th and 25th of every month letters intended for publication in the next issue, and which we ourselves very much desire to print; most of these are unavailable for use in future issues. We earnestly request our readers, therefore, to keep in mind our mechanical restrictions and favor us with their communications early enough for them to be used in season. We also invite any and all readers to contribute to this department—to "tell their troubles" to the other readers freely and look to each other for assistance and helpful suggestions.

DESIGN AND CONSTRUCTION OF SMALL DYNAMOS AND MOTORS.

BY CECIL P. POOLE.

Mechanical Details.

As in laying out the electrical and magnetic proportions of a machine, the working out of mechanical details of construction is best begun with the armature. In the multipolar machines covered by these articles, it is intended that the armature discs shall be clamped together by means of two end-plates and four bolts passing through holes in the core and the end plates. The plates are to have flanges, as indicated in Fig. 15. In the bipolar machines, these flanges and the ventilating holes are omitted, leaving the end-plates simple discs, which are clamped by two nuts on the shaft. The dimensions of the end-plates are given in Table XII. Table XIII gives constants by means of which the diameter of the central hole in the armature core may be determined. Subtracting the value of K_0 from the diameter of the tooth-root circle gives the maximum allowable diameter of the central hole in the armature core discs and end-plates.

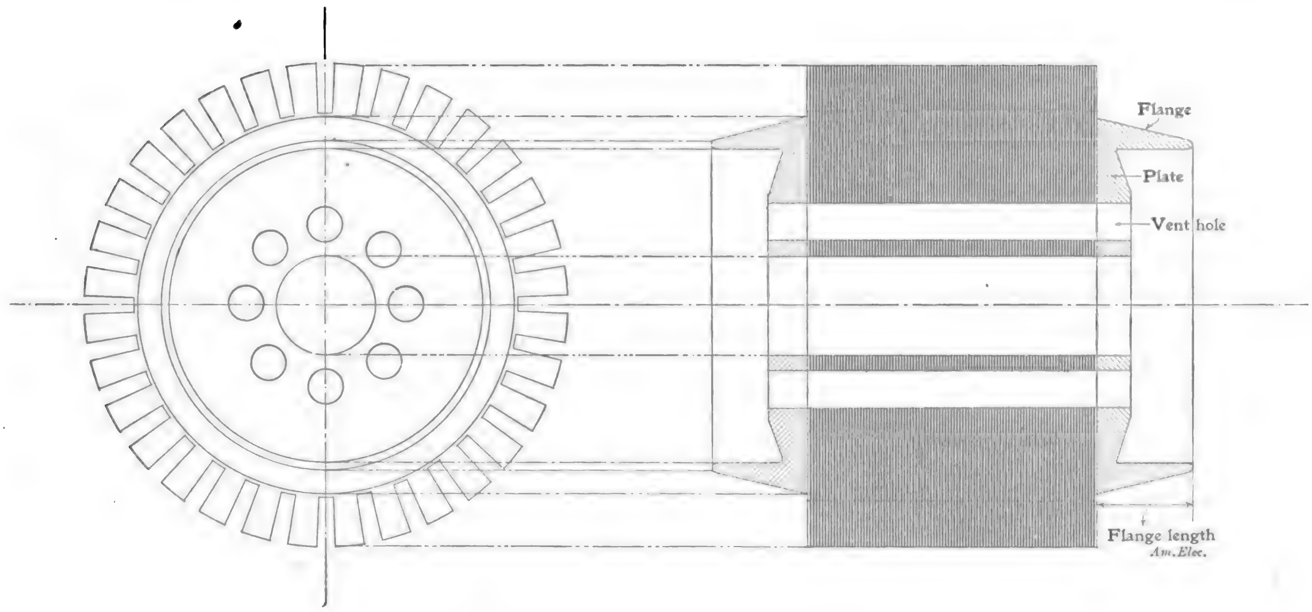

FIG. 15.—ARMATURE CORE CONSTRUCTION.

Besides the central hole, both the discs and the end-plates must have eight ventilating holes of the size specified in Table XII located equidistant and at such distance from the central hole that the edges of the ventilating holes will be ¼ inch from the edge of the central hole. The discs must be keyed to the shaft, and while it is not necessary, the end-plates may be also keyed advantageously. Of course, the key which holds the discs from turning on the shaft would be extended through the end-plates in order to key them, separate keys being unnecessary. The four bolts used for binding the core discs and end-plates together pass through four of the ventilating holes a quarter of a circle apart.

TABLE XII.

Diameter of polar bore =	Up to 8 ins.	8⅛ to 12 ins.	Over 12 ins.
Diameter of vent holes* =	1/2 inch	5/8 inch	3/4 inch
Diameter of core bolts =	3/8 inch	7/16 inch	1/2 inch
End-plate thickness, minimum =	3/8 inch	7/16 inch	1/2 inch
End-plate thickness, maximum =	5/8 inch	11/16 inch	3/4 inch
Flange diameter next to core discs =	1/8 inch less than tooth root circle.	1/8 inch less than tooth root circle.	3/16 inch less than tooth root circle.
Flange diameter at outer edge =	1 1/8 ins. less than tooth root circle.	1 3/16 ins. less than tooth root circle.	1 5/16 ins. less than tooth root circle.

*In all cases, the edges of the vent holes must be 1/4 inch from the edge of the central hole.

Table XIV gives dimensions of the shaft, which is illustrated by Fig. 16. The part indicated by *a* passes through the central hole in the armature core; the part, *c*, through the commutator, and the other parts through the journal boxes. The key seat in the armature part is not shown; its width should be ¼ the diameter of the shaft at *a*, and its length sufficient, of course, to let the key catch all of the core discs (and the end-plates if they are to be keyed). The key should be square, without a head. The core discs must have a key-way punched in the edge of the central hole to fit the key—or more, accurately, to match the key-seat in the shaft. In bipolar machines, each end of the part *a* of the shaft must be screw-threaded for the nuts to clamp the core.

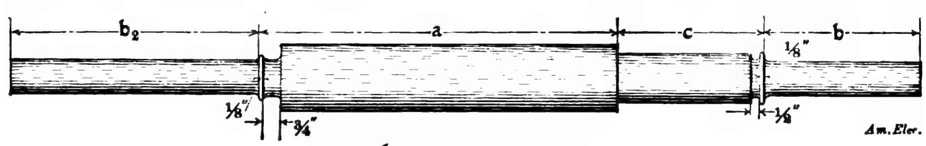

FIG. 16.—ARMATURE SHAFT.

TABLE XIV.
Shaft Dimensions.

Part of shaft (Fig. ..)	*a*	*b*	b_2	*c*
Diameter =	D_0	D_0 — 1/4 in.	D_0 — 1/4 in.	D_0 — 1/8 in.
Length =	Armature core + flanges + 2 ins.	3 D_0 — 1/2 in.	3 D_0 + pulley hub + 1/4 in.	Commutator length over all + 5/8 in.

Note:—D_0 = Diameter of central hole in armature core.

It will be noticed that a groove is turned in the shaft at one end of the part passing through the armature core and another in the far end of the commutator part of the shaft, giving the effect of a rounded collar at the inner end of each of the smallest parts of the shaft. It is important that these grooves be located accurately, for the reason that the collars which they leave on the smaller parts of the shaft are intended to revolve in gaps between the inner ends of the bearing bushings or sleeves and the journal housings, and throw off any oil that may creep along the shaft toward the armature; if the grooves are properly located, the oil will be thrown against the journal housings, and returned to the wells; if they are not, either the shaft will not fit between the bearings or else oil will be thrown off outside of the housings.

Fig. 17 shows the form of journal box recommended by the author. It is of the two-ring self-oiling type, having a brass sleeve or bushing and a split housing. Fig. 17-A is a partly sectional elevation; Fig. 17-B is a part end view and part cross-section on the line $x—y$, except the cap-bolt lugs, which are sectioned on the center line of Fig. 17-A; Fig. 17-C is a partly sectional plan view, the section being on the center line. This box may be used on either a pedestal or a journal bracket of the type in Fig. 18; in the latter case the cap-bolt lugs on the lower half of the housing are unnecessary, the cap-bolts being set into the horizontal arms of the bracket. The bolts would, of course, not need to be as long as specified in Fig. 17; 1¼ inches would be

In machines of 13 to 16 inches polar bore, the shaft and central hole may be made 2 1/2 inches in diameter.

Flange length = armature diameter divided by	5	7

*Subtracting the proper value of K_0 from the tooth-root circle diameter leaves the maximum diameter allowable for the central hole in the armature core.

sufficient. The journal housing is to be made of cast-iron, of course. The sleeve

FIG. 18.—RING BRACKET.

may be held in place by two dowel pins, one set into a hole in the central web of the lower part of the housing and the other in

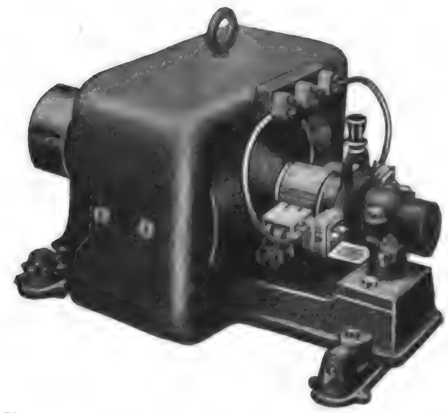

FIG. 19.—BOX YOKE AND PEDESTAL JOURNAL MOUNTING.

a hole in the web of the cap with a driving fit. The pins should fit snugly in diametric-

FIG. 19-A.—PREFERRED FORM OF JOURNAL PEDESTAL.

ally opposite holes in the sleeve web; these holes should not go through the wall of the sleeve. If the builder prefers not to split

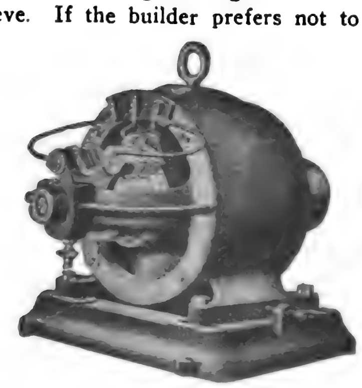

FIG. 20.

the housing but to cast it in a single piece, the box design here shown can be used by making the hole, *h*, at one end of the hous-

ing just 1 inch larger than the bore of the brass sleeve; the hole at the other end should be as stated on the drawing. The larger of these two holes should be at the end of the box farthest from the armature,

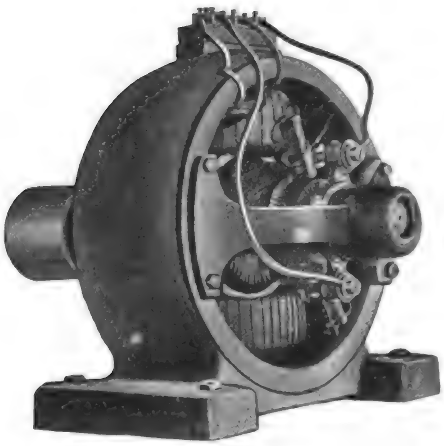

FIG. 21.—CIRCULAR YOKE WITH ARM BRACKET.

the smaller hole being next to the armature at the pulley end and next to the commutator at the other end of the shaft.

The form of journal mounting to use depends primarily on the type of field-magnet

FIG. 22.—SEPARATE BASE AND PEDESTALS.

yoke that is used, and secondarily on the pattern-making ability of the builder. If the box-type of magnet yoke is used, the pedestal form of mounting is the easiest to make, all things considered; see Fig. 19.

FIG. 23.—PEDESTAL MOUNTED ON EXTENSION OF FRAME.

With a circular magnet yoke, either the pedestal or the bracket form may be used, and the bracket form may be fitted to the yoke by means of a continuous ring, as in Fig. 20, or it may be merely a horizontal yoke, bolted to two machined surfaces on the edge of the magnet frame, as in Fig. 21. The ring bracket is much easier to fit accurately to the yoke ring, but it takes a little more material and a trifle more machine work. The bracket in Fig. 21 may also be used with the box-type yoke. The pedestal form may be set on a distinct base, on which the magnet frame is also bolted, as in Fig. 22, or it may be set on an extension cast solidly with the yoke ring, as in Fig. 23. The former is easier to build, but more expensive in material and machine work.

It is impracticable to give dimensions for the arms, webs, walls, etc., of brackets and pedestals of all sizes, but it will probably be of assistance to the amateur to say that arms should be ½ inch to ⅝ inch thick in the center tapering to ¼ inch at the edges; webs and stiffening ribs may be made ⅜ to ½ inch thick where they join the main casting, tapering to 3-16 inch thick at the free edge (or ¼ inch in the center, in the case of a web joining two other members); walls may be from ⅜ to ⅝ inch thick, according to the size of the casting and mechanical stress on the wall.

Commutator and brush-holder construction will be covered in a subsequent article.

BABCOCK BRIDGING TELEPHONE.

BY W. S. HENRY.

The accompanying diagram illustrates a modification of the regular bridging telephone circuit, made by G. Babcock for the Stromberg-Carlson Telephone Manufacturing Company. The principal feature of the modification consists in the interposition of a condenser in the receiver circuit. When the receiver is off the hook the voice current must pass through the condenser, but on account of the high frequency of this current, the condenser increases the impedance of the circuit very little. When the receiver is placed on the hook, the condenser is short-circuited and the bell bridged across the line wires, as in the ordinary bridging instrument. But, if the user forgets to hang the receiver on the hook when through talking, the other bells on the line can still be rung, which would not generally be the case with regular bridging instruments. When the receiver is left off the hook in the arrangement shown in this figure, most of the ringing current would be forced through the bells in the other instruments and hence ring them. This is due to the fact that the frequency of the ringing current is low enough to make the impedance of the circuit containing the condenser very large in comparison with that of bells bridged directly across the line circuit. This arrangement is intended for party line instruments, especially for rural party lines to which more subscribers are connected than to the usual city party line. The condenser should have a capacity of about one microfarad, although one-half microfarad condensers are quite extensively used for this purpose.

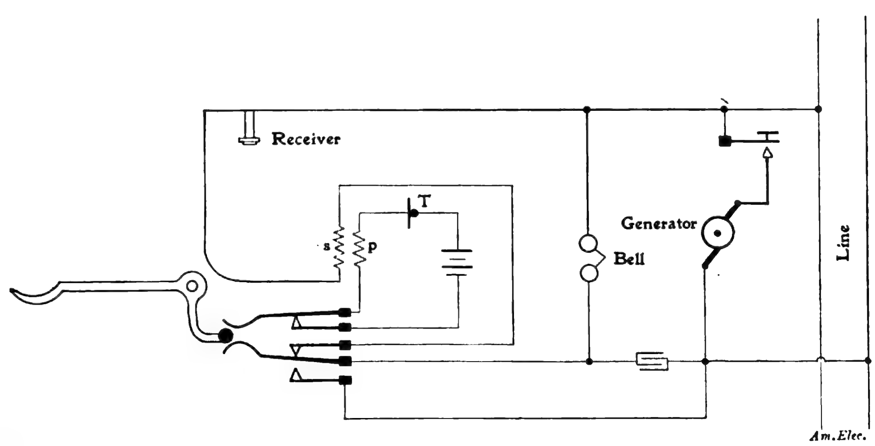

FIG. 1.—BABCOCK BRIDGING TELEPHONE.

ELECTRICAL THAWING OF FROZEN WATER PIPES.

BY C. F. HARDING.

One of the simplest and most useful applications of electricity of recent origin has been in the thawing of frozen water pipes. In most cases water pipes are placed in inconvenient places, requiring costly excavations, or unsightly openings into woodwork or plaster, in order to thaw them by the usual methods. By the application of electricity, however, the work is done in the minimum time without any excavating, leaving the pipe in exactly the same condition that it was before the water in it froze.

The first problem that required the writer's attention was a line of 1½-in. pipe in a hot water heating system which had been allowed to freeze under the floor of a street railway waiting room. The pipe line was about 60 feet in length, and inaccessible, the building having no cellar. The most convenient electric current available for thawing purposes was on the 625-volt trolley circuit.

In order to obtain a good connection between the 300,000 cir. mil cable used and the frozen pipe, the former was soldered into a short nipple, forming part of the radiator connection. This cable was connected to the track. A line from the trolley wire was similarly connected to the other outlet of the same pipe line in series with a water rheostat, a 500-ampere switch and an ammeter. In this case 400 amperes

was applied for the space of about an hour.

Another and much more difficult problem was the thawing of a 2½-in. pipe line 700 feet long connecting a stand pipe with the house supply. This line consisted of a 40-foot vertical section, *A B* (see Fig. 1), of pipe leading to a tank plus the section, *B C*, placed two feet below the surface.

The vertical section was frozen to a height of 40 ft. above the ground, while the horizontal section had been solidly frozen in the ground for a week. The only available current was supplied by a 25-kw. transformer used for lighting the house, and this was placed in such an inaccessible spot that no rheostat could be safely operated in its 2200-volt primary circuit. The primary rheostat method is, in the writer's opinion, the proper one for regulating the thawing current, on account of the small space required, but in this case the more bulky secondary rheostat had to be used.

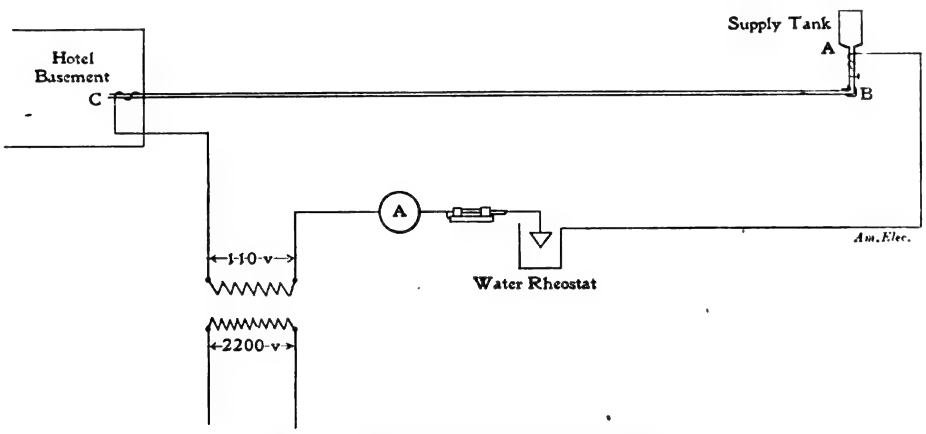

FIG. 1.—THAWING FROZEN WATER PIPE.

The pipe was soon connected to the secondary 110-volt terminals of the transformer in series with the water rheostat, switch and ammeter, by means of lengths of No. 00 cable. The current on the pipe line was gradually increased by means of the rheostat to 270 amperes, at which value it was allowed to remain for about two hours. At the end of this time the vertical section had been thawed as well as the ground in a belt two inches in width surrounding the pipe, although no water flowed in the pipe under a 50-ft. head. The circuit was opened together with the valves in the pipe line, and the heat already imparted to the ground surrounding the pipe soon brought about the desired result, and the water supply was again available.

Although the cost of power in these two cases would, at first thought, seem prohibitive, in order to give this method due consideration, one must balance this expense against the expense of excavating 1300 ft. of frozen ground in the latter case or the tearing down of the under-pinning and the excavating in order to reach the pipe in the former case.

Thus the electrical method of thawing water pipes has to its credit the arguments of economy, facility and celerity, and should, in the future, not only prove profitable to the central station or the plumber, but should also protect the consumer against excessive expense and inconvenience during the dreaded winter season.

REFILLING AND REPAIRING COMMUTATORS.

BY ARTHUR B. WEEKS.

The following experience should be of value where commutator shells are to be refilled, and proves the truth of the oft-repeated statement that the best of material is none too good for a commutator. The writer recalls an instance where not enough pains were taken to ascertain the quality of the copper used in the commutator. The refilled commutator cost one-half the regular price. It appeared all right, was forced to place on the shaft, connections made, and then the trouble began.

As soon as heat was applied through the soldering iron, the made-up mica segments softened, shellac oozed all around the commutator, and the bars fell in, making a most uneven surface. However there was nothing then to be done but to finish the soldering. The commutator nuts were, therefore, tightened all around, and the armature placed in an oven, to bake the shellac dry. This done, the commutator was turned in a lathe.

It would naturally be supposed that this treatment would end the trouble; however, such was not the case, for as soon as the armature was put into the motor it sparked badly. No amount of sandpapering or trueing up, adjustment of holders, changing of brushes, or grinding in brushes, would stop the sparking. In a couple of days, the commutator was so uneven that it was taken out and again turned. The bars were found to be cast, and were very soft. Inside of a week the commutator was entirely worn out.

This experience was very costly, and opened one's eyes to the necessity of securing drop forged or hard drawn copper bars and proper mica segments.

It might be thought that a mistake had been made by the company in using the wrong mica; but a letter from their agent stated that our armature man must have used a blow torch on the comutator to have caused such results, thereby waiving all responsibility in the matter.

For the information of armature repair men not familiar with the different makes of prepared mica, it may be added that commutator mica plate is treated so that there is the merest show of sealing cement, even when subjected to heat. For this reason, a commutator should retain its shape after the leads have been soldered in. Built up mica plate for rings, of some makes, can be cut out of the pasted mica and heated and put under pressure, to form the desired bevel. When ready, it should be baked sufficiently to drive out all moisture.

There is also another flexible mica consisting of two or more layers of sheet mica and a certain cement that will not dry out in a reasonable length of time. This is used by some in making up armature coils, in addition to other insulating materials used. A great deal is claimed for such made-up coils, but it is said they will not withstand much vibration. When new, they will withstand high voltages, but they are short-lived. Where there is the slightest chance for vibration, mica will separate and finally pulverize, and this marks the end of the armature. A good black insulating paint, fish paper and oil paper form probably the best application for railway motors, with a cotton tape over all. Practice varies according to the voltage of the system.

Nowhere is it more important that good mica and good shellac or other varnish be used than in commutator work. Amber mica is most commonly used for commutator segments, as it is softer than white India mica and wears away with the bars. White India is apt to be so hard that the bars wear more rapidly, causing high spots, with consequent sparking, and other bad results.

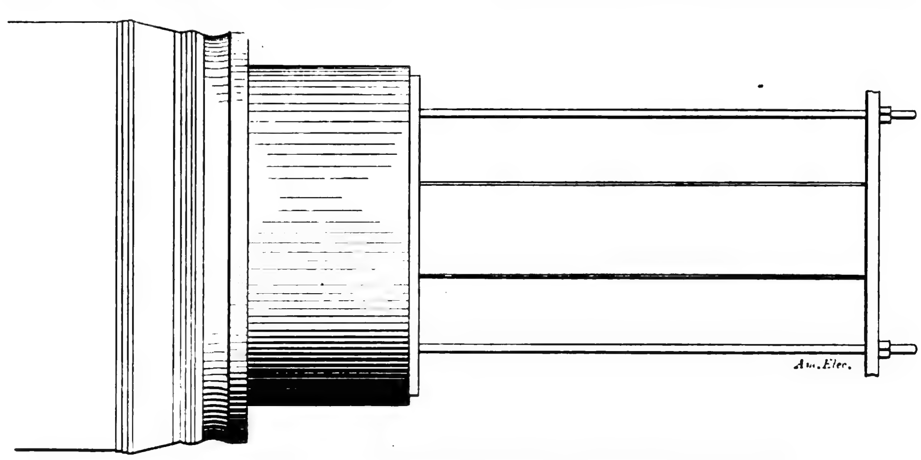

FIG. 1.—METHOD OF REMOVING END COMMUTATOR LOCKING RING.

A good, soft white mica for commutator segments is rare; pasted mica or built up mica being used altogether for this class of work. It is bought by the pound. Prepared mica of the proper thickness can be purchased in sheet form, and segments of the desired shape cut out for any and all repair work. It has often been required to repair a place in a commutator between bars, where the mica may have been burned out, often because of an open circuit in a coil. The wire to a commutator segment is often broken, causing such troubles. After attending to the broken wire, a defect like this is often repaired by filling the

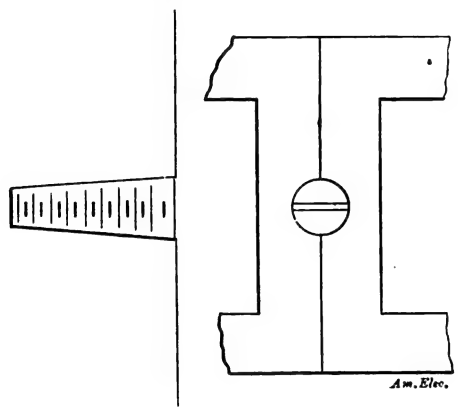

FIG. 2.

cavity (after a thorough cleaning out) with alcohol shellac and pulverized mica, or alcohol shellac and plaster of paris. In small, smooth cavities, this will not stick, and the next best plan is to insert a new mica segment—a simpler operation than is generally supposed.

To do this, the armature is removed from the frame, the nuts loosened which clamp the segments in place, and the end commutator ring removed. The bars affected are pulled back, the old material removed and all mica scraped from the bars. A little shellac or similar lac should be used on the bars, and the new mica segments inserted. The method of removing the end commutator locking ring is familiar to the older men in the work. If there are no holes drilled in this ring diametrically opposite each other, into which bolts can be screwed, such holes must be drilled and tapped. The size of bolts depends upon the

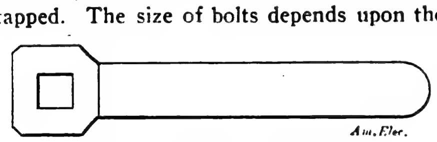

FIG. 3.—SPECIAL WRENCH.

size of commutator. Screw the two bolts into the ring and place a flat piece of iron across the end of the shaft, with holes in the strap for the bolts to pass through. After the lock nuts are removed from the bolts, screw down on the nuts of the two bolts mentioned. After a little effort, the ring will come out. Tap it lightly with a hammer, and see that the ring comes up equally all around, and avoid binding.

There is a style of locking ring which is screwed on, instead of being secured with bolts. In this case, a spanner wrench must be procured, fitting into holes in the ring. After a couple of good, smart blows on the wrench with a hammer, the ring will usually start. When the prongs are bent out of shape, the tool should be dressed, otherwise the holes are liable to be ruined, and it will be next to impossible to get the wrench to hold. Make the mica segments for repair work of this kind just a little larger than the original, especially on the top face, for the ring may not go back in place exactly as when first assembled. With care, it will not be necessary to turn the commutator after this operation. Do not separate any of the bars not affected, for the chances are that if this is done, the commutator will require turning. Cut away the twine or binding wire back of the commutator, should it interfere with the work. Cutting or unsoldering the armature leads will not be necessary, excepting in case of large armatures, where the leads are too large to be bent back. Disconnecting is in these cases the only alternative.

This method of removing and replacing mica is applicable to the copper segments as well. This is often necessary in street railway commutator repairs, when a bar or bars become so highly discolored as to become soft. They are made thus at times, when an armature is grounded, and continued attempts to "make the thing go" send so much current through the bars directly, as the armature will not turn, that there is an intense heat under the brushes, and they glow like an arc light. Coils are very liable to be burned out at the same time. A voltmeter test will indicate the condition of the insulation.

There is a little trick not commonly known, to prevent side play, when lost motion has once set in between two surfaces, such as in a ring armature, where the laminations or core have worked loose on the hub or spider. A good method of repair, and one that can be effected in a very short time, and made to stay, has puzzled many. The method is illustrated by Fig. 2 herewith.

Turn up in a lathe a taper bolt, cutting a regular gas pipe thread thereon. Make the bolt headless; get the size of the hole to be drilled by means of thread calipers, at about halfway of the tap. Then when the two surfaces are in their original position, drill and tap the hole. Try the bolt from time to time in the hole. Run the bolt just below the surface, and rivet over the metal with a hammer, so that under no circumstances can the bolt back out. A favorite method with machine hands is to prick-punch in several places around the bolt head, at the intersection of the bolt and hole. The only objection to this plan is that should it be necessary to replace a bolt, it is next to impossible to withdraw it. It is often necessary to drill the bolt out.

If it is required to remove the bolt, by merely setting the metal over it, the metal can be cut away with a small, sharp cold-chisel; then use a large screwdriver, which is best made of a ½ to ⅝ square piece of steel, and use a monkey wrench or special wrench.

To drill out such a headless bolt or screw, where it is impossible to get the drill in a center made with a prick-punch, it is necessary to fill the slot in the screw to obtain a center. Fit a piece of iron into the slot, center it and drill. Sometimes a bolt is best removed by drilling a hole therein part way, then driving a square tool into the hole, then by means of a wrench as before described, back out the screw. The tool should be slightly tapered, and large enough to drive very tightly into the hole.

When this method fails to remove a bolt, use a drill as large as possible, and run it to the bottom of the hole. Center the drill exactly, and take care not to cut away any of the thread. Nothing but the shell of the bolt now remains. Use some sort of pry to loosen this shell, which can be easily removed. A tap should then be run into the hole to smooth it.

SWITCHBOARD CONNECTIONS OF COMPOUND-WOUND GENERATORS.

BY H. M. GASSMAN.

Judging from the number of mistakes which are made in connecting compound wound generators to switchboards, very few men seem to have a clear understanding of the correct scheme of connections. The reason for this is due to a great extent to the confusion caused by introducing the idea of polarity when speaking of the terminals of a generator.

The writer finds it advantageous to drop the idea of polarity, and speak of three leads running from the generator as

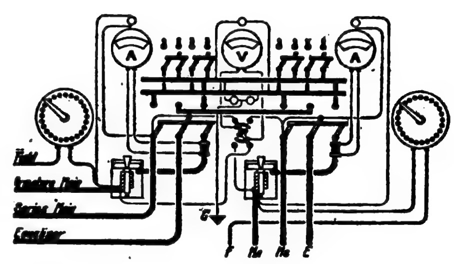

FIG. 1.—SWITCHBOARD CONNECTIONS OF COMPOUND-WOUND GENERATORS.

"equalizer," "armature" and "series" main. The "armature" main is the one running direct from the armature terminal to the switchboard, and the "series" main the one running direct from the series coil. Whatever the polarity of the "series" main, the "equalizer" will be of the same polarity and the "armature" main of the opposite polarity.

Further, the scheme of connections is not changed, even though the polarity of the generator be reversed (except that meter leads will have to be reversed to give the right deflection on the scale).

The ammeter and circuit breaker *must always* be connected in the "armature" main.

The "series" main may be connected to the ground feeder or to the line feeder. If the equalizer is not run to the switchboard the equalizer switch is mounted on a pedestal near the generator.

When the "series" main is connected to

the ground, there may be quite a saving in cable if the connection be made direct to the ground feeder without going to the switchboard. In this case the circuit breaker must be connected in series with the armature between the armature and the equalizer terminal. This circuit breaker and the equalizer switch would then be mounted on a panel near the generator. No circuit breaker on the switchboard would then be required.

When the "armature" main is connected to the ground, it must be run first to the switchboard before making the ground connection, in order to reach the ammeter, unless the ammeter shunt be located near the generator, in which case an auxiliary panel having the circuit breaker and an equalizer switch could be located near the generator and the same saving of cable be made.

It is very desirable to have the "series" main connecting to the feeders in railway plants where lightning is liable to do damage. In case the lightning arrester is inoperative, the lightning would not damage the armature, as it would not reach it, because of the self-induction of the intervening series coil. For this reason largely the majority of electrical manufacturers have recommended that their machines be so connected.

So far in this discussion the matter of polarity has been of no consequence, but for sake of uniformity it is desirable that it be made to conform to the almost universal practice of making the line feeders positive. Plants have been run intentionally and unintentionally with the feeders negative. The writer has never found a satisfactory explanation of why the positive polarity was adopted rather than the negative. This question probably was decided in the same way that 110 volts was determined as the standard for incandescent lighting.

If the polarity of a generator does not agree with the polarity desired on the feeders, it is a very easy matter to reverse the polarity of the generator simply by magnetizing the fields in the opposite direction.

CHANGING MAGNET WINDINGS FOR DIFFERENT VOLTAGES.

One frequently has occasion to rewind a magnet coil for some voltage other than the one for which the magnet was originally wound, keeping the magnetizing power of the coil practically unchanged. While the formula for calculating the size of wire to be used in the new winding is not at all complex, the calculation is a little tedious because of the number of figures contained in the number of circular mils of wire cross-section. Moreover, if standard sizes of wire are to be used, it is usually impossible to make the new size of wire fit the new voltage accurately. In view of this latter feature, results just as satisfactory in practice can be obtained by means of the accompanying set of "scales" as by the most elaborate calculation. The scales are based on the average relation between the cross-sections of successive sizes of copper wire drawn to B. & S. gauge; the average ratio of one cross-section to the next larger one in the list of gauge numbers is 0.793, and the scales are computed for voltages of the same ratio between successive values in the downward (decreasing) direction.

For use, the group of voltage scales should be cut out and pasted on a piece of extra-heavy cardboard, and the wire scale cut out and pasted on a thin but substantial piece of cardboard or a very heavy piece of drawing paper. The scale of wire sizes can then be set against any one of the voltage scales with the scale divisions matching. In order that the scales may be cut out without spoiling the page on the other side of this leaf, they have been reproduced on page 120. The following examples will serve to make use of the scales clear to those unfamiliar with the principle on which they are based:

Voltage Scale. A	Voltage Scale. B	Voltage Scale. C	Voltage Scale. D	Voltage Scale. E	Voltage Scale. F

A magnet winding of No. 23 wire intended for 115 volts terminal e.m.f. is to be displaced by a winding for 6-volt battery current. Set the wire scale against voltage scale *D* with No. 23 opposite to 115 volts; there is no 6-volt value in the scale, 5.65 volts being the nearest number; opposite this is found No. 10, which is the size of wire to be used. Keeping the scales set as described, it will be found that the following windings are possible: No. 15 wire for 18 volts, No. 17 wire for 27 volts, No. 26 wire for 230 volts, and so on.

Again, suppose a winding of No. 14 wire for battery current of 6 volts is to be substituted by a winding for 120 volts. Setting the wire scale against voltage scale *A*, with No. 14 opposite 6.2, one finds that No. 27 wire is suitable for 126 volts; but 126 volts are not available, so that scale *E*, which includes 120 volts exactly, should be used. Setting No. 14 opposite 5.9 in scale *E*, No. 27 is found opposite 120 volts, so that the first result was correct even though the scale values were not exact. It will usually be found best, however, to use the voltage scale which contains the exact value of one of the voltages with which one is dealing.

It should be remembered that the insulation on small wire sizes takes up a much larger proportion of the cross-section of a magnet coil than the insulation on large sizes; consequently, a coil of given dimensions wound with small wire will take more *watts* than one wound with large wire, if each is supplied with the proper voltage to give the same ampere-turns as the other. As a result of this, in changing from a low voltage to a higher one, it will be found that the winding for the high voltage heats more than the original winding for the lower voltage. When it is possible, therefore, the length of the new magnet coil parallel with the core should be made greater than that of the original coil, when the winding is changed to a higher voltage. The relation between the length of the new coil and that of the original one should be approximately as follows:

$$L_n = \frac{E_n\, d^2_n}{E_0\, d^2_0} \times L_0$$

in which L is the length of coil along the core, E is the voltage, and d is the diameter of wire *over its insulation;* the subscripts n and o indicate, respectively, the new and old values. It is, of course, unnecessary to make any change in the length of coil when changing to a voltage that is lower than the original voltage. In this case the new winding will heat less than the old one.

To get more Heat from a Radiator.—The electric fan that is used to keep one cool during the summer can also be used advantageously to heighten the temperature of a room during the winter, where the steam radiator is either too small or the steam pressure too low to maintain a comfortable temperature. Place the fan so that the current of air will blow against a large surface of the radiator and in a very short while the room is changed from cold to warm.

AVERAGE LENGTH PER TURN OF WIRE IN MAGNET COILS.

In order to determine the exciting power of a magnet coil taking current at a stated voltage, it is necessary to know the average length per turn of wire in the coil. For round coils—that is, coils wound on a bobbin or former of circular cross-section—the mean length per turn is equal to π times the sum of the bobbin diameter + the coil depth. If the bobbin or former on which the coil is wound be made 1/8 inch larger in diameter than the magnet core, sufficient mechanical clearance will be obtained for all ordinary conditions. The accompanying table is computed on this basis, and will be found extremely useful in connection with magnet windings for round cores. It should be kept in mind that the "Core diameter" in the table is the *magnet* core diameter, not that of the bobbin.

TABLE I.

Mean Length per Turn of Wire in Round Magnet Coils.
Diameter of Coil Bobbin to be 1/8-inch Larger than Magnet Core.

DRYING OUT MAGNET COILS.

BY W. B. ARTHUR.

The water rheostat is used for many purposes, but the following will be new to many, probably. The tank shown in Fig. 1 is of galvanized iron. Water is let into it at the top in a steady stream, governed by the valve shown. At the bottom of the tank is a pipe about one foot long, also containing a valve; just below this drain pipe is a pan, with outlet through the floor into a drain pipe to the sewer. The tank thus arranged is free to be moved wherever desired after emptying out the water, as no pipes are positively connected to it.

The wires are plainly shown in the illustration. They enter the Edison cut-out in the upper right hand corner of the slate panel, and thence pass to the switch. One wire goes to an iron plate in the bottom of the tank; it could have been connected directly on the tank, somewhere near the top. The other wire is connected to the plate suspended by a rope above the tank, and the amount of current passing is regulated by varying the depth of the plate in the water. From the latter plate the wire goes to a coil of wire on the bench. The other end of the wire from coil is connected to the other side of the switch. See Fig. 2 also.

In every electric light or power plant coils are wound and usually immersed in an insulating varnish of some sort. All

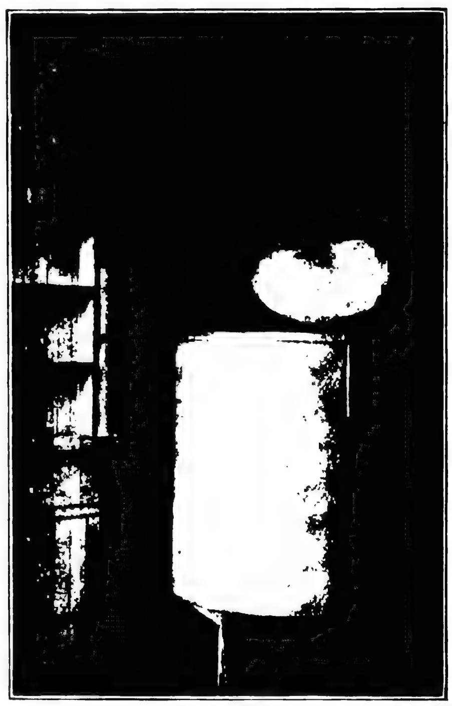

FIG. 1.—WATER RHEOSTAT.

of these produce more or less verdigris, but drying out the coil quickly will reduce objectionable effects very materially, if not altogether obviating them. Steam heat or even heat of any kind does not dry as completely and effectually as does a transmission of electric current through the coil itself. This has been repeatedly and satisfactorily demonstrated. Current can be applied as desired; but if no ammeter is in circuit, one must gauge the temperature of the coil by feeling it. The coil must not be heated too severely at the start, lest it become damaged. It may steam a great deal, and still be all right. A number of similar magnet coils or armature coils, if connected in series will, of course, take the same current, and all can be dried at the same time.

It is customary to dip small coils.. There are several insulating varnishes which, if not baked too long, will still retain their elasticity; but if the baking is stopped too soon, verdigris will surely follow by any

method of drying. A great deal has been said about the elasticity of clear insulating varnishes, but as far as their use on coils for field magnets and armatures is concerned, elasticity does not count for much. The coils should be baked to a deep brown—not a straw color. If one has any doubts about the results of the electric drying, they can be dispelled by trying it on a coil, and at the same time baking another coil in an oven for the standard length of time and at the required temperature. If both are put away on a shelf in a dry place, and examined at the end of three or four weeks or more, the excess of verdigris on the oven-baked coil will be conspicuous.

The current used in the case illustrated was 110 volts alternating. The best practice is to have an ammeter in circuit; none is shown here. A tube thermometer is also greatly advantageous.

Every electric repair shop should have its water rheostat. It is indispensable for

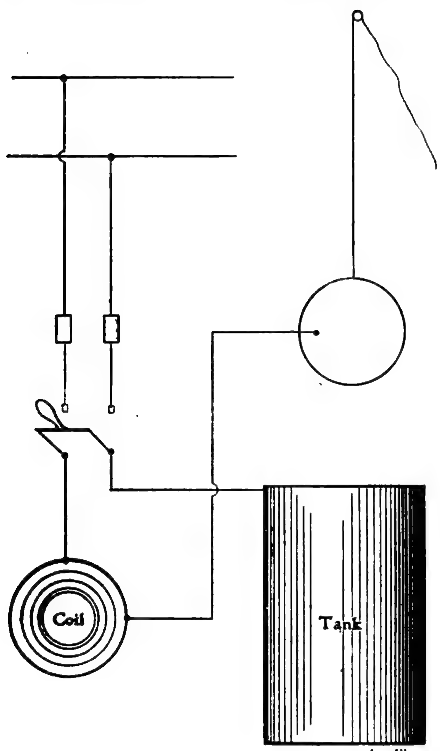

FIG. 2.—DIAGRAM OF CONNECTIONS.

such places. It can be used for testing motors and meters; and one can test a single-phase wattmeter to ascertain the proper connections to be made before connecting the meter on the system, to avoid the cut-and-try method which wastes both time and material. There are men who can do a fine piece of electric wiring for an office or factory, but who do not know how to connect up a wattmeter, especially a two-phase meter. The water rheostat can be used to show the method of connecting.

Referring again to coils dried by current passed through them, it should not be supposed that the interior of the coil has the same color as the exterior—far from it. That is one reason why the baking is not thorough. Moreover, some varnishes which are suitable for cloth and paper are quite unsuited for armature or field magnet coils; special kinds are manufactured for every sort of work.

Principles of Electrical Apparatus

EFFECT OF SELF-INDUCTION IN THE ROTOR OF AN INDUCTION MOTOR.

The rotor of an induction motor is subject to self-induction, just like the armature of a direct-current motor. This effect, however, is greater in degree and more disadvantageous in the induction machine, as will be shown in due course.

The current induced in the rotor conductors by the rotating magnetic field alternates at a low frequency, as explained last month, and as the conductors form closed circuits about an iron core they possess considerable inductance, which results in not only reducing the volume of current flowing, but in throwing that current out of phase with the induced e.m.f. that forces it through the rotor conductors. This phase displacement is illustrated by the diagrams, Figs. 1 and 2, in which a single turn or loop of the rotor "winding" is shown. (It is much easier to follow the actions in the rotor by considering a single loop, and the result is practically as accurate as though the whole squirrel cage were considered. It also simplifies matters to study a bipolar field, and this will be done throughout the Lessons on this subject. The only difference in the actions of bipolar and multipolar fields is in the rotative speed.)

In Figs. 1 and 2 a rotor core is represented having two conductors joined at the ends by wires across the heads, thus forming a closed loop. The inner edge of

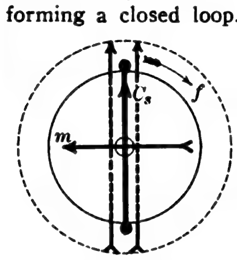

FIG. 1.—CURRENT IN PHASE.

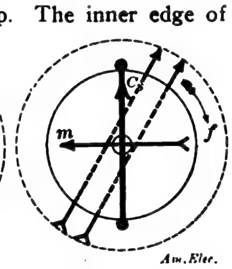

FIG. 2.—CURRENT LAGGING.

the stator ring is indicated by the dotted circle, the air-gap being exaggerated in order to show the action of the rotating field flux. The plane of this flux, as well as the position of its central or densest part, is indicated by double arrows across the air-gap, and the direction of rotation by the curved arrow, *f*. The e.m.f. induced in the loop will have its maximum value when the central zone or densest part of the flux, indicated by double arrows, passes across the conductors of the loop and with no self-induction, the current would also attain its maximum value at this instant, as indicated in Fig. 1, where the arrow-head, C_s, indicates the flow of induced current in the rotor loop. This current induces a cross magnetic-flux in the rotor core, as indicated by the arrow, *m*, and the pull or torque between this and the field flux is greatest when the planes of the two are a quarter of a mechanical cycle apart, as shown; consequently, the torque is maximum when there is no lag in the current.

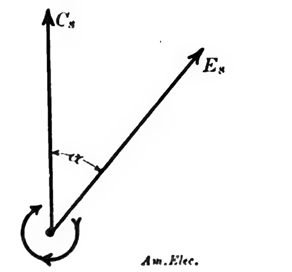

FIG. 3.—ILLUSTRATING LAG ANGLE.

Self-induction, however, produces a lag in the current (the phase of the induced e.m.f. remains coincident with the mechanical phase of the field flux), and then the current in the loop does not attain maximum value until the rotating flux has passed the conductors, as indicated in Fig. 2; then the angle between the field flux and the cross flux is greater, as shown, and the torque is less. The exact relation between the current lag and the torque may be shown by the use of a few simple formulas. As it is awkward to compare the current phase with the position of the field flux in space, the phase of the induced e.m.f., which rises to maximum in unison with the passage of the flux, will be taken as the basis of comparison.

If the difference of phase between the current, C_s, and the e.m.f., E_s, which forces it through the loop be represented by two vectors, as in Fig. 3, the angle, *a*, between the vectors will be such that its cosine is equal to the resistance of the loop divided by its impedance; thus:

$$R_s \div Z_s = \cos a.$$

As stated previously, the torque is maximum when the current is in phase with its e.m.f., and it decreases directly in proportion to the cosine of the angle between the two vectors representing the difference of phase between the current and the e.m.f. Thus, if there were no lag in the current, the torque exerted on one loop, in pound-feet, would be equal to $.707 \times \Phi \times C_s \times k$. In this expression, Φ is the number of magnetic lines in the rotating field flux; C_s is the current in the conductor loop, and k represents the constants necessary to reduce absolute units to practical ones. As there is always a current lag, however, the torque can be represented by the expression: $T = .707\ \Phi\ C_s k \cos a$. As the cosine of the angle of lag is equal to the resistance of the loop divided by its impedance, the last equation may be changed to read:

$$T = .707\ \Phi\ C_s \frac{R_s}{Z_s} k.$$

Furthermore, as the current in the loop is equal to the e.m.f. divided by the impendance, $C_s = E_s \div Z_s$ and as the e.m.f., E_s, is equal to $4.44 \times f_s \div 100{,}000{,}000$, the current, C_s, is equal to $4.44 \times f_s \div 100{,}000{,}000 \times Z_s$, and the equation for pound-feet of torque may be again changed to read thus:

$$T = \pi \Phi^2 f_s \frac{R_s}{Z_s^2} k \ldots\ldots\ldots\ldots (5)$$

in which k now includes also the numerical divisor 100,000,000 (or more accurately its reciprocal) in the expression for e.m.f., and f_s is the frequency of the current in the rotor loop. This formula shows that increasing the resistance of the rotor loop will increase the torque, while any increase in the impedance of the rotor loop will decrease the torque. Now, impedance consists of resistance and reactance combined, so that the resistance cannot be increased without increasing the impedance also, but it must be remembered that the increase in impedance is not directly proportional to the increase in resistance. Separating the impedance into its component parts, formula (5) develops into

$$T = \pi \Phi^2 n_s \frac{R_s}{R_s^2 + X_s^2} k \ldots\ldots (6)$$

A rough example will serve to show that if the resistance equals the reactance, a change in either direction will reduce the torque; consequently, increasing the rotor resistance will increase the torque only up to the point where the resistance and reactance become equal—beyond that, it decreases the torque. Example: Resistance $= 2$; reactance $= 2$; as impedance, Z, is equal to $\sqrt{R^2 + X^2}$, in this case its value is $\sqrt{4+4} = 2.8284$, and the fraction, $\frac{R_s}{Z_s^2}$, in formula (5) has a value of $\frac{2}{8} = 0.25$. Now, suppose the resistance were increased to 2.1; then the impedance would be 2.9 and the fraction $\frac{R_s}{Z_s^2} = \frac{2.1}{8.41} = 0.2497$. Again, suppose the resistance reduced to 1.8; then the impedance would be 2.69, and the fraction $\frac{R_s}{Z_s^2} = 0.2486$. In both cases, the value of $\frac{R_s}{Z_s^2}$ is less than when the resistance and reactance are equal, and the torque increases or decreases directly with an increase or decrease in the value of this fraction.

Formulas (5) and (6) also show that if the other factors remain unchanged, any increase in the frequency, f_s of the rotor current will increase the torque. This confirms the explanation, in the preceding article, of the increase in torque due to increase in "slip," the rotor conductors being "cut" by the magnetic field at a higher rate as the difference between their rotational velocities increases. Following out this line of reasoning, the torque would be maximum when the rotor stands still, as the conductors would be "cut" at the full frequency, f, of the magnetic field.

This would be true if the rotor had no inductance and consequently no reactance. ($X = 2\pi f L$.) But it has, and at standstill the reactance, with ordinary frequencies, may be twenty or thirty times as high as at full speed. This great reactance throws the rotor current so far out of phase with its e.m.f. as to decrease the torque to a very small value, notwithstanding the great rush of current due to the high e.m.f. induced in the rotor by the high rate of "cutting" between the rotating field and the conductors. Another rough example will serve to illustrate this point. Formula (6) shows that the torque is directly proportional to

$$f_s \frac{R_s}{R_s + X_s^2}$$

Now suppose that the resistance, R_s, of the single loop is 0.005 ohm and its inductance, L_s 2½ millihenrys, or 0.0025 henry. With a primary frequency of 60 cycles and a 5 per cent. slip at full speed, the rotor frequency will be $.05 \times 60 = 3$ cycles, and the reactance ($2\pi f_s L_s$) of the one loop will be $2\pi 3 \times 0.0025$, or 0.047124 ohm. Substituting these values in the above expression, we get

$$f_s \frac{R_s}{R_s^2 + X^2} = 3 \times \frac{0.005}{0.000025 + 0.00222} = 6.68$$

so that the torque is $6.68 \pi \Phi^2 k$ at full speed.

At standstill the rotor frequency is the same as the primary frequency—60 cycles. The reactance then will be $2\pi 60 \times 0.0025$, or 0.9425 ohm, and

$$f_s \frac{R_s}{R_s^2 + X_s^2} = 60 \times \frac{0.005}{.000025 + .8883} = 0.3377.$$

Consequently, the torque at standstill will be only $0.3377 \pi \Phi^2 k$ pound-feet, the relation between this torque and the full load torque having the ratio, roughly, of 0.338 to 6.68. It is because of this effect that the rotors of large motors are provided with coil windings and slip rings whereby an external resistance may be inserted in the rotor circuit. Suppose, for example, that the terminals of our single loop were led to two slip rings (like the collector rings on an alternator) and the brushes of those slip rings connected to a resistance of 0.935 ohm; then the total resistance would be 0.94 ohm, the reactance at standstill, 0.9425 ohm, and the starting torque, $31.8 \pi \Phi k$ pound-feet, or nearly 100 times the standstill torque that was obtained without external resistance.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Charging Storage Batteries.

In response to Mr. Bryan's letter last month inviting discussion on the storage battery, I would say that the voltage per cell should be 2.5 volts before the charging circuit is disconnected and not after; this is explicitly stated in papers issued by the Electric Storage Battery Company.

In experimenting with two Hatch cells, the highest voltage obtainable per cell at normal charging rate was 2.63 volts, which dropped to 2.28 volts on open circuit immediately after charge; on closed circuit it rapidly fell to 2 volts per cell. In the same experiment with a new battery of Chloride accumulators 2.6 volts per cell before disconnecting was all that could be obtained without going beyond the danger point.

As the editor stated, "The voltage is not the only guide to full charge"; if a portable voltmeter with a low-reading scale is not at hand, the density of the electrolyte is a good indication. At full charge it should be 1.200 specific gravity, and the battery should never be discharged below 1.175. To maintain a battery in the best condition and keep a check on its action, records of the voltage and the density of the electrolyte should be kept, by this means any irregularity can be detected almost as soon as it occurs.

The color of the plates is also a guide as to the state of the charge; the positive should be a deep brown, and the negative a light slate color when full charge is obtained. The battery will also gas freely near the end of charge. The last two indications are not as reliable as the first two, which should never be omitted if the instruments (voltmeter and hydrometer) are available.

The foregoing is applicable only to a battery in good condition; the voltage of a battery badly sulphated, or of one that has been overloaded or continually overcharged, cannot be brought up equal to one that has had good care and is free from these faults. Age will also slightly decrease the voltage of a battery.

I have found that the temperature of the battery room has an effect on the voltage of a battery without affecting its efficiency to any great extent. I recently had charge of three batteries of Chloride accumulators, of which two were in rooms where the temperature hardly ever exceeded that of the outer atmosphere; the voltage per cell in these batteries always came up to the standard—2.5 volts. The third battery was in a room, the temperature of which ranged from 90 degs. F. to 104 degs. F. The voltage per cell of this battery never exceeded 2.35 volts with charging current flowing. And in a test of the efficiency of the batteries the latter showed only 0.35 per cent. less than the other two.

I may also state that my experience with men handling storage batteries (which I admit has been limited) is just the reverse of Mr. Bryan's—they were very decided on the particular point in question.

F. SCHROEDER.

Fort Revere, Mass.

Mr. Malcolm's Motor Connections.

I herewith submit a solution (Fig. 1) of the problem in motor connections, which appeared in your January issue. The field winding of the small machine, which I assume is shunt-wound, is connected in parallel with that of the 5-h.p. motor. The armature is connected in parallel with the large armature, but outside the speed regulator, *R*, so as to be independent of the latter. The one starting box controls both motors simultaneously.

EDGAR S. BECK.

Treichlers, Pa.

The accompanying diagram (Fig. 1) shows probably the best solution of the problem in motor connections by Mr. Geo. W. Malcolm. The terminals of the small motor are connected to the corresponding terminals of the large motor, the speed-regulating rheostat being considered included in the system of the large machine. The starting box will then start both motors together while the speed rheostat will affect only the 5-h.p. machine.

H. A. CLARK.

Chicago, Ill.

The accompanying sketch (Fig. 1) is submitted as a solution to the problem in

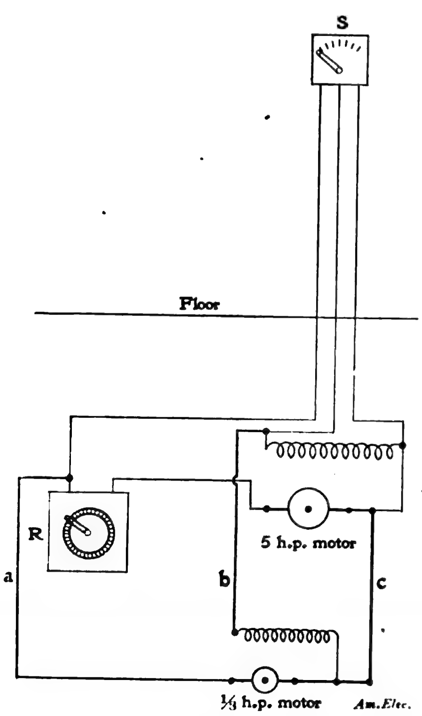

FIG. I.—SOLUTION OF MR. MALCOLM'S PROBLEM.

motor connections published last month in the AMERICAN ELECTRICIAN, and is practically self-explanatory. Instead of connecting the armature of the small motor in series with the resistance in the starting box, it could be connected direct to its field on the left-hand side, and the wire running to the rheostat, *R*, could be dispensed with, because I hardly think it would be

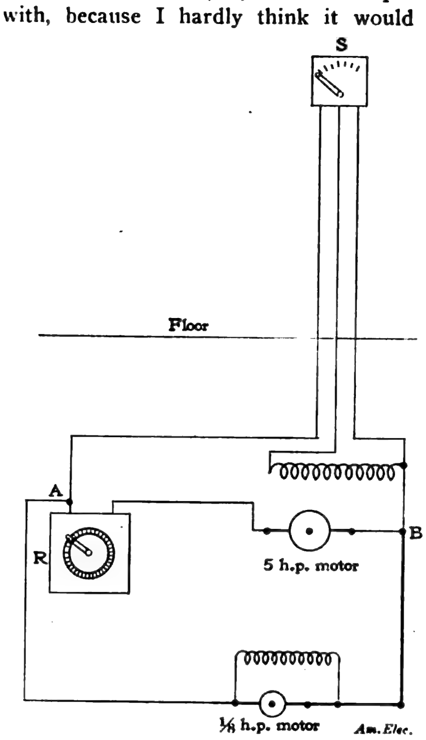

FIG. 2.—SOLUTION OF MR. MALCOLM'S PROBLEM.

necessary to use a starting box on so small a motor.

J. D. CONVERSE.

Chicago, Ill.

I enclose a diagram of connections (Fig. 1) which seems to fit the case described in Mr. Malcolm's letter last month. The diagram is self-explanatory. I have assumed that the small motor is shunt-wound, like the large one; if it is not, the wire, *c*, should be omitted and the wire, *b*, carried to the right-hand brush of the large motor instead of to its field winding terminal.

JAMES B. DILLON.

Louisville, Ky.

[Mr. Dillon's diagram was identical with Fig. 1, except that fuses were included in the leads, *a*, *b*, *c*.—EDITOR.]

Enclosed are two diagrams of connections (Figs. 1 and 2) submitted as solutions of Mr. Malcolm's problem, which appeared last month. Fig. 2 is possibly the simpler arrangement. The sketch is self-explanatory. In Fig. 1 the shunt field current of the $\frac{1}{8}$-h.p. fan motor adds its quota of current to the electromagnet on the starter, *S*, and may be objectionable on account of the heating effect on the electromagnet due to this extra current.

G. E. FREASE.

Youngstown, O.

Please find enclosed a solution (Fig. 2) of Mr. Malcolm's problem in motor connections published last month. The shunt field winding of the small motor is connected permanently to its brushes, and the complete motor is controlled by the starting box upstairs, but not by the speed-regulating rheostat, *R*.

J. H. GAUSE.

Wilmington, Del.

The accompanying diagram (Fig. 2) is submitted as a solution of Mr. Malcolm's problem in motor connections published in this department last month. It is based on the assumption that the starting box is of the no-voltage release type; also that the regulating box has no "dead" or off point. After the motors are started the voltage across points marked *A* and *B*, would remain constant regardless of the position of the contact finger on the regulating box, hence the $\frac{1}{8}$-h.p. motor would run at constant speed.

In consideration of the fact that a small motor will pick up speed much faster than a large motor, it would not be necessary to run a separate wire to the shunt field winding of the $\frac{1}{8}$-h.p. motor.

WM. MERRILL.

Wilmington, Del.

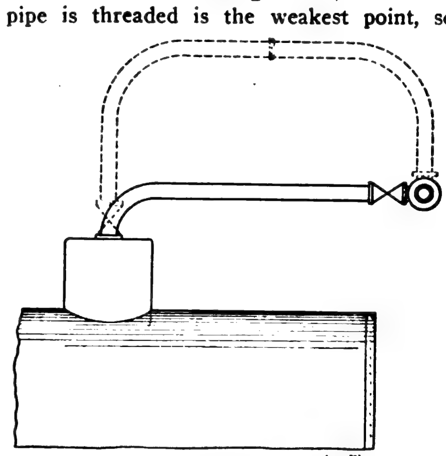
Enclosed find my solution (Fig. 1) to Mr. Malcolm's problem in the January number. The way I understand this problem is that Mr. Malcolm intends using one starting box for both motors. Practically this makes one piece of apparatus out of the two units, and for that reason I have omitted individual switches and fuses.

CHAS. B. SMEETH.

Ironwood, Mich.

Boiler Connections.

In reply to Mr. Walthall's question about boiler connections last month, the arrangement shown in the first case by solid lines would be best. Of course, it does not allow for expansion, but the pipe would be less liable to be broken than that shown by dotted lines. In the first case, the thread where the pipe enters the dome is subjected to a shearing strain, and would stand better than in the second case where the threads have to stand a bending strain; where the pipe is threaded is the weakest point, so



BOILER CONNECTIONS.

that the pipe would break, the break occurring on the sides facing each other. As to placing the valve as shown by dotted lines, if this boiler were shut down while other boilers in the battery were supplying steam, there would be condensation losses in this length of cold pipe. On the other hand, in the first case, it would be necessary to shut the boiler down to do any work on its delivery pipe.

HERBERT B. BRAND.

Brooklyn, N. Y.

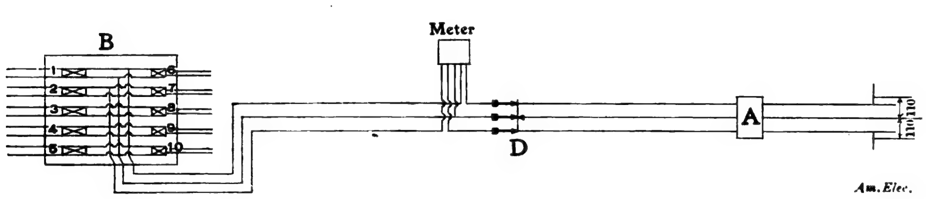
Referring to Mr. Walthall's boiler connections, I would much prefer the long bend shown by the dotted lines, but would put a reverse bend in between the end of the long bend and the boiler dome, and another between the other end of the long bend and the main header. This would make the intake and discharge of the boiler connection horizontal instead of vertical. The advantages would be that the steam flow would be better and the long bend would be less liable to break off in the threads on account of expansion and contraction. If one valve is to be used, it should be next to the main header, to keep steam from other boilers out of the long bend when this particular boiler is shut down. Two valves would be much better practice—one at each end of the long bend.

Los Angeles, Cal. SAMUEL TROTMAN.

An Insulation Resistance Problem.

I enclose a sketch of the main and branch circuit wiring in a building in this city, in testing which for insulation resistance I find a peculiar condition. The service is three-wire, 110—220-volt with the neutral conductor grounded at street entrance. The branch circuits are all two-wire 110-volt. All wires are installed throughout in iron conduits, which are securely grounded.

In connecting a voltmeter across the main cut-out, *A*, with one terminal to the + side of service and other connected to the entire system, all branch switches closed, I get a deflection of 20 volts. I also get the same reading between the negative side of the service and the system. With the voltmeter connected the same way, and all the branch switches at *B* open, the voltmeter shows 1 volt. When I close the main switch, *D*, and test each branch circuit separately at *B*, six show one volt ground and two show no leakage. The section between *A* and *D* tests free from ground leakage.



INSULATION RESISTANCE PROBLEM.

I should like to ask readers of this journal where the trouble might be located. I have worked on this matter for some time, and have reached no definite conclusion.

Baltimore, Md. ANDREW WESTERVELT.

Mr. Fulton's Dynamo Trouble.

Referring to the "Odd dynamo trouble" described last month by Mr. Fulton, I would say that about two years ago I had a very similar experience with a 10-kw. multipolar direct-current machine. Every conceivable test was made with instruments, and no fault could be located, yet the machine would refuse to generate, and no amount of short-circuiting appeared to affect it. I finally located the trouble, which was a combination of excessive resistance in the carbon brushes and imperfect contact in the brush-holders, which prevented the armature from energizing the shunt field. To remedy the trouble, I substituted brushes of lower resistance, and put a flat spring in each brush holder box. It seems to me Mr. Fulton's mysterious trouble may be accounted for along these lines.

Brantford, Ont. ARTHUR C. LYONS.

In regard to Mr. Fulton's odd dynamo trouble published last month, I would say that when he crossed the two brushes with his screwdriver the short-circuit caused the magnetism of the armature to help the field to pick up. I have used the same method quite often when a machine refused to pick up its field; that is, held a bare copper wire across the brushes. Mr. Fulton would have obtained as good results by disconnecting the shunt field and short-circuiting the machine with only the series coils and armature in circuit. But in doing this, it is well to use a fuse in the circuit to prevent damage. However, it would only make matters worse to short-circuit the terminals with the shunt field in circuit.

Floriston, Cal. F. V. MCAVOY.

I beg to offer the following explanation of Mr. Albert G. Fulton's dynamo trouble: The fact of the machine being compound-wound and not "picking up" when line was short-circuited would indicate that the field magnet had for some reason become reversed, so that residual magnetism in the pole-pieces would tend to send current through the field winding in the wrong direction. The accidental short-circuiting of the brushes by the screwdriver made a circuit of very low resistance independent of the field winding, and caused a very heavy current to flow through the armature, thereby magnetizing the field magnet by induction and causing the machine to immediately pick up the load.

Wilmington, Del. WM. MERRILL.

I read with interest Mr. Fulton's letter last month in regard to his dynamo trouble. It seems as though the only trouble with the dynamo was extremely weak residual magnetism in the field magnets, or else an excess of oil or other lubricant on the commutator. This last cause would be sufficient to keep a low-tension generator from building up on account of the high resistance between the brushes and the commutator. It seems to me as though the dynamo had already begun to generate when short circuited by the screwdriver. It would be impossible for the dynamo to generate if the brushes were short-circuited, because this would also short-circuit the shunt winding. If the leads were short-circuited on the line side of the compound winding then the dynamo might generate a very low e.m.f. by acting as a series dynamo. But, by short-circuiting the brushes, it would be impossible to make the dynamo generate, and for this reason I am inclined to think the machine had already started to "pick up" when short-circuited by the screwdriver.

Ironwood, Mich. CHARLES B. SMEETH.

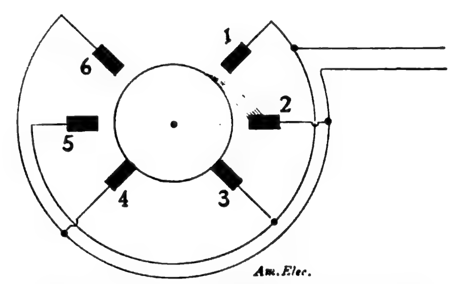
Mr. Anderson's Transformer Trouble.

Concerning the transformer trouble described last month by Mr. Anderson, I would say that when any load is thrown off an alternating-current line, self-induction causes a considerable momentary rise in voltage. This seems to be what happened when the load was taken off one of his transformers, and the rise of voltage caused excessive current to flow in the under-loaded transformer; the greater choking effect of the fully loaded transformer prevented the flow of excessive current in its windings.

Chicago, Ill. H. A. CLARK.

Arcing-over at Commutator Brushes.

During a test of a 6-pole 250-h.p. 500-volt motor, taking a potential curve around the commutator between successive pairs of brushes, a flash-over occurred without any apparent reason. The test was made with the field constantly excited and all brushes lifted from the commutator except the pair between which the test was being made;



ARCING-OVER AT COMMUTATOR BRUSHES.

after taking the curve between one pair of brushes, we put the next group down on the commutator and raised the group of the same polarity that had just been in test. When groups 2 and 3 had been tested (see diagram), group 4 was put down on the commutator and group 2 lifted; as this was done, the machine arced over from group 2 to group 1, which was raised from the commutator. The arc seemed to start between group 2 and the nearest commutator bar, and to spread gradually (relatively so) until it reached No. 1 group of brushes when the circuit-breaker went out. I should judge that the arc took about one second to reach the upper brushes after it had started between No. 2 and the commutator. The change from groups 1 and 2 to groups 2 and 3 was made without any trouble whatever. The armature was of the wave-wound two-path type. I should like to have readers of the AMERICAN ELECTRICIAN suggest what was probably the cause of the trouble.

Schenectady, N. Y. ROBERT E. NOYES.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

The table of breakdown tests of mica plate published on page 31 of the last number of this journal shows that less voltage was required to pierce the thin plates than to pierce the thicker ones; why was this? D. L. G.

The voltages are the volts per centimetre of mica thickness, not the total applied volts

Why are form-wound and separately-insulated armature coils better than winding directly on the core, if the core is properly insulated? D. N.

Because the coils are of equal weight and resistance, and also because they are better insulated from each other than is possible in a core-wound armature. The ventilation is also better.

Why do the negative brushes on a rotary converter become overheated sooner than the positive brushes, with an overload? (2) What is the voltage between collector rings on the three-phase rotaries in the Manhattan sub-stations? M. I. H.

There is no general reason why they should; the cause must be some abnormal condition, which can be ascertained only by test and inspection. (2) 365 volts.

A small single-phase repulsion motor, running with a light load, becomes excessively hot in the armature; what is probably the cause? (2) Would subdividing the turns in the armature coils be advantageous? C. C. R.

The quality of iron in the armature core is poor, or else the discs are burred so as to give a good path for eddy currents parallel to the shaft. (2) Not as to the heating; it would otherwise.

I am running a 12-in. x 18-in. automatic medium-speed engine the valve of which has 3/8-inch lead when the crank is on the center; would not 1/32 or 1/16-inch be more economical? O. W. C.

It might be, but if the lead is the same on both ends it is correct for that particular design of engine, and it is better not to meddle with it. If it is widely different at the other port, adjust the valve-rod to equalize the lead.

Can pipes installed for hot water heating be used for supplying steam radiators? (2) What pressure is required for steam heating? E. W. D. C.

Yes, though they will usually be somewhat larger than necessary, and therefore entail a little more condensation. (2) From 5 to 10 pounds per square inch, according to the character of the service, and the weather conditions.

Can the hypothenuse of a right-angle triangle be determined if only the vertical side and the difference between the base and the hypothenuse are known? K. McL.

Yes: representing the hypothenuse by h, the vertical by v, the base by b and the difference between base and hypothenuse by d, the following relations hold good:

$$\frac{d^2 + v^2}{2d} = h; \quad \text{and} \quad \frac{v^2 - d^2}{2d} = b.$$

Does an incandescent lamp take more current when old than when new? (2) Can a recording watt-hour meter of the type used on three-wire direct-current circuits be used to measure the total power in a three-wire three-phase circuit? E. L.F.

No; it takes more current per candle-power, but the candle-power is much lower than when new. The actual current is less than when new, because the filament wastes away in service and increases its resistance. (2) No.

Will two brine pumps work satisfactorily discharging into a common manifold? (2) What is the relation between current and electrical horse-power in a 2500-volt circuit; what is it in a 125-volt circuit? W. D. W.

Yes; provided the pumps are adjusted to develop substantially equal pressures at their discharge outlets. (2) If the circuits are non-inductive, the electrical horse-power is equal to 3.35 times the current in the 2500-volt circuit and 0.1675 $\times$ the current in the other circuit.

What quantity of resistance wire should be used in series with a theatrical arc lamp supplied from a 110-volt circuit? J. G.

It depends on the current and voltage required by the lamp. Subtract the lamp voltage from the circuit voltage and divide the result by the current the lamp must pass; this gives the total resistance to be put in series. Divide the resistance by 0.005, and the result will be the number of feet of No. 10 galvanized steel wire required; or divide by 0.0074 to find the number of feet of No. 12 steel wire, or by 0.013 to find the number of feet of No. 14 wire.

Why are steadying resistances necessary in series arc lamps? (2) Are they required on series circuits as well as constant-potential circuits? H. J. Y.

Because the resistance of carbon becomes lower when it is heated, and the hotter the arc, the more current will flow at a given voltage, thus increasing the temperature of the arc, and further increasing the current, and so on. The resistance of the steadying coil *increases* with increased temperature, and compensates the tendency of the carbon to draw increased current. (2) Yes; on account of the decrease in voltage at each arc as the carbon becomes heated, the current being maintained constant.

If injectors heat and deliver water to boilers at higher efficiency than pumps and feed-water heaters, why are they not used to the exclusion of the other apparatus? (2) Why are direct-acting steam pumps, taking 100 to 150 lbs. of steam per horse-power per hour, used instead of more efficient pumping engines? W. T. K.

Other factors are involved in practical operation besides mere efficiency, and nearly all of the other factors are favorabde to the pump and heater. It is impracticable to discuss the subject adequately here. (2) Sometimes because the saving would not pay fixed charges on the extra cost of the more efficient pumps; sometimes because the purchaser of the pumps knows no better.

Will an alternator having one damaged field magnet coil cut out of circuit operate properly in parallel with other similar machines having no coils cut out? (2) If the bridged coil is in the armature, will parallel operation be feasible? (3) If one damaged field coil is cut out, should one of opposite polarity to it be cut out also to balance the field? B. H. E.

Yes; but its field strength should be made a trifle greater. (2) Yes; the field should be somewhat stronger to compensate for the reduced armature e.m.f. per unit of field strength. (3) Not necessarily; it might be advisable to cut out the coil diametrically opposite to the damaged and bridged one in order to equalize the radial magnetic pull on the armature core, but it would not probably be urgent to do so.

If railway feeders be re-inforced so as to reduce an excessive drop and thereby increase very greatly the potential at the cars, the bus-bar voltage being unchanged, will the power-house deliver more power to the lines than before on account of the increased speed of the cars? In other words, will the motors take more *current* at the higher speeds than at the lower, for a given controller position? C. J. S.

There would be a slight increase in current per car at any given controller position, and, consequently, a slight increase in the power actually delivered from the bus-bars, but the increase would be far less, proportionately, than the increase in car speed. Most of the increase in the power taken by the cars would be met by the increase in available voltage due to the decrease in line losses.

In some four-pole machines having two brush studs, the brushes rest on the commutator in direct line with the centers of the magnet poles; in others, the brush contacts are in line with the centers of the spaces between neighboring poles; which is correct? H. M. B.

Either arrangement is correct; the arrangement used depends on the way in which the armature leads are carried to the commutator; if one lead of each coil is carried straight out from the slot to the commutator bar in line with that slot, the brushes will be opposite the spaces between poles, but if both coil leads are bent sidewise away from the slots from which they issue and are carried to commutator bars equal distances beyond the axis of the two slots, the brushes will be opposite the pole centers.

What is the difference between long-shunt and short-shunt connections of compound-wound dynamos? (2) What is the difference between the results obtained? (3) What are the relative advantages of waves and lap-wound armatures? C. P.

The shunt-field circuit is connected to the extreme terminals of the machine for "long shunt" and to the brush terminals for "short shunt." (2) There is no important difference practically; with the long-shunt connection the rise of voltage at the shunt-field terminals from no load to full load is a trifle less with the short-shunt connection, which would be advantageous if the difference amounted to anything. Long-shunt connection is preferable to short-shunt, however, where two or more machines are operated at the same voltage because the field of any machine can be excited from the bus-bars when the machine is started up, and its polarity thereby made certain. (3) In a wave winding, each path through the winding passes under every magnet pole, so that the e.m.f. induced in each is the same as that in the others, no matter how irregular the field strengths may be; in a lap winding, each path passes under only two poles, and unequal field strengths induce different e.m.fs. in different paths, making equalizer connections necessary to prevent local currents from flowing in the weaker paths. On the other hand, commutation is more difficult in a wave winding because two or more coils in series are short-circuited at the brushes, and the inductive "kick" is multiplied two or more times.

POWER-HOUSE COAL-HANDLING MACHINERY.

A very interesting and modern equipment of coal-handling machinery is that recently installed in the new power-house of the Philadelphia Electric Company, located

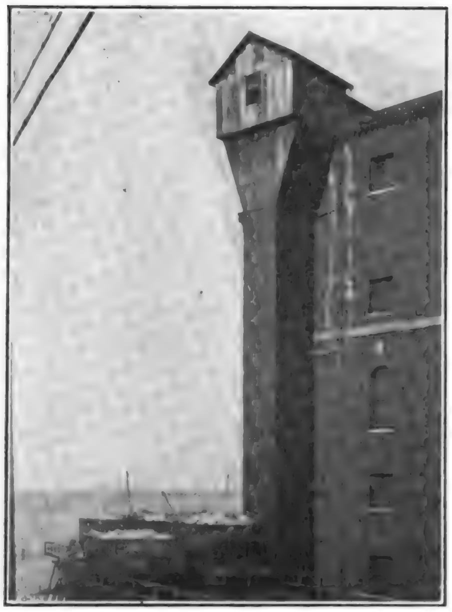


FIG. 1.—STEEL TOWER CONTAINING PATENTED GRAVITY DISCHARGE ELEVATOR AND CONVEYOR.

at Christian Street Wharf, Schuylkill River, Philadelphia, by the Link-Belt Engineering Company, of Philadelphia.

The boiler house, which is a double decked one, stands on low ground adjacent to the Pennsylvania Railroad tracks, and has sufficient floor space to accommodate 16 650-h.p. boilers on each floor. At the present time twelve boilers have been installed on the first floor, nine of which are in use and consume on an average 100 tons of bituminous coal per day of 24 hours.

Coal cars are shifted into the yard on a double track trestle, elevated 27 ft. above the basement of boiler house, at which point they drop their contents into a steel hopper spanning both tracks. This hopper is fitted with a reciprocating feeder, which, it is claimed, controls the delivery of lump anthracite or bituminous with masses 30 ins. and larger in diameter, as readily as it does the delivery of buckwheat coal. This is rendered possible by the fact that the rate of delivery is entirely independent of the size of the discharge opening in the hopper, and that the opening can, therefore, be made large enough to suit the lumps to be handled.

By means of the reciprocating feeder, coal is automatically transferred in uniform quantities and regularly, to an inserted steel tooth crusher, and besides dispensing with the labor of one man at the hopper, to assist and regulate the flow of coal, it prevents overloading the machine and consequent dangers.

The crusher is mounted on a cast iron frame and enclosed by a steel housing. It is made with two charcoal iron, chilled rolls, one of which is mounted in spring bearings, to allow it to yield to a piece of iron or other hard article that may enter the machine. The crusher and feeder are driven by a 15-h.p. motor.

From the crusher coal is spouted to the lower horizontal run of a patent gravity discharge elevator and conveyor, consisting of two strands of forged chain with steel buckets attached at intervals. The vertical run of the machine is supported on foundations by a steel tower sheathed with corrugated iron. (Fig. 1.)

After receiving coal from the crusher, the gravity discharge elevator and conveyor conveys it 30 feet horizontally, then 106 feet vertically, and then 60 feet horizontally directly under the roof of boiler house. A 30-h.p. motor is used for operating this machine.

On the upper horizontal run, coal is discharged into either one of two roller flight conveyors, designed to permit an increase in length when the boiler house is extended. Each of these machines is driven by a 15-h.p. motor, and consists of suspended roller flights attached at intervals to closed joint link-belting. (Fig. 2.) On the conveying run the rollers serve to suspend the flights, so that they will not come in contact with the trough, thus preventing noise and reducing wear to the minimum. The coal is distributed in the 2,000 ton pocket through rack and pinion discharge gates with which the conveyor troughs are fitted.

The coal bunker is equipped with eight chutes, which are arranged to spout the coal in front of the boilers on first and second floors. While this machinery is guaranteed to handle 100 tons per hour, the crusher, it is claimed, easily reduces run-of-mine bituminous coal to about 3 in. cubes, or smaller, at the rate of 130 tons per hour, the elevator and conveyor having capacity to handle the crushed coal at the same rate.

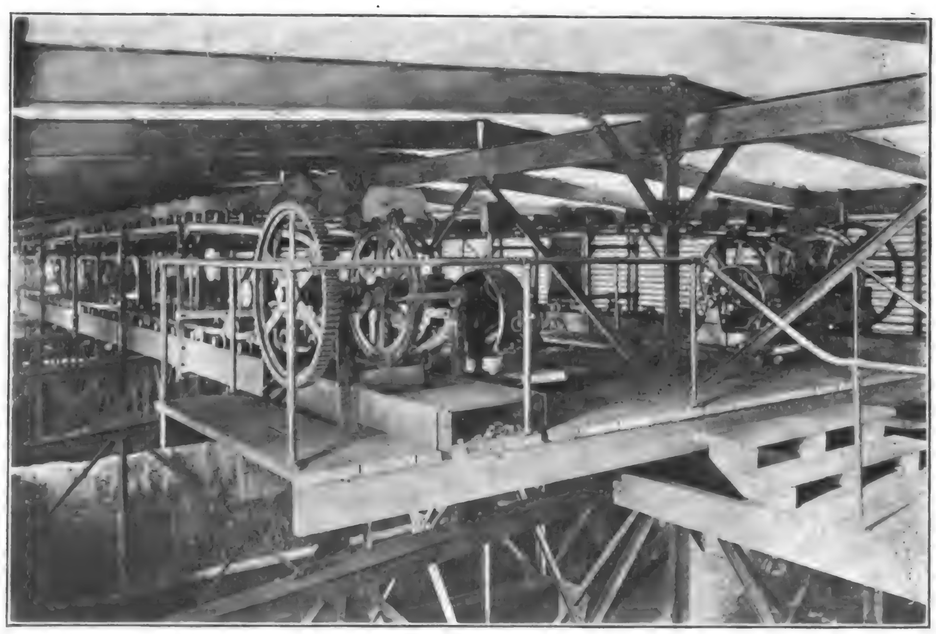

FIG. 2.—DRIVING ENDS OF TWO ROLLER FLIGHT CONVEYORS.

Before the installation of the elevating and conveying machinery, coal was unloaded by a crane equipped with clam-shell bucket, in a pile about 200 yards from the boiler house, and then reloaded by the same crane into trolley cars and carried to the boiler house. This operation required the services of six men every day, whereas the present equipment is said to necessitate the employment of but one man one hour each day to keep the bunker well supplied with coal, and has the further advantage of always having in reserve enough coal to meet all demands of the boilers for twenty days.

THE BOX ELECTRIC ROCK DRILL.

Fig. 1 herewith shows a Box electric rock drill made by the Denver Engineering Works of Denver, Colo., in which many im-

FIG. 1.—BOX ELECTRIC ROCK DRILL.

provements are said to be embodied. Cross-sectional views are given in Fig. 2. The motor designated to be waterproof is shown to the left, mounted on the guides of the shell and coupled to the drill proper by means of machine-cut forged-steel gears. A taper-pin with nut, fastens the motor to the drill and the removal of this pin permits the motor to be removed. It will be noted that the element corresponding to the cross-head of an engine becomes a cylinder in which is fitted the hammer of the drill. This cylinder of cast iron is machine fin-

ished inside and out, and the forged steel hammer is also machine finished all over and fitted to the bore of the cylinder. The form of hammer resembles the piston and rod of a steam engine, leaving an air space between the piston of the hammer and the heads of the cylindrical cross-head. When the drill is in motion the air on each side of the hammer-piston is alternately compressed and rarefied, giving exactly the effect of a spring between the cross-head and hammer. To compensate for possible leakage and to insure a full supply of air, two ports are cut in the side of the moving cylinder, which are so located that as soon as the piston moves from its central position one port is opened to the atmosphere and a supply of air rushes in; then the other port opens and furnishes an air supply to the other side of the piston. Thus, these two ports serve to equalize the air pressure on both sides of the piston as it passes its central position. Oil-grooves are turned in both piston and rod to furnish an oil-packing between the piston and the cylinder walls; also between the rod of the hammer and the cylinder head. Fig. 1 is of a drill with the cover removed in order to show the internal mechanical construction.. The electric current is conducted from the main transmission wires to the controller through heavy rubber-covered mains. The controller is of special design, and includes the necessary resistance for five speeds with proper fuse blocks, all contained in a compact aluminum waterproof case. Connection is made with the drill motor by a short heavy rubber-insulated cable. The motor was designed by the General Electric Company expressly for drill work, and while every means are employed to reduce the size and weight, all precautions are taken for careful insulation and substantial construction. The motor has a waterproof case and aluminum caps are used on the pinion and commutator ends. Suitable hand-holes are provided for inspection and care of the carbon brushes. The motors are wound for 110 or 220 volts, direct current. It would be useless to enumerate the advantages of the electric over other forms of drill. As compared to the air or steam drill the relative advantage in the amount of power consumed is said to be in the ratio of 1.5 to 14.

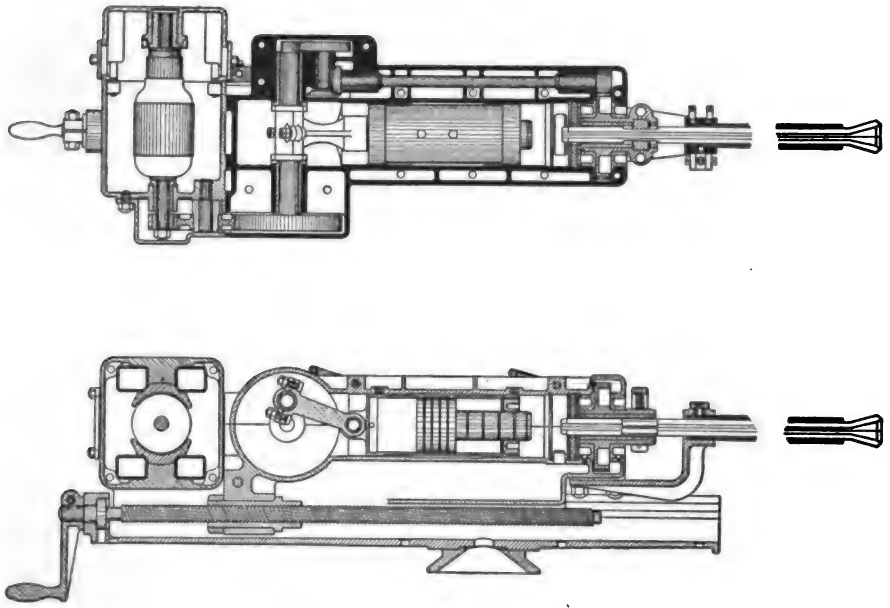

FIG. 2.—SECTIONAL VIEWS OF BOX ROCK DRILL.

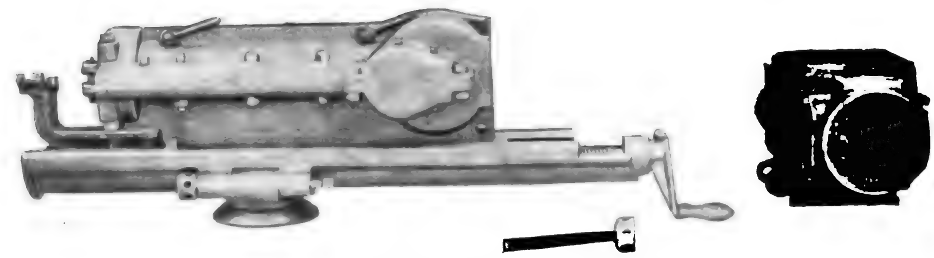

FIG. 4.—BOX DRILL WITH MOTOR REMOVED.

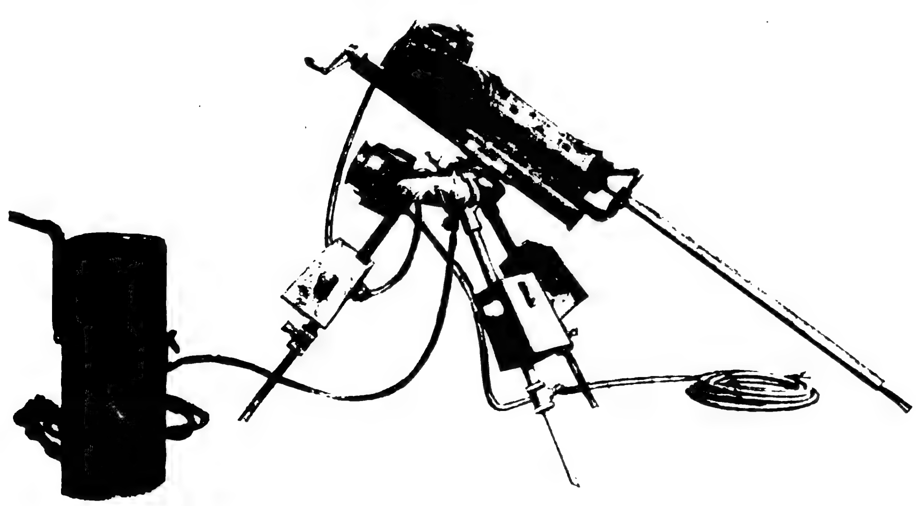

FIG. 3.—BOX ELECTRIC ROCK DRILL.

METHOD OF HEATING AND REGULATING BOILER FEED-WATER.

Among the new problems and opportunities presented by the recent commercial development of the steam turbine is the application of the auxiliary equipment in plants operated by turbines. The Harrison Safety Boiler Works, of Philadelphia, Pa., have paid special attention to the adaptation of their Cochrane heaters to such plants, and have developed some features in these installations which should prove of interest to engineers. The accompanying illustration, Fig. 1, shows an approved method, covered by letters patent, for heating and regulating the boiler feed-water, and is particularly adapted to plants where the steam turbines are operated in connection with surface condensers, although it is also applicable to plants where surface condensers are used in connection with reciprocating engines. 1 is the main steam turbine taking steam through the pipe, *1a*, from the boiler. 2 is the exhaust pipe from the turbine to condenser. 3 is the surface condenser receiving the exhaust from 2. 4 is a pump taking cold water through suction pipe, *4a*, and forcing it through pipe, *4b*, into the condenser. *4c* is the discharge for the circulating water. 5 is an auxiliary engine driving a pump, 6, for drawing the condensation from the condenser and delivering it to the open heater through the pipe, *6a*. *5a* is the exhaust pipe from this auxiliary engine joining the exhaust, *5b* from 4. 7 is a feed-water heater receiving the exhaust from the auxiliaries through the oil separator, 8. 9 is a pump taking the feed-water from the heater through the pipe, 10, and discharging it to the boilers through the pipe, 11. The exhaust from this pump, joining the other auxiliary exhaust, enters the separator, 8. 12 is the supplementary cold-water feed supply emptying into the condenser, 3, to make up any difference between the quantity of condensation and the amount of water required by the boilers. The supplementary water is controlled by the valve, 13, according to the level of the water in the heater, 7. This valve is automatically closed or opened by the float and connecting mechanism. 14 is an air pump exhausting air from the condenser, 3, through the pipe, 15. In cases

where this pump is steam-driven, the exhaust also enters the separator, 8. 16 is the exhaust from the heater to the atmosphere and is provided with a back pressure valve, 17. 18 is an air pipe leading into the condenser and provided with the air valve, 19, for passing to the condenser the air which is liberated from the water by heating it in the heater. By this means the air in the heater is disposed of without permitting the escape of steam. Should there be more exhaust from the auxiliaries than can be condensed in the heater, the pressure increases until it is high enough to open the back pressure valve, 17, and allows the surplus to escape to the atmosphere. It often occurs, however, that the steam from the auxiliaries is insufficient to heat the feed-water to the desired temperature. In order to cover such cases the pipe, 20, is carried to the heater from such a point of expansion in the turbine as will insure the least loss of effectiveness with the greatest potentially for the purpose of making up any possible deficiency in the auxiliary exhaust. In the pipe, 20, is placed an automatic throttling valve, 21, so adjusted that the pressure of the steam when it enters the heater shall be below the pressure at which the back pressure valve, 17, is set. Thus the supply of supplemental steam from the turbine depends upon the pressure in the heater, and is regulated by the needs of the heater itself. The operation of this novel arrangement has important advantages. In addition to all of the condensation of the main exhaust being utilized in the heater, the supplementary cold water is automatically regulated and supplied, and is partially heated in the condenser by the utilization of the latent heat in the main exhaust. All of the exhaust from the auxiliaries is said to be utilized up to the point where they provide more exhaust than is required in the heater, and should the supply fall below the maximum quantity required it is automatically supplemented by steam in the manner already described. The boilers are furnished with water at a uniformly high temperature, there being no sudden fall in the temperature due to variations in the quantity of steam available for heating the water or in the quantity of the supplemental cold water required. The methods by which these desirable results are obtained are claimed to be simple, positive and entirely automatic. It will be seen that in a plant in which this method of heating and regulating the boiler-feed supply is used the auxiliaries are of the independent, steam-driven, non-condensing type. The manner in which the exhaust from these auxiliaries is utilized, however, makes them, it is said, far more economical than the turbine or main engine run condensing, even though the latter may show an efficiency of 15 per cent. or better. If the auxiliaries were run condensing, they could not exceed and probably would not equal this efficiency of 15 per cent., but when operated in the manner described above, their efficiency is very high, for all of the heat in the steam which is not converted into work or accounted for by losses from radiation, etc., is claimed to be utilized in heating the feed-water and turned back into the boilers.

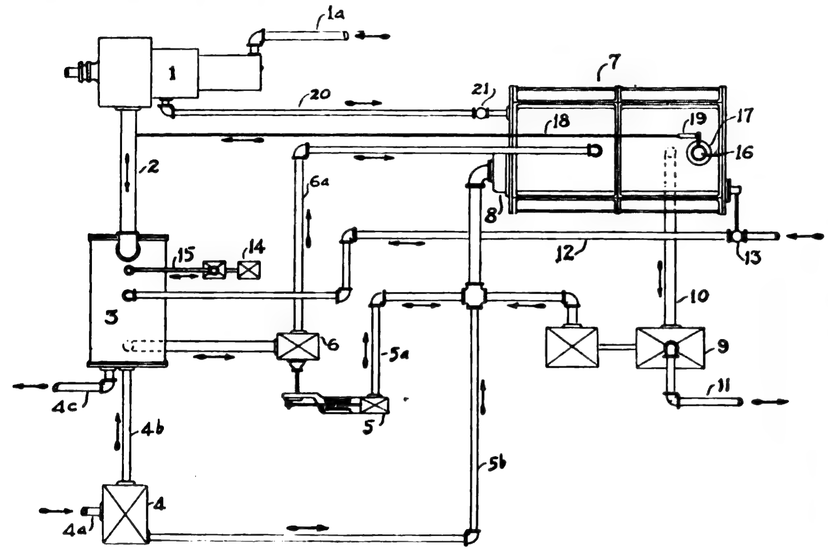

FIG. 1.—SYSTEM OF HEATING AND REGULATING BOILER FEED WATER.

NATIONAL ELECTRICAL CODE STANDARD FUSES.

One of the most important and radical steps in the realm of electrical fittings will be completed April 1, 1905. A universal line of fuses and bases has been adopted by the National Board of Fire Underwriters, and will be the only one approved by that board and allied societies on new work after the above date. All fuses and bases of any given capacity sold by the manufacturers of approved fuses must be interchangeable.

In September, 1903, a joint conference of the Underwriters' Committee, and the leading manufacturers of fuses took up the initial work of securing a national standard fuse, and mapped out a complete line for voltages up to 600, and carrying capacities up to and including 600 amperes. This line was intended to fill all standard requirements within the above limits. Between that time and the present, a great amount of time and money has been expended to determine the exact dimensions and to test fuses made according to the proposed sizes.

FIG. 3.

The first feature to be considered is the style of contacts adopted. They are as follows: (1) Edison or screw plug; (a) 125 volts, (b) 250 volts. (2) Ferrule contact. (3) Knife blade terminal.

The first class includes, under "A," the well-known form of porcelain shell with the brass cover containing a piece of fuse wire soldered to the two terminals. (Fig. 1.)

This fuse is approved on circuits not exceeding 125 volts, in capacities up to and including 30 amperes. For voltages above 125, and not exceeding 250, there is a screw plug type known familiarly to the trade as a "Re-fill." This comprises a porcelain shell containing an enclosed cartridge fuse which may be renewed by a fresh cartridge when the latter is blown. (Fig. 2.)

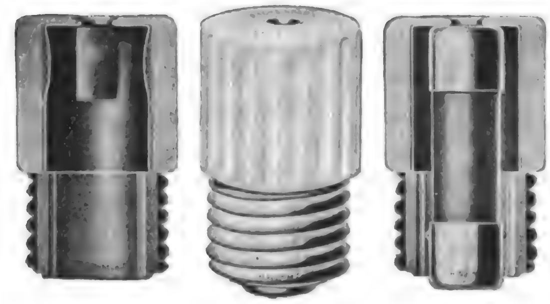

FIG. 2.—NATIONAL STANDARD FUSE PLUG.

Class two, or the ferrule contact cartridge, may be used either in the renewable plug or in spring clips, so formed as to engage a considerable part of the external circumference of the ferrule, and is of the same construction for either place. Fig. 3 shows a standard slate base equipped with spring clips.

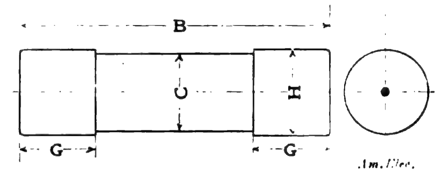

FIG. 5.—0 TO 60-AMPERE CARTRIDGE FUSE.

For all the higher capacities a switch type of contact with a fuse as a knife inserted in one or another form of switch contacts is required. Fig. 4 shows a 400-ampere base and fuse of this type.

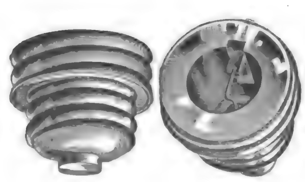

FIG. 1.

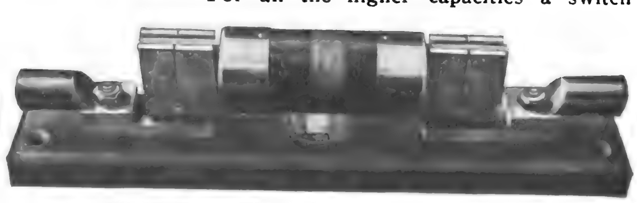

FIG. 4.—400-AMPERE BASE AND FUSE.

The following is a classification with re-

gard to voltage and carrying capacity of the complete line of fuses as described:

0—125 VOLTS.

0—30 amperes, Edison screw plug.

125—250 VOLTS.

3—30 amperes, (Edison screw casing) cartridge fuse, ferrule contact.
31—60 amperes, (spring clips) cartridge fuse, ferrule contact.
61—600 amperes, cartridge fuse, knife blade contact.

251—600 VOLTS.

3—30 amperes, (cartridge fuse) ferrule contact.
31—60 amperes, (spring clips) ferrule contact.
61—400 amperes, cartridge fuse, knife blade contact.

The object sought in a choice of contacts was to secure ease of manipulation in renewing fuses without the aid of tools, and at the same time have sufficient contact to prevent heating. Moreover, it is desired, as far as possible, to prevent improper renewing with any object at hand other than the proper fuse.

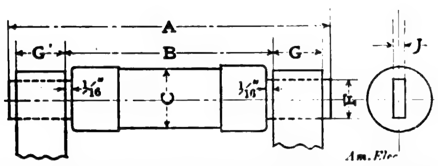

FIG. 6.—61 TO 600-AMPERE CARTRIDGE FUSE.

Next in impoPtance to the style of contacts used is that of detail of construction. The following is a tabulation of the dimensions common to all National Electrical Code standard fuses, the two voltage classifications being distinguished by colors of labels: 250 volts, green; 600 volts, red. The dimensions of the several classes of fuses in the two voltages are made such that no 250-volt fuse can be placed in a 600-base, or one of a given class placed in a base of lower capacity.

250 VOLTS.

Capacity amperes.	B.	C.	G.	H.
0—2				
3—30	2	1/2	1/2	9/16
31—60	3	3/4	3/4	13/16

600 VOLTS.

Capacity amperes.	B.	C.	G.	H.
0—2				
3—30	5	3/4	3/4	13/16
31—60	5 1/2	1	7/8	1 1/16

250 VOLTS.

Capacity amperes.	A.	B.	C.	F.	G.	J.
61—100	6	4	1	3/4	7/8	1/8
101—200	7 1/4	4 1/2	1 1/2	1 1/8	1 1/4	3/16
201—400	8 3/4	5	2	1 5/8	1 3/4	1/4
401—600	10 1/2	6	2 1/2	2	2 1/8	1/4

600 VOLTS.

Capacity amperes.	A.	B.	C.	F.	G.	J.
61—100	8	6	1 1/4	3/4	7/8	1/8
101—200	9 3/4	7	1 3/4	1 1/8	1 1/4	3/16
201—400	11 3/4	8	2 1/2	1 5/8	1 3/4	1/4

All of the knife blade contacts are designed for 70 amperes per square inch of surface contact, this having been found by numerous tests to give a rise of temperature that will not affect, detrimentally, the action of the fuse.

Specifications for enclosed fuses require that all fuses shall carry 10 per cent above their rating under room conditions of 70 to 75° Fahrenheit indefinitely, and that when running normally, shall blow at a current not exceeding 25 per cent above their rating without heating sufficiently to damage the exterior of the fuse. With a current 50 per cent greater than the rating, and at room temperature as before, fuses of the various classes, started cold, must blow within the following specified time:

0— 30 amperes,	30 seconds
31— 60 amperes,	1 minute
61—100 amperes,	2 minutes
101—200 amperes,	4 minutes
201—400 amperes,	8 minutes
401—600 amperes,	10 minutes

All enclosed fuses must be able to stand a short-circuit test, one at a time, when placed on a line having a capacity of at least 300 kilowatts at the voltage for which the fuse is rated, and must not hold an arc, or throw out melted metal or flame to ignite easily inflammable material on or near the fuse.

All the fuses are equipped with indicators which shows at a glance, when the fuse is blown. The ingenuity shown in these indicators is illustrated in the line of fuses manufactured by the Chase-Shawmut Co., of Newburyport, Mass., where a sudden rush of current through an auxiliary or shunt wire of German silver at the blowing of the fuse, heats the wire red hot and fires a powder cap placed adjacent to it, in a small pocket, and ejects a red disc placed in an opening of the tube.

A thoughtful consideration of the requirements of this new line of fuses brings one to the conclusion that a long step ahead has been taken from the old link fuses. The rapid progress in all departments of electrical industry finds no exception in the branch of fuse manufacture, brought to the public notice at this time by the adoption of the National Electrical Code standard fuses and fittings.

TRANSFORMER OUTFITS FOR THAWING PIPES.

The manifest superiority of electricity as a thermal agent in thawing frozen pipes, and the field for this service that awaits development has attracted a considerable amount of attention on the part of central station managers, many of whom have improvised outfits for this purpose. A very general demand for thawing outfits has arisen to meet which the Westinghouse Electric and Manufacturing Company has designed the transformer shown by Fig. 1.

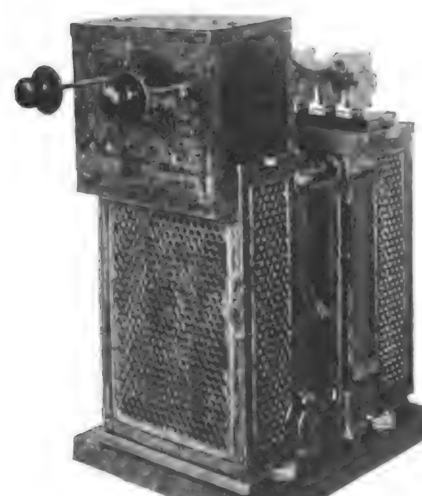

FIG. 1.—TRANSFORMER FOR THAWING PURPOSES.

The outfit weighs complete with transformer, switchboard and base, 750 pounds. It occupies a floor space 2 ft. 4 ins. by 1 ft. 10 ins., and is 1 ft. 7 ins. in height. A link in the top of the transformer case affords a means of lifting the outfit, and if desired truck wheels may be attached to the wooden base. The transformer may be operated satisfactorily on circuits varying from 1800 to 2500 volts. The low tension is arranged to deliver approximately 500 amperes for several hours at an e.m.f. from 15 to 50 volts. By a simple change in connections, the windings may be arranged to deliver about 1000 amperes at voltages from 8 to 16, for thawing large mains whose resistance is generally low. The outfit is suitable for thawing pipes from a ½ in. to a 1 ft. main. The transformer is generously designed, and will deliver large overloads for short periods of time. The windings are air-cooled. The insulation is not injured by rain, snow or ordinary abrasion. There are no moving parts to get out of order, and the entire outfit is contained in a single unit. A light but substantial switchboard is mounted upon the high tension end of the transformer. The switches are of the enclosed plug type, such as are used upon high tension arc light circuits, and permit a variation of the low tension voltage, and consequently the current supplied to the pipes. The company also makes a smaller outfit particularly adapted for thawing service piping about dwelling houses. It is light, of such proportions as to make it easy to handle, and is mounted in a wooden box provided with a handle and shoulder strap. It has a capacity of 200 amperes at potentials up to 25 volts for one hour. It is arranged for operation from a nominal 2000-volt circuit, but can be supplied for any other primary voltage even as low as 200 volts. The voltage regulation and current control are obtained through plug switches in the high-tension circuit. When desired, the outfits are furnished with a current-measuring device, so that the operator may know the amount of current that is being used.

FIG. 2.—TRANSFORMER FOR THAWING PURPOSES.

New Apparatus and Appliances

GENERAL ELECTRIC CEILING SNAP SWITCH.

Fig. 1 herewith shows a new single-pole ceiling snap switch brought out by the General Electric Company. The mechanism of the switch, which is very simple, is operated by pulling a chain attached to the switch, which causes a cam to engage a rachet which in turn operates the switch.

FIG. 1.—G. E. CEILING SNAP SWITCH.

The make and break are positive, the mechanism being similar to the General Electric Company's standard snap switch. The current-carrying parts of the switch are thoroughly insulated from the operating mechanism, and are of sufficient cross-section to prevent excessive heating. The switch is mounted on a porcelain base, and has a nickel-plated cover. It has a carrying capacity of 3 amperes at 220 volts, or 6 amperes at 110 volts.

MERRILL'S TWIN STRAINER.

Fig. 2 herewith shows a twin strainer brought out by G. U. Merrill, of Paterson, N. J., for catching refuse that may be in the water flowing in any pipe, such as the suction to feed or bilge pump or injection pipe to condensers, and permitting the removal of the refuse without interrupting the flow of water. The "Ideal" twin strainer, as it is called, has a cast-iron case, in which are two separate compartments, each containing a perforated sheet brass strainer of ample area for the size of pipe. One of these strainers is always shut off by means of the slide valve shown in the illustration, while the other strainer is performing its work. The valves are fitted with renewable Jenkins' discs. The construction is such that by a half turn of a set screw, the door can be taken off and the strainers removed for cleaning. In operation the device is connected in the suction line and the strainers placed in the case so that the refuse is caught inside the basket or strainer. When one becomes clogged, the valves are run to the other side by means of the hand-wheel, and this automatically closes the clogged strainer and opens the clean one. The cover can then be removed, and the strainer cleaned and replaced ready for use again. The flow of water is not interrupted during this operation, so that the usefulness of the device is apparent.

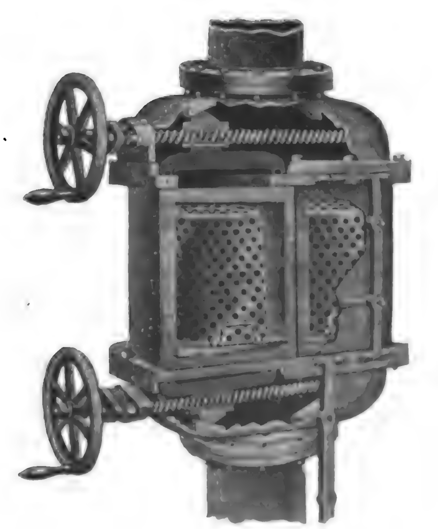

FIG. 2.—MERRILL'S TWIN STRAINER.

NEW EXPERIMENTAL DYNAMO.

Parsell & Weed, New York, have added to their line of small machines for experimental work and amateur construction an interesting little dynamo or motor of the circular yoke type. Figs. 3 and 5 inclusive illustrate the machine and its component parts. The frame is of cast iron, with the poles and yoke-ring cast in one piece; the armature is of the standard laminated and slotted-core type that is used in all commercial machines, drum-wound. The machine is furnished with any of the following windings: 6-volt dynamo for plating, gas engine ignition, etc.; 110-volt dynamo of 110 watts capacity at 1200 r.p.m.; 110-volt dynamo of 220 watts output at 2400 r.p.m.; 110-volt dynamo of 330 watts output at 3600 r.p.m.; dynamotor to reduce from 110 volts to any specified lower voltage, or vice versa. Of course, the machine can be used as a motor at any of the dynamo voltages by putting a starting-box in the armature circuit and taking out the rheostat in the field circuit. The builders sell the complete machine, or the unfinished parts, or the parts finished but unwound, as the purchaser desires. Blueprints and instructions for winding accompany the parts. Other combinations with the same frame will be brought out immediately, such as motor-generators, rectifiers, rotary converters, etc.

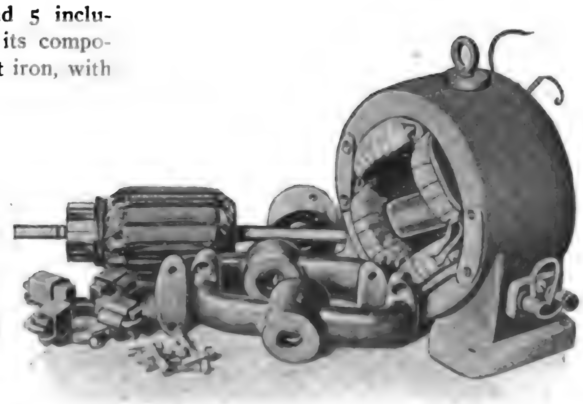

FIG. 3.—NEW EXPERIMENTAL DYNAMO.—Fig. 4.

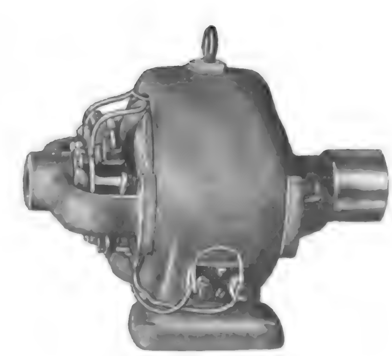

FIG. 5.—NEW EXPERIMENTAL DYNAMO.

ELECTRIC TIME SWITCH.

Fig. 6 shows a time switch marketed by the American Electric Sign Company, of Boston, Mass. The mechanism of this switch is entirely mechanical, the current traversing the switch only. In the upper left-hand corner is a clock movement having two dials, one above the other, the under one of which is calibrated so that every 15 degs. represents an hour. A pin on the front dial engages the front lever which releases the clutch allowing the switch axle to turn through an angle of 90 degs. and close the circuit. A similar arrangement on the back dial engages the back lever which releases a second clutch allowing the switch blades to rotate 90 degs. more and open the circuit. As both dials revolve at the same rate of time all that is necessary to set the switch is to place the pin on the front dial as many hours in advance of the pin on the back dial as one wishes to keep the circuit closed. The cylinder to the left of the switch contains a strong spring, which is wound with a key and which furnishes the power to rotate the switch axle.

FIG. 6.—ELECTRIC TIME SWITCH.

THE BOSWORTH COMMUTATOR FILING DEVICE.

As a means for truing generator commutators which shall be less expensive than turning them down with lathe tools, the Excelsior Machine Works, Akron, Ohio, has placed on the market the device illustrated

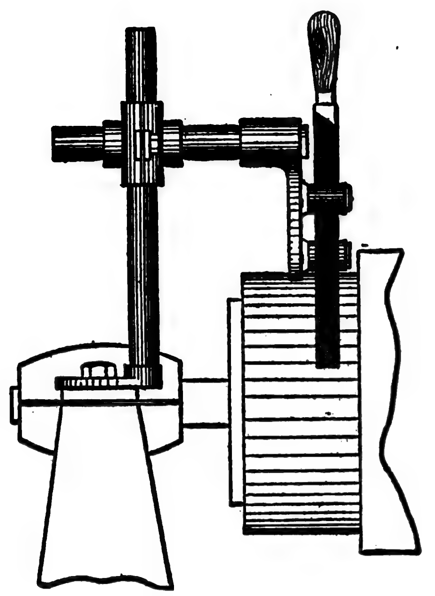

FIG. 7.—COMMUTATOR FILING DEVICE.

herewith. The simple construction and method of attaching it to a generator are shown in the illustration. One of the principal advantages is that no particular skill or previous experience in truing commutators is required to insure satisfactory results. The supporting column for the device is provided with a suitable foot for securely attaching it under one of the cap bolts on the generator bearing. This carries a horizontal bar, which may be

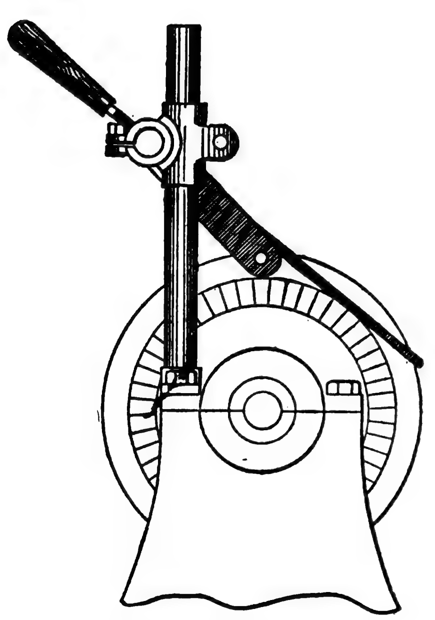

FIG. 8.—COMMUTATOR FILING DEVICE.

clamped at any desired height. The file-holder slides on the horizontal bar, so that the file may be passed across the surface of the commutator. An ordinary file is used, being held in proper position by pins or file rests in the file holder, one of which is slotted and located so as to steady the file and prevent chattering. The file is moved backward and forward over the commutator and, being rigidly secured, cuts to uniform depth, thus not only leveling the surface lengthwise, but restoring the true cylindrical form. As the device is so readily applied, the commutator may be smoothed off as soon as the surface shows the first signs of roughness or unevenness and before it has become sufficiently worn to warrant the removal of the armature or the turning of the commutator by means of a cutting tool. The perpendicular post can be left on the generator at all times if desired, and the horizontal bar can be taken off and put on in a few minutes. The device is applicable to all sizes of generators.

COMBINED BRACKET AND KNOB INSULATOR.

Figs. 9 and 11 show a combination bracket and knob insulator brought out by the Snyder-Hunt Company, of Belle Plaine, Iowa. The fastening screw is passed obliquely through the insulator, so that when once fastened the bracket is prevented

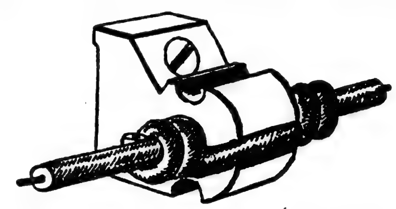

FIG. 9.—SNYDER-HUNT INSULATOR.

from turning. Shoulders on the inner face of the bracket are also provided to secure this result. The knob portion has a transverse bore through which the conductor wire is passed. Grooves are also provided on three sides for fastening wires. While it is intended that the conductor shall pass

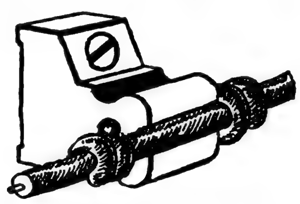

FIG. 10.—SNYDER-HUNT INSULATOR.

through the hole and the fastening wires rest in the grooves, this order may be reversed where it becomes necessary to connect a knob to a wire already in place. With the conductor passing through the insulator, tie wires are not absolutely essential, so that speedy and efficient wiring is

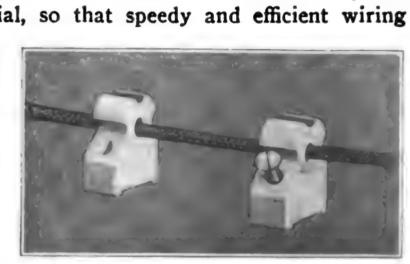

FIG. 11.—SNYDER-HUNT INSULATORS.

possible by the use of the device. Fig. 9 shows the conductor passing through the hole in the knob with the tie wire in the groove, while Fig. 10 shows the conductor in the groove with the tie wire passing through the hole.

TRUMBULL SERVICE BOX.

The Trumbull Electric Manufacturing Company, of Plainville, Conn., has brought out an iron service box for use in cellars or damp places, or where inflammable material is used. The box can, of course, be placed anywhere to enclose a switch and

FIG. 12.—TRUMBULL SERVICE BOX.

cutout so that its applicability is not limited to any particular location. The manufacturers claim that the box is both fire and moisture proof. It is provided with bushings for wire or drilled to take iron pipe conduit. When enclosed fused switches are used in these boxes, the switches are made special as shown. The sizes of boxes range from 8 ins. long and 3 ins. wide to 22 ins. long and 5 9/16 ins. wide. Five sizes of box are built; they are all finished in Venetian black.

TROY AMMETERS AND VOLTMETERS.

The Troy Electrical Company, of Troy, N. Y., are placing on the market a line of switchboard ammeters and voltmeters, one of which is shown by Fig. 13. The working elements consist of a permanent magnet and two stationary coils, together with a pointer and its pivot provided with a small steel vane. The vane is .01 in. thick and ¾ in. in diameter. The instrument is said to be dead beat, a small aluminum damper being provided. The resistance, 3000 ohms for a 125-volt meter, is formed of an alloy

FIG. 13.—TROY VOLTMETER.

having a small heat coefficient. The magnet is made of tungsten steel, the length of steel being over 14 ins. The air gap bridged by the steel vane of the moving element is said to be very short. The company claims that the instrument is very sen-

sitive and has an open scale throughout its length. The scale is said to be more open in those portions most read. The iron base and cover form a magnetic shield so that the instruments are not easily thrown out by stray magnetism in the vicinity.

NEW ELECTRICAL SPECIALTIES.

The accompanying illustrations show several specialties which the Marshall Electric Manufacturing Company, of Boston, Mass., has recently devised and placed on the market. Fig. 15 shows a special angle-wall socket for lighting show windows and other places where incandescent lamps are used with shade-holders. The base of this socket is on an angle, and the shade-holder and shell are made in one piece. They are made both with and without a key, and with a pull mechanism to turn the lamp on and off. Fig. 14 shows a new T. H. locking adapter which, when once screwed into the socket, cannot be readily removed. This is accomplished by a number of spring wings or stops, which bend downward when the adapter is screwed on or forward, but which catch on the porcelain of the socket when turned backward. Fig. 16 shows the new form of snap switch which this company has recently designed. The working mechanism is made of hardened steel, and the mechanical features are decidedly simple. The mechanism consists of a spindle

FIG. 14.

FIG. 17.—GASOLINE SOLDERING IRON AND BLOW TORCH.

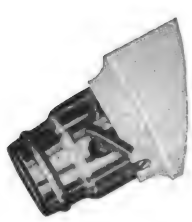

FIG. 15.

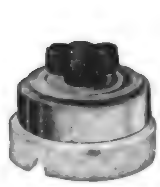

FIG. 16.

with a projecting arm, which fits into a recess in the locking bolt, which, in turn, engages a four-stop ratchet. The springs are of tungsten steel, with phosphor-bronze contacts. The cover—a unique feature of this switch—is lined by a cup of "Elastoid" fibre made in one piece, without wrinkles or seams. The handle is claimed by the maker to be unbreakable. The bases are made both for open and concealed work.

SOLDERING IRON AND BLOW TORCH.

Emmelmann Brothers Manufacturing Company, of Indianapolis, Ind., are introducing a patent combination automatic gasoline soldering iron and blow torch illustrated in Fig. 17, which is one-third the actual size of the tool. The method of operation is as follows: The cap, *A*, is removed and the magazine filled with gasoline within ½ inch of being full; then the cap is screwed on firmly. The alcohol lamp which accompanies each tool, is lighted and the iron is heated at *B* for at least three minutes in a slanting position with the head down, keeping the valve, *C*, closed to generate a hot gas pressure. After heating *B*, the valve, *C*, is gently opened and lighted by passing the tool over the flame at *F*. The tool should continue to be heated at *B* for three minutes more. The operator can regulate the blast to suit the work to be done by means of valve *C*. If the work is being done outside in a heavy wind, or the tool is used as a blow torch, the shutter at *B* should be closed. The soldering copper is universal. Any shape copper point can be used. By removing the copper point shown at *E*, the tool can be used as a blow torch. The tool is furnished with two drop forge coppers; one for regular work and one for heavy work. The head is a high-grade steel casting. The cylinder is made of 16-gauge drawn brass tubing, threaded at both ends. The joints are tinned and sweated, and blunt brass valve stem is used.

GUTHRIE SIGN FLASHER.

Fig. 18 shows the Guthrie sign flasher made by William A. Corrao & Company, of St. Louis, Mo. The flasher is enclosed in an iron box 8 x 5 x 5 ins. and arranged so that it can be readily attached to the wall. The box is lined with ½-in. slate in rear and top. The binding posts are located on the top so that it is not necessary to open the flasher to install it. The flasher is operated by an extra heavy special spring motor, which runs from ten to twelve hours with one winding. All contacts are of platinum and the switches are rated at 6 amperes per switch. All working parts, binding posts, etc., are of brass. A diagram of connections accompanies each flasher.

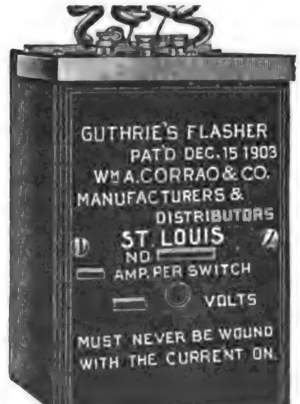

FIG. 18.—SIGN FLASHER.

OTIS FEED-WATER HEATER, OIL SEPARATOR AND FILTER COMBINED.

The accompanying illustration shows the Otis feed-water heater, oil separator and filter combined built by the Stewart Heater Company, of Buffalo, N. Y. This heater consists of a steel shell with cast-iron heads, sustained by four cast-iron legs bolted to the conical bottom, thus making a substantial base for the heater. The exhaust steam enters the heater at the side and passes directly into and through the oil separator, where the oil that is carried over with the exhaust steam from the engine cylinder is separated and passes out at the bottom of the oil separator through the oil discharge pipe. The exhaust steam then passes on into the mingling chamber, where it is brought into direct contact with the spray of cold water, and as the spray of cold water and exhaust steam cannot separate until they both pass out at the bottom of the mingling chamber together, the water is heated almost as hot as the exhaust steam. The exhaust steam then circulates freely through the steam space and passes out at the opening on top. This steam can be used for other heating purposes, if required, as all the water of condensation is said to be deposited in the heater. The feed-water pipe enters the side of shell, turns upward and projects into the mingling chamber, where it terminates in a conical spray nozzle. The spray of water is thus brought into direct contact with the

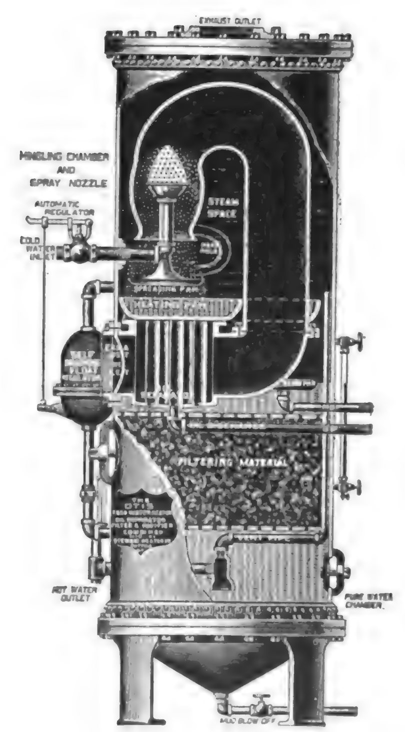

FIG. 19.—OTIS FEED-WATER HEATER AND FILTER.

exhaust steam as it enters the heater, and becomes instantly heated; the heated water then falls upon the spreading cone, where it is again sprayed or spread into the heating pan and flows over its edges before it can mingle with the water in the heater. The heated water is then in the proper condition to deposit the impurities, and as it passes down through the filter or filtering chamber, the clay, sand and other matter in suspension, the carbonate of lime and magnesia in solution, are separated, and the pure water enters the pure-water chamber, which is of large capacity, to allow any particles of sediment that may be in the water to settle in the bottom, where it can be blown out at any time by opening the blow-off valve. The supply of water to the heater is automatically controlled by the float and regulating valve, which keep the water at the proper level in the heater at all times. The float is self-draining or unsinkable, the stem being a brass tube, so should there be any leak, the water could pass off through the stem and the float retain its buoyancy. These floats are made of copper, and are tested to 200 pounds. The float is placed in a separate chamber, attached to the heater shell at the top and bottom, so that any variation in the water level in the heater will cause the float to rise or fall, thus opening or closing the regulating valve, and keeping just the proper amount of water in the heater. The automatic regulating valve is balanced, and is operated with a very slight movement of the float. The filtering chamber is easy of access, and the filtering material can be removed when necessary, and the chamber refilled in a few minutes. None of the scum or oil can get into the boilers, as the pure water is taken from the center of the water chamber, and the hot water or suction pipe to the pump is furnished with a vent pipe, so that should the supply of water be shut off and lower the water in the heater, the pump would stop pumping.

ANDERS PUSH-BUTTON TELEPHONE.

The accompanying illustration shows the various parts of the Anders push-button telephone made by the Edmonstone Company, of New York City. From left to right the parts are as follows: (1) fiber plate for wires to pass through before connecting to metal lugs on telephone; (2) transmitter-base switch, etc.; (3) receiver cap; (4) receiver diaphragm; (5) receiver base, etc.; (6) button cap; (7) button. The receiver is of the watch-case type and is fitted with a bipolar compound magnet. The magnet, pole-pieces, binding posts, etc., are cast solid in hard rubber composition shells so that the adjustment of the pole pieces to the diaphragm is assured. The coils are wound with silk-covered magnet wire over split bobbins, then placed over the pole pieces and held in place by a small nickel cap. This arrangement allows the coils to be changed in case of accident. The back of the receiver shell is fitted with a receptacle for the calling springs and button. A cap is screwed over the receptacle which holds the button in proper relation to the springs which are made of German silver and secured to metal lugs cast in the back of the receiver shell. The transmitter movement is of the solid back type, with self-contained granular carbon and electrode holder of the button type, having a metal diaphragm secured to the front electrode of the button. The base of the transmitter is fitted with an automatic switch, provided with pin-point springs. In the hard rubber composition base are cast metal lugs fitted with machine screws and washers threaded into the lugs for the transmitter and receiver cord, switch and spring connections, also for the bell, line and battery connections, the base being formed and cast as in the case of the receiver. On the face of the transmitter base is a nickel finished metal plate with two ear lugs, to engage the grooved metal ring, which is cast over the receiver cap, holding the receiver in place when same is not in use. The placing of the receiver in the ear lugs engages the lever of the automatic switch, which in turn changes the circuit springs on the back of transmitter base, cutting out the transmitting and receiving circuits, and cutting in the signal bell circuit. There is a small fibre disk fitted in the back of each transmitter base, which disk has a number of holes that correspond to the lugs in the base to which the various wires are to be connected. The disk is also for protection of the transmitter button, switch, spring connections, etc., and when in place (after the wires are connected) rests on a small inverted rim. The disk is further supported by four small posts, one on each side of transmitter button and one on each side of the switch springs, in back of the transmitter base. The following are the dimensions of complete telephone over all, consisting of transmitter, receiver and connecting lugs: diameter, 3½"; depth, 2¼"; depth of telephone over all, mounted on intercommunicating switch block of the wall type is, 3¼". The telephones for all systems are identical as to outward appearance, construction and material used and are wired and fitted for the following systems: straight line, intercommunicating, switchboard or return call annunciator, central station and selective ringing common battery systems. Complete wiring diagrams, showing connections of the systems, accompanying each instrument.

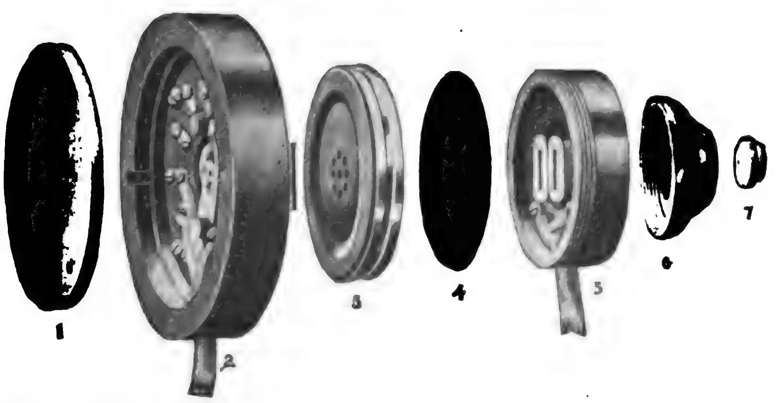

FIG. 20.—TRANSMITTER AND RECEIVER OF ANDERS PUSH BUTTON TELEPHONE.

SANGAMO WATT-HOUR METERS FOR DIRECT CURRENT.

Fig. 21 herewith illustrates the new Sangamo watt-hour meter made by the Sangamo Electric Company, of Springfield, Ill.

FIG. 21.—SANGAMO WATT-HOUR METER.

The rotating element of this meter, which is of the mercury contact type, is a heavy copper disc immersed in mercury and enclosed in a box of specially formed insulating material which is said to be both hard

FIG. 22.—SANGAMO WATT-HOUR METER.

and durable. In the walls of this chamber are embedded copper contact ears shown in Figs. 21 and 23 and connected outside by knurled adjusting nuts to flexible cables carrying the main current. Two powerful

magnetic fields cause rotation of the disc. The fields are due to two soft iron poles embedded in the lower half of the disc chamber wall, and energized by the series and shunt coils. These same fields are also used as damping magnets to govern the speed of the meter, so that no permanent magnets are used. To overcome in a measure the buoyant effect of the mercury of the disc, a counterweight is attached to the disc shaft in an upper part of the insulating casing. This weight being a trifle less than the buoyant effect of the mercury permits of a slight thrust against the jewel in the upper bearing of the meter. This bearing

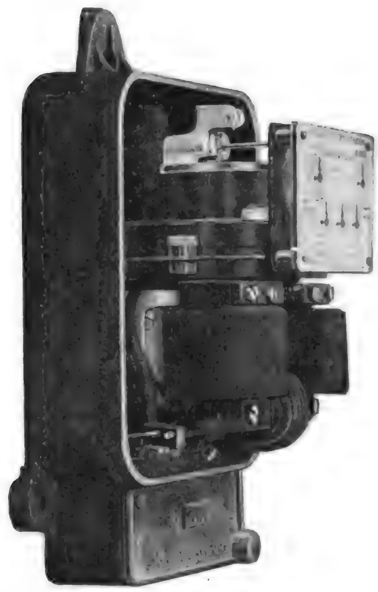

FIG. 23.—SANGAMO WATT-HOUR METER.

carries a flat jewel, and has a fine screw adjustment to give the disc just the contact pressure desired. When the adjustment is complete, the bearing is held in position by a small screw. Owing to the strong field and small air gaps, external magnetism is said to have no effect on the meter. An iron return plate above the disc and the iron back of the meter also act as an effective shield. The meter is sealed in the case after being tested, and need not be removed, as the mercury is shipped in the disc box and the spilling of it is prevented by the design of the opening through which the disc shaft passes to the outer upper bearing. A pocket is provided, into which the mercury flows when the meter is turned over, and when the meter is placed upright and in position, the mercury returns to its proper place. The meter is adjusted by sliding the connecting nuts back and forth on the copper disc box ears, thus altering the distribution of current through two paths in the disc having different torque effects. The light load adjustment is very simple and may be easily made. A high resistance rod, shown below the shunt magnet in Fig. 22, has a sliding connector on it which is in contact with the ingoing shunt wire. By altering the position of this wire along the rod, the small current passing to the shunt coils is divided between two paths, one through the disc and back to the connector through the right end of the rod, and the other directly from the in post through the left end of the rod. That portion of the current passing through the disc tends to produce some rotative effect, and this effect is varied by moving the sliding connector from the left to right of the resistance rod. The meter is 9 ins. high, 5½ ins. wide, and projects 4¾ ins. when installed. The case may be of aluminum or glass, the meter with the former covering weighing 10 lbs. For 110 and 220-volt maters, all resistances are placed in the case; for 500-volt meters the resistance tubes are placed in a small perforated cast-iron box, which may be placed near the meter. All meters up to 40 kilowatts capacity read directly in watt-hours; larger sizes require a multiplier.

NEW VARIABLE SPEED MOTOR.

The Crocker-Wheeler Company, of Ampere, N. J., has brought out a new line of variable speed motors, one of which, with its controller and resistance, is shown by Fig. 24 herewith. The line is complete for single voltage circuits of 115 and 230 volts, and the speed variation is obtained by field regulation alone. The general design of these motors is such as to adapt them readily to machine tool application. The bearings are of the ring oiling type, thoroughly protected from the intrusion of dust and dirt. The pole pieces are of cast steel to which are fastened pole shoes holding the field coils in place. The coils are carefully wound and insulated, the outer surface being covered with stout insulation coated with varnish as a protection against dirt and dampness. These motors are arranged in two classes, the first being adapted to give constant horse-power throughout a speed range of 2:1, and the second being arranged to give a constant horse-power throughout a speed range of 3:1. Both of these classes are designed for operation on a single voltage of either 115 or 230 volts. In order to adapt these motors more thoroughly to the requirements of the machine tool builders, the classes are divided into two groups, the group comprising the smaller sizes of motors being designed to operate at a maximum speed of 1600 r.p.m., and the group comprising the larger sizes at a maximum speed of 1400 r.p.m. These speeds have been selected as being the highest at which it is considered good practice for the motors to operate. The advantage of having the motors thus grouped as regards speed ranges will readily be appreciated by the tool builders, as they are thus afforded a choice in the power of the motor which may be applied to a given tool without the necessity of altering their speed mechanisms to suit the varying speeds which are usually involved in a change of motors. For use with these motors full reverse controllers of the drum type are usually supplied, which are used for starting the motors and for weakening the fields up to maximum speed. The company states that in putting this variable speed motor on the market it is in no way disloyal to its multiple-voltage system which has become thoroughly established; but in certain classes of equipment the installation of the multiple-voltage system is often not warranted.

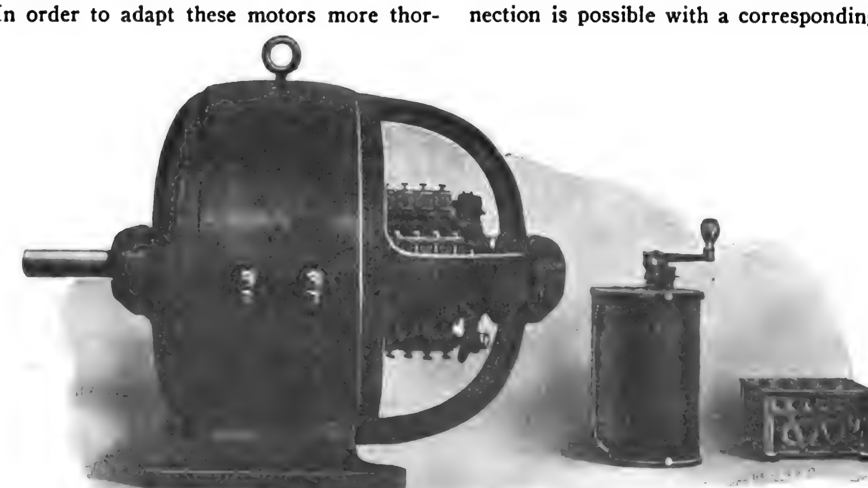

FIG. 24.—CROCKER-WHEELER VARIABLE-SPEED MOTOR.

DOSSERT TERMINALS.

The principle of the Dossert joint can be applied to any device for making electrical connections. In places where lugs for soldered joints are now used, the regular

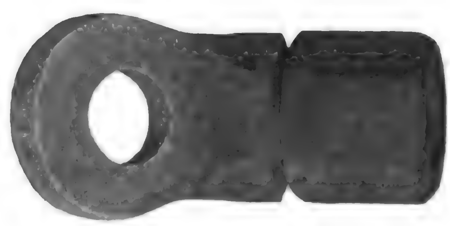

FIG. 25.—DOSSERT BENT LUG.

Dossert nipple and nut are ready substitutes, these being used in place of the ordinary receptacle into which the cable is soldered. As is probably well known, no solder is used in the Dossert joint, so that a great reduction in the time required to make the connection is possible with a corresponding reduction in cost. For example, the manufacturers state that a Dossert joint connection for a 1,000,000 cir. mil cable can be made by one man in seven minutes, which is evidently a much shorter time than would be required to make the soldered connection. The gain in this respect is, of course, greatest with the largest cables. Fig. 25 shows

a Dossert bent lug designed for special switchboard connection. The joint will accommodate a 1,000,000 cir. mil cable. Lugs of this type have been installed in one of the large public buildings of New York City. Figs. 26 and 27 show the assembly and one of the parts of a lug designed for

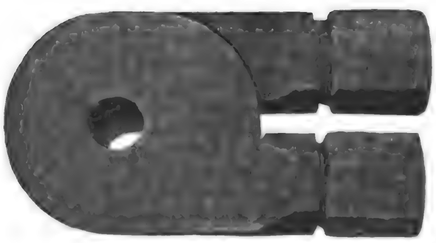

FIG. 26.—DOSSERT TWIN LUG.

one of the generators being installed in another large public building in this city. The lug is made in two parts to permit a swivelling motion about the centre bolt in order to line up the connections with the incoming cables. The combined carrying capacity of the cables is about 1200 amperes. It might be interesting to note that at the recent meeting of the National Board of Fire

FIG. 27.—PART OF TWIN LUG.

Underwriters, held in New York, the Dossert joint received favorable consideration. Its use was not approved unqualifiedly, since the opinion was expressed that the behavior of the joint in the field of everyday practice, where it would be subjected to all kinds of conditions and abuse, should first be ascertained. In order to obtain this information permission had, of course, to be given for its use. This permission is subject to the discretion of the local Boards of Fire Underwriters, who, before giving it, must be informed just where the joints are to be used. The devices are made by Dossert & Company, of New York City.

ATLAS WATER-TUBE BOILER.

The American water-tube boilers recently purchased by the Japanese Government for use in reconstructing the docks at Port Arthur, are of a new type, differing very radically in many particulars from the older types of water-tube boilers. The boiler is composed of a nest of tubes, set on the ordinary incline between water legs, and three drums running across the tubes instead of lengthwise at the top. The front and rear drums, together with their water legs, are each made of two plates, riveted at the top of the drum and at the bottom of the leg. This method of construction enables the builders to eliminate seams next to the fire or hot gases, since the only seam in each of these legs is at the bottom, where it is protected by the masonry, while the seams of the drums are located on the top, away from the fire. This method also gives a full length opening at the throat, where the water passes between the leg and drum. The throat is braced with a patent twisted brace which leaves over 80 per cent of the area open. The rear drum contains a mud pan through which the feed-water flows and where practically all the impurities of the water are said to be precipitated. A connection from the bottom of the pan through the drum head permits the precipitation to be blown out. This mud pan or purifier is built in sections and can be removed through the manhole and renewed at small expense when it becomes pitted. The mud pan occupies small space and there is considerable generating surface in this rear drum. The fresh water from the purifier flows down through the rear leg and up through the tubes and front leg to the front drums, where there is a large releasing surface. The two drums are connected by straight equalizing tubes, arranged in three tiers along the ordinary water line. Each of these drums is connected with a middle drum by tubes and the steam as it is released, travels through these tubes to the middle drum, from which it is taken for use. The builder states that experience has shown that by thus carrying the steam to a third drum through tubes exposed to the furnace gases, not only is perfectly dry steam obtained, but this steam is given superheat, varying from 10 to 22 degrees, according to the state of the fire. Since all the tubes carrying water are straight and readily accessible, the boiler is easily cleaned. The boiler is built by the Atlas Engine Works, Indianapolis, Ind.

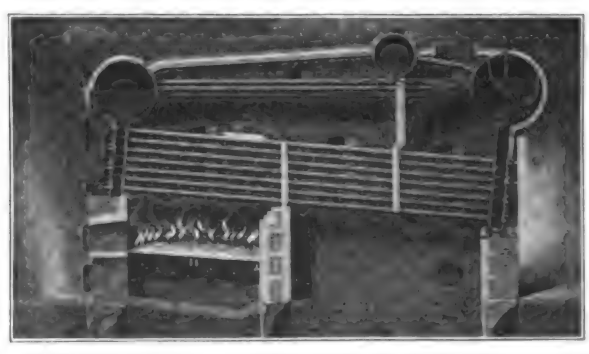

FIG. 29.—ATLAS WATER-TUBE BOILER.

CARPENTER'S NEW FULL MOUNTED DIE STOCKS.

Fig. 28 herewith shows a new full mounted set of dies and taps made by the J. M. Carpenter Tap & Die Company, of Pawtucket, R. I. Each assortment has a stock

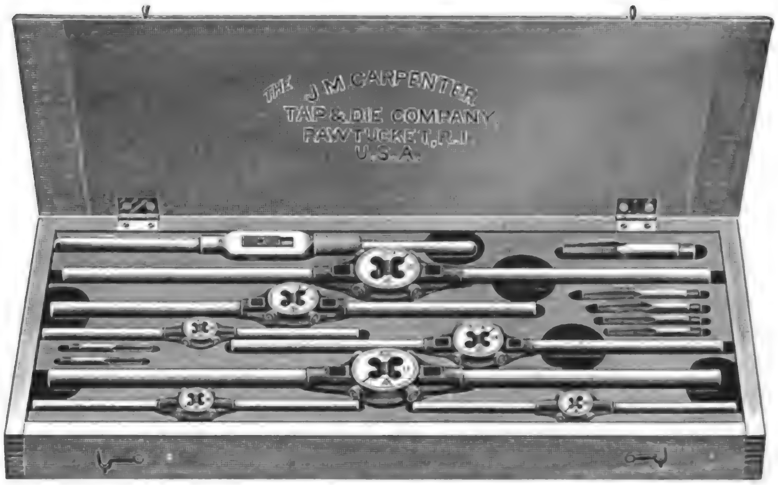

FIG. 28.—SET OF FULL MOUNTED DIES AND TAPS.

for each die and Nichols' adjustable tap wrenches for holding all sizes of taps contained in assortment. The set is put up in a hardwood case as shown. The set shown is known as No. 80. It is made up in three styles; one set containing V thread standard sizes; another, rough iron sizes, and the third, U. S. standard thread sizes. The company, of course, make any kind of combination desired. The contents of each No. 80 set is as follows: V Standard sizes.—Cutting, 1/4 x 20, 5/16 x 18, 3/8 x 16, 7/16 x 14, 1/2 x 12, 5/8 x 11, 3/4 x 10, with a No. 1 Nichols' patent tap wrench and a stock for each die. Rough Iron Sizes.—Cutting, 9/32 x 20, 11/32 x 18, 13/32 x 16, 15/32 x 14, 17/32 x 12, 21/32 x 11, 25/32 x 10, with a No. 1 Nichols' patent tap wrench and a stock for each die. United States Standard.—Cutting, 1/4 x 20, 5/16 x 18, 3/8 x 16, 7/16 x 14, 1/2 x 13, 5/8 x 11, 3/4 x 10, with a No. 1 Nichols' patent tap wrench and a stock for each die.

PORTABLE WATT-HOUR METER CALIBRATORS.

The Ft. Wayne Electric Works, Ft. Wayne, Ind., have brought out a ringing and a registering watt-hour meter calibrator for use in calibrating watt-hour meters

FIG. 30.—REGISTERING CALIBRATOR.

without removing them from service and without expending more than a few minutes in their calibration. The ringing calibrator is shown by Fig. 31 herewith. A standard "Type K" watt-hour meter of proper capacity, voltage and frequency, but without the recording mechanism is mounted on the inside of a wooden carrying case. The case is provided with leveling screws and a small spirit level set into the base. In the case is also a double-pole double-throw switch by means of which the series coils of the standard can be connected either in multiple or in series for double or normal rated current. This prepares the calibrator for use with 5 and 10

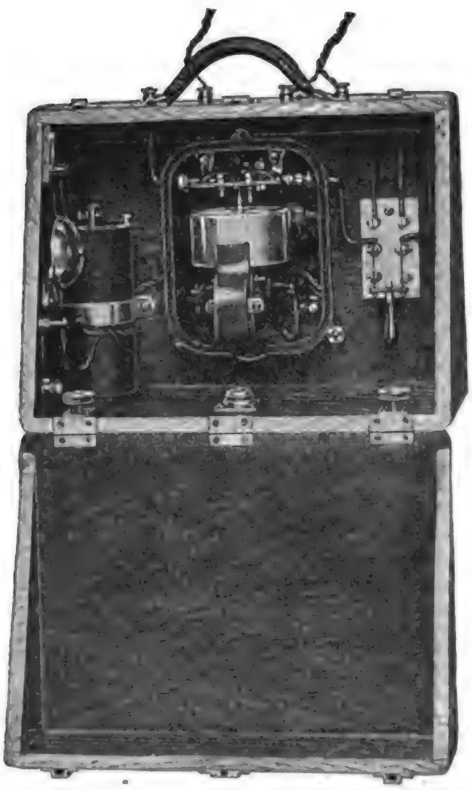

FIG. 31.—RINGING CALIBRATOR.

ampere meters by direct comparison without a speed constant, the change in connections making no change in total ampere turns or speed. The scope of the calibrator is further magnified by using a speed constant of 2 for calibrating 15, 20 and 25-ampere "Type K" meters. For comparing the speeds of the two meters, a bell circuit is connected with the standard through a two-segment commutator on its armature shaft in place of the registering train. At every revolution of the standard armature the bell circuit is closed through a dry battery mounted on the left side of the case. This bell circuit may be permanently opened when not in use by a two-point switch. The dimensions of the case are 15 by 11 by 8 ins. The registering calibrator shown in Fig. 30 consists of a "Type K" meter, having the regular registering train replaced by a double reduction train and two dials instead of five. The dials register revolutions instead of kilowatt-hours. This is a much simpler device than the ringing calibrator, but is much more restricted in its adaptability. Two adjustng screws are provided on the bottom of the frame for leveling it for use, the third support being on the bottom of the case. The jewel bearing screw is extra long, and projects through the case at the bottom so that the shaft can be raised or lowered without removing the case which can be sealed and the adjustment of the standard protected from outside disturbances. The calibrator terminals can be reached by removing the terminal cap. The dials of the calibrator will register 110 revolutions, which is equivalent to nearly three minutes' running at full load. If the revolutions of the meter to be tested be counted and compared with the difference in calibrator readings before and after counting an exact oomparison of speeds is obtained.

SUCCESSFUL DEVELOPMENT FROM AN UNPRETENTIOUS START.

In the year 1874, Mr. J. D. Cox, in a very modest way, established himself in Cleveland, for the manufacturing of tools. Five years later, Mr. F. F. Prentiss joined him as partner. For twenty-five years this partnership went on uninterrupted and was known to the business world as "Cleveland Twist Drill Company." During this period, by careful management and under the constant ambition to produce tools of the highest quality, the business prospered, until to-day its product is found wherever machinery is built. The immense factory, built up as increased business demanded, and equipped with special and modern machinery and appliances, further attests the result of successful business methods.

After thirty years of constant activity, Mr. Cox has decided that he has earned a little rest and relief from responsibility, which decision was strengthened by health considerations, and with this in view, the parnership was merged into a stock company on December 31, 1904, under the name of the Cleveland Twist Drill Company. Before transferring the partnership affairs to the stock company, several of the old employees were invited to take stock, and this opportunity was readily accepted by all to whom the privilege was accorded.

While Mr. Cox will be relieved of active duties, he will retain his large holdings in the business, and also serve in the capacity of vice-president and director. The other officers of the company are: F. F. Prentiss, president and general manager; E. G. Buckwell, secretary, and George F. Kast, treasurer. Notwithstanding that this change has taken place, the personnel of the company remains intact, and the business and manufacturing policies of the past will be maintained in the future.

FORT WAYNE ELECTRIC WORKS CONVENTION.

The Fort Wayne Electric Works is one of the oldest concerns in this country now engaged in the manufacture of electric lighting and power apparatus. It is probably best known as the manufacturer of the "Wood" systems of electric lighting and power which may be found in use in many plants in this country.

The extent of territory covered by the sales organization reaches from Boston to San Francisco, and from St. Paul to Atlanta. The modern methods of the company are well illustrated by the periodical conventions of the district managers of the various sales territories and the home office organization. The last convention was held from January 10 to 13, of this year; the daily business sessions of the convention were relieved by evening social functions of a very enjoyable nature. Representatives from Boston, New York, Philadelphia, Syracuse, Pittsburg, Atlanta, Cincinnati, Grand Rapids, Chicago, St. Paul and St. Louis were present.

The closing feature of the convention was a banquet at the Anthony Wayne Club, at which over fifty of the sales force were present. The banquet was presided over by Judge R. S. Taylor, who has been counsel for the company since its infancy. Guests from the city included the local directors and others interested in local electrical organizations.

During the evening the district managers, as an expression of their appreciation and esteem for the one who is responsible for the products they handle, presented Mr. J. J. Wood with a handsome loving cup through their spokesman, Mr. W. S. Goll, manager of the Chicago office. Mr. Wood has been with the Fort Wayne Company since 1890, when he went to Fort Wayne from Brooklyn, when the Fort Wayne Company purchased the Brooklyn plant, then manufacturing Mr. Wood's arc lighting apparatus. He immediately assumed charge of designing new electrical apparatus and redesigning the old apparatus and electrical devices already in production by the company. That Fort Wayne apparatus is now in such extensive use is due primarily to the high degree of Mr. Wood's ability as a designer. It was in recognition of this that the district managers of the company presented him with the loving cup.

THE AUTOMOBILE SHOW.

The fifth annual automobile show, held January 14-21 last, at Madison Square Garden, was by far the most successful one that has thus far been held. Every available square foot of the enormous space was occupied, and the indications were that a much larger exhibition hall could have been filled. The exhibition was noteworthy for solid improvement in construction and a far smaller proportion of freaks than has been the case in previous years. The French type of vehicle predominated largely, and a very great improvement in the touring car style is noticeable in the use of side-opening doors to the rear compartment instead of the dangerous and inconvenient door at the extreme rear of the car, which has been heretofore universally employed. The use of a side door, of course, involves the use of a longer wheel-base, and in most cases the means of entrance to both the front and rear seats consists of a broad running board or platform instead of the usual restricted individual steps.

Among the gasoline cars, the four-cylinder type was by far the favorite; in this exhibition there were about 130 cars of this type and less than one-tenth this number of the two-cylinder type, and there were still fewer of the other types. It is also noteworthy that the two-passenger runabout form of vehicle, which was so popular last year and previously, appears to be losing ground. The large majority of vehicles in the present exhibition were for four or more passengers. The number of electric vehicles was relatively small in comparison with the gasoline type, which is, of course, natural, in view of the limited radius of action of the electrical type. Only six companies exhibited electrical vehicles, namely: The Vehicle Equipment Company, the Studebaker Automobile Company, the Electric Vehicle Company, the Baker Motor Vehicle Company, the Pope Motor Car Company, and the National Motor Vehicle Company.

There were, of course, a number of exhibits of electrical auxiliaries, such as induction coils, batteries, ignition dynamos, spark plugs, etc. Among the exhibitors of these specialties were: the American Coil Company, Somerville, Mass.; American Electrical Novelty & Manufacturing Company, New York; Atwater Kent Manufacturing Company, Philadelphia; Auto-Coil Company, Jersey City; Constant-Spark Plug Company, Boston; Crest Manufacturing Company, Dorchester, Mass.; Dayton Electrical Manufacturing Company, Dayton, Ohio; Dow Portable Electric Company, Braintree, Mass.; Eastern Carbon Works, Jersey City; Electric Contract Company, New York; Motsinger Device Manufacturing Company, Pendleton, Ind.; National Carbon Company, Cleveland, Ohio; New York Coil Company, New York; William Roche, Standard dry batteries, New York; Pittsfield Spark Coil Company, Pittsfield, Mass.; Polyphase Ignition System Company, New York; Remy Electric Company, Anderson, Ind.; Rushmore Dynamo Works, Plainfield, N. J.; C. F. Splitdorf, New York; Standard Welding Company, Cleveland, Ohio; United Electrical Manufacturing Company, New York, and Warner Instrument Company, Beloit, Wis.

NEW BOOKS.

ALTERNATING CURRENTS. By George T. Hanchett. New York: John Wiley & Sons. Cloth; 180 pages, 5 inches x 7¼ inches; numerous illustrations. Price, $1.00.

This is a highly meritorious effort to present an exposition of alternating-current principles which will be intelligible to students and others who either have not had sufficient mathematical training or have not the time and inclination to master heavier text books, such as those of Dr. Steinmetz. The author is a thoroughly trained practising engineer and knows his subject; his treatment of it is practical and full of common sense, and the book should be of much value to those for whom it was written. There are some little obscurities of diction, but in the main the work is clean-cut and easily followed.

ELECTRICAL ENGINEERING. By E. Rosenberg. Translated from the German by W. W. H. Gee and Carl Kinsbrunner. New York: John Wiley & Sons. Cloth: 270 pages, 5½ ins. x 9 ins.; 263 illustrations. Price, $1.50.

Thus is a semi-popular elementary book, containing a good deal of general information concerning electrical apparatus and its uses, but very little educational materal. It should serve excellently the purpose of anyone who desires to acquire merely a casual knowledge of the subject without desiring to pursue the study seriously.

NORTHWESTERN CONVENTION NOTES.

Quite a number of manufacturing and supply houses were represented at the annual convention of the Northwestern Electrical Association held in the Hotel Pfister, Milwaukee, on January 18 and 19, and many of these made exhibits in parlors.

Porter & Berg, Chicago, had an interesting exhibit in the corridor of the hotel consisting of Locke high-tension insulators.

Julius Andrae & Sons Company, Milwaukee, exhibited the various lines handled by it, including the G. I. and Westinghouse products.

The Wagner Electric Manufacturing Company, St. Louis, received its visitors in one of the parlors and distributed literature pertaining to its products.

The Fort Wayne Electric Works, Fort Wayne, Ind., took up headquarters in one of the parlors where an exhibit was made of the well-known arc lamps made by the company.

The Federal Electric Company, Chicago, displayed its enameled steel electric signs, some of which were flashed with Dull's flashers which were exhibited in the same room.

The Electric Storage Battery Company had its representatives stationed in the southwest parlor where they received the friends and patrons of the company and distributed advertising literature.

The Western Display Company, St. Paul, had a large "Reflectric" sign displayed in a prominent position in the hall. This sign is of enameled steel with lights concealed in reflectors above the sign.

The Allis-Chalmers-Bullock interests distributed a handsome souvenir badge and watch charm having the company's "ours the four powers" design. Visitors were entertained in one of the parlors and printed matter was distributed.

The Duncan Electric Manufacturing Company, Lafayette, Ind., exhibited a number of its meters and had placards posted throughout the hotel calling attention to the exposed jewel features of the meter.

The Benjamin Electric Manufacturing Company, Chicago, had an exhibit in connection with the exhibit of the Holophane Glass Company. The company's new wireless cluster "Arc Burst" was shown with lamps equipped with Pagoda reflectors.

The Nernst Lamp Company had a number of its lamps on exhibition which, however, were not lighted, owing to the fact that alternating current was not available at the hotel. The construction of the lamp was clearly shown in the disassembled parts.

The General Electric Company made its headquarters in the southeast parlor. A number of recent types of circuit-breakers made by the company were on exhibition. Printed matter relating to the company's many and varied products was distributed.

The Crouse-Hinds Company, Syracuse, N. Y., exhibited its new receptacles for sign and decorative work. The receptacles were made up to resemble a porcelain insulator and the board upon which these were fastened also contained some of the company's switches and outlet boxes.

The Holophane Glass Company, New York, had one of its demonstrating outfits set up in one of the parlors. This was in charge of C. A. Howe, general sales manager, and H. E. Watson. The comparative amount of useful light obtained with and without the use of Holophane globes was forcibly shown, as well as the superiority of the Holophane over other forms of globes.

The National Electric Company, Milwaukee, made special arrangements for the reception and entertainment of its friends at the convention. A handsome exhibit was set up in one of the parlors and some bromide enlargements hung on the walls gave an excellent idea of some of the larger electrical machinery made by the company. A publication entitled the "National Electrical Catechism" was presented to each visitor; this is the latest advertising literature of the company, and is extremely interesting. Of special interest to the visitors was the Lundell "Universal" motor, of which the special feature of construction is a field magnet composed entirely of laminations. Other features of novelty are comprised in this motor, which is unique in many particulars; among these may be mentioned an improved brush-holder and also the improved design by which commutation is obtained over an exceptionally wide range. Invitations, which included a pass over the street railway system, were given to the members of the Association to visit the works of the National Electric Company, which are pleasantly situated at the northeastern part of the city. A souvenir watch charm was also distributed.

OBITUARY.

E. H. MULLIN.—As we go to press we learn with extreme regret of the sudden death on January 25th of Edward H. Mullin, of the General Electric Company's advertising department. Mr. Mullin had been in rather poor health for a few weeks prior to his death, but was not considered seriously ill. He had remained at home during his

THE LATE EDWARD H. MULLIN.

indisposition more as a precautionary measure than because of physical inability to get about, and expected, on the last day of his life, to get back to his office within a day or two. His death, which was apparently due to heart trouble, occurred without the slightest warning while he was reading

aloud to his wife. Mr. Mullin was born in Castlederg, Ireland, October 22, 1859. His early education was received at Methodist College and Queen's College, Belfast, and he took the degree of B. A. in an honor course in Physics and Chemistry in Queen's University in 1881. Shortly after this he came to this country and in 1887 joined the New York *Sun's* staff; in 1895 he left the *Sun* and took charge of the technical reportorial work of the *Times*. From 1895 to 1898 he contributed to many literary and technical publications. Early in 1898 he joined the New York staff of the General Electric Company, taking charge of the relations between that company and the technical press, and he occupied this position up to the time of his death. He leaves a widow.

PERSONAL.

MR. A. L. ENGLISH has been appointed manager of the Citizens' Gas & Electric Company, Council Bluffs, Ia.

MR. ALEXANDER WEBB, of New York, has been elected treasurer of the Youngstown (O.) Consolidated Gas & Electric Company.

MR. EDWARD MILLER has been appointed manager of the promotion department of the Cincinnati Gas & Electric Company, Cincinnati, to succeed Mr. H. C. Hutchinson, who resigned recently.

MR. W. B. ELLIOTT, who for several years has been works manager of the C. & C. Electric Company, has been appointed general manager of the company to succeed Mr. Campbell Scott, whose resignation was noted in this column last month.

MR. W. S. KEMP, for the past ten years treasurer of the Brookline National Bank, has been elected secretary and treasurer of the Holtzer-Cabot Electric Company, Boston, Mass., succeeding Mr. Ira A. Foster who recently resigned the joint position.

MR. HENRY C. MORTIMER, JR., formerly of the General Electric Inspection Company, recently severed his connection there to join the New York staff of the Crocker-Wheeler Company, as assistant to Mr. F. B. De Gress, manager of the New York office.

MR. C. J. PURDY, for some time past New York sales agent of the Munder Electric Company, recently resigned that position to accept the general managership of the American Incandescent Lamp Company. Mr. Purdy's headquarters are at 26 Cortlandt Street, New York.

MR. ALFRED J. THOMPSON, who was connected with the sales department of the Crocker-Wheeler Company for some time, has joined the forces of the Allis-Chalmers Company and will devote his time to the sales of the Bullock lighting and power apparatus in New York and vicinity.

MR. EDWARD VAN WINKLE, formerly associated with Mr. Charles R. Pratt in consulting engineering, has established offices at 160 Fifth Avenue, New York, and will continue alone in the same line of work, Mr. Pratt having retired from consulting engineering to devote his entire time to his elevator safety devices.

MR. GEORGE MAGALHAES, who has been for some time on the engineering staff of the Electric Controller & Supply Company, Cleveland, Ohio, has been appointed manager of that company's eastern office at 136 Liberty Street, New York. Mr. Magalhaes is a graduate of Columbia University and is thoroughly familiar with all of the company's products.

MR. FRANK FERGUSON, a well-known builder of boilers and engines, and Mr. Daniel Killion, well known in the electrical field, have organized a company under the style of Ferguson & Killion Company, Inc., for the purpose of building boilers, engines, electric machinery and complete power plants. The headquarters of the new company are in the Betz Building, Philadelphia.

MR. ARCHIBALD B. BUSH, for many years connected with the sales department of Manning, Maxwell and Moore has severed his connection with that house and has taken up the Eastern sales agency of The Hisey-Wolf Machine Company, of Cincinnati, Ohio, manufacturers of portable electric driven grinders and drills. Mr. Bush's headquarters will be at 120 Liberty Street, New York City.

MR. W. S. MONTGOMERY, who was for several years manager for the Conover Condenser Company, and during the past year manager of the Payne Engine Company's New York Office, has resigned the latter position to form a partnership with Mr. G. M. Rogers, under the style of Rogers & Montgomery, for the purpose of handling small labor-saving tools and hardware specialties. The new firm's offices are at 147 West 23rd Street, New York.

MR. CHARLES R. UNDERHILL, formerly chief engineer of the Varley Duplex Magnet Company, has engaged in consulting engineering on his own account, with headquarters at 55 Liberty Street, New York. Mr. Underhill will make a specialty of the design of electromagnets and solenoids in general, but particularly for heavy-duty work. He will also take contracts for the complete construction of magnets and solenoids to perform a given duty.

MAJ. GEORGE O. SQUIER, of the United States Signal Corps, recently made an exhaustive report to the Chief Signal Officer of the California Department on the absorption of magnetic waves by living vegetable organisms, the report being based on an incident which occurred at a joint encampment of regular troops and organized militia at American Lake, Wash. The report has been published in pamphlet form and makes extremely interesting reading.

MR. JAMES G. ROBERTSON, who has represented A. L. Ide & Sons at St. Paul, Minn., for the past 15 years, has been appointed manager of the New York office of that firm and will push the sale of Ideal engines in the East. Mr. Robertson has established headquarters in the Bowling Green Building, New York, and his staff thus far includes Mr. G. B. Ferrier, Jr., and Mr. Stewart G. Fuller. The western Ide office has been put in charge of Mr. Robertson's brother, Mr. A. R. Robertson.

MR. E. S. LEA, who made many friends in his position as sales manager for the De Laval Steam Turbine Company, has resigned that position and established headquarters at 42 Broadway, New York, as a consulting engineer. Mr. Lea has had wide experience in the design and construction of power plants and water works plants, as well as in the manufacture of machinery. He is a member of several technical bodies, including the American Institute of Electrical Engineers and the American Society of Mechanical Engineers.

TRADE PUBLICATIONS.

MULTIPLE-DUCT CONDUIT. Standard Vitrified Conduit Company, New York.—A handsomely executed folder containing illustrations of multiple-duct conduit and third-rail insulators.

OIL SWITCHES AND CIRCUIT-BREAKERS. Westinghouse Electric & Manufacturing Company. —Circular No. 1096, containing illustrated descriptions of oil circuit-breakers and oil switches, both manually and electrically operated.

RESISTANCE MEASURING INSTRUMENTS. Queen & Co., Inc., Philadelphia.—A bulletin of standard resistance boxes, resistance coils, slide-wire bridges, cylindrical bridges, Thomson portable bridges, portable testing sets and rheostats.

ELECTRICAL SPECIALTIES. Trumbull Electric Manufacturing Company, Plainville, Conn.—Catalogue No. 5, of standard size, devoted to Trumbull switches, fuse blocks, connectors, receptacles, rheostats, cut-outs, panelboards and cabinets.

CALENDAR. The Triumph Electric Company, Cincinnati, Ohio.—A hanging calendar, comprising an extremely attractive picture executed in colors on a heavy cardboard mount and a pad calendar attached to the mount beneath the picture.

HOISTING AND CONVEYING MACHINERY. McMyler Manufacturing Company, Cleveland, Ohio.—A well-executed catalogue of standard size, containing illustrations of cranes, derricks, conveyors, and other hoisting and conveying apparatus built by this company.

DENTAL LATHE MOTORS. The Holtzer-Cabot Electric Company, Boston, Mass.—A pocket-size pamphlet containing a very full illustrated description of the line of small machines indicated by the title. These are built in both alternating-current and direct-current types.

STEAM SPECIALTIES. Penberthy Injector Company, Detroit, Mich.—Catalogue No. 21, of standard size, containing very full illustrated descriptions of Penberthy injectors, foot valves, ejectors, steam rams, mufflers, low and high-water alarms, water gauges, force-feed oil pumps, oil cups, etc.

CALENDAR. National Carbon Company, Cleveland, Ohio.—A hanging calendar, carrying on the cardboard backing a well executed half-tone picture of a handsome woman, beneath which is attached a pad calendar differing from the usual form in that each monthly leaf contains a moonlight lighting schedule for that month.

FEMCO INCANDESCENT LAMPS. The Franklin Electric Manufacturing Company, Hartford, Conn.—A well-executed pamphlet of pocket size, containing illustrations and specifications of all of the standard incandescent lamps manufactured by this company. The company has recently added to its line some reflector lamps, the reflector in which is removable.

SWITCHBOARDS FOR SMALL EXCHANGES.—The North Electric Company, Cleveland, Ohio.—Bulletin No. 26, containing an illustrated and full detailed description of switching stations for small or isolated telephone exchanges. The information contained in the bulletin is unusually complete and includes a full diagram of circuit connections.

THE INSULATOR BOOK. The Locke Insulator Manufacturing Company, Victor, N. Y.—Catalogue No. 8, of standard size, containing illustrations and data relating to the complete line of Locke porcelain and glass insulators for electric light and power service. The catalogue also contains some interesting notes on the testing and manufacture of insulators.

WHAT THE HINDOOS DO. The Buckeye Electric Company, Cleveland, Ohio.—An illustrated folder, pointing out the Hindoo custom of following up a messenger to make sure that he discharges the duty with which he is entrusted, the application being that the Buckeye Company systematically follows up its customers and keeps them posted as to the merits of Buckeye lamps.

BALL BEARINGS. The Hess-Bright Manufacturing Company, Philadelphia.—Catalogue No. 68, of standard size, containing illustrated descriptions and tabulated data relating to a special form of ball bearing manufactured for heavy-duty work. This form of bearing is used on dynamos and motors of a good many European manufacturers and is coming more and more into use in this country.

CALENDAR. The Holtzer-Cabot Electric Company, Boston.—An attractive and most sensible form of calendar, consisting of three sheets of heavy cardboard linked together by cords; the upper sheet bearing pictures of Holtzer-Cabot motors, the middle sheet carrying a pad calendar, which is also illustrated by pictures of various Holtzer-Cabot apparatus, and the lower sheet containing pictures of the factory and some of the company's telephone apparatus.

VARIABLE SPEED MOTORS. Electro Dynamic Company, Bayonne, N. J.—Circular No. 1-B, containing an illustrated description of the company's inter-pole direct-current motor for variable speed service. This machine is provided with small intermediate magnet poles which supply a commutating field and permit the weakening of the main field without sparking. The description is exceptionally well written and technically accurate.

BUSINESS NEWS.

THE WIRT ELECTRIC COMPANY, INC., of Philadelphia, has removed its New York office to 15 Cortlandt Street.

THE SHEPHERD ENGINEERING COMPANY, Franklin, Pa., has been awarded a gold medal for its engines by the Louisiana Purchase Exposition.

HOLOPHANE GLASS COMPANY has consolidated its Chicago and New York offices in the Glackner Building, 227 Fulton Street, New York.

THE BRISTOL COMPANY, Waterbury, Conn., has been notified by the St. Louis Exposition officials of the award of a gold medal for its exhibit of recording instruments.

A. L. IDE & SONS, the well-known builders of the Ideal steam engines, have established eastern headquarters at 11 Broadway, New York, through which all export, New England and Middle States business will be transacted hereafter.

THE WILLIAM TOD COMPANY, Youngstown, Ohio, has received a contract for a new pumping engine for the Kansas City (Mo.) water works; the cost of the engine will be about $140,000.

THE LAGONDA MANUFACTURING COMPANY, Springfield, Ohio, makers of the well-known Weinland tube cleaners, reports a most encouraging business outlook for the present year. The company's business during December was the largest of any single month since it was organized.

PITTSBURG GAGE & SUPPLY COMPANY, Pittsburg, Pa., has been compelled by the growth of its business to enlarge its quarters, and has accordingly leased another store and warehouse at 321 Water Street, adjoining its present warehouse. The new building is four stories high and covers a plot 50x200 feet.

THE WESCO SUPPLY COMPANY, St. Louis, Mo., has established a branch office and warehouse at Fort Worth, Tex., for the convenience of its southwestern trade. The new office is in charge of Mr. V. E. Raggio, previously sales manager of the company. A complete stock of apparatus and supplies will be carried at the Fort Worth branch.

CENTURY ELECTRIC COMPANY, St. Louis, Mo., has just moved its main office and works from 1007 Locust Street to 404 North Fourth Street, where much larger and more suitable quarters have been obtained. The move was rendered necessary by the rapid increase in the company's ceiling fan and power motor business.

THE ALLIS-CHALMERS COMPANY, Milwaukee, Wis., has established a branch office in Philadelphia in the Land Title Building, in charge of Mr. W. A. Wood. The Philadelphia offices of the Bullock Company have, of course, been consolidated with the new offices of the Allis-Chalmers Company.

THE BURT MANUFACTURING COMPANY, Akron, Ohio, recently made a shipment of 21 Cross oil filters to Havana, Cuba. The company has worked up an extensive trade in foreign countries, recent shipments including nine filters and six exhaust heads to Sidney, Australia; eighteen oil filters to St. Petersburg, Russia; three to Calcutta, India, and four to Spain.

STANLEY ELECTRIC MANUFACTURING COMPANY, Pittsfield, Mass., recently secured from the California Gas & Electric Corporation, of San Francisco, an order for two frequency changers of 5000 kilowatts capacity each, for use in connection with the railway work of the Corporation. The contract includes also transformers aggregating 12,000 kilowatts capacity.

THE HOLTZER-CABOT ELECTRIC COMPANY, Boston, Mass., is the subject of an interesting sketch in a recent number of *The Chronicle*, a Brookline, (Mass.) weekly publication. A brief history of the company is given, together with personal sketches of its officials and some interesting information as to the business policy and routine of the establishment.

GARTON-DANIELS COMPANY, Keokuk, Ia., advises us that each year a demand for a higher class of materials is noted, this being particularly true in the lightning arrester field. During the present winter the company has made up the largest stock of lightning arresters that it has ever prepared before, feeling confident of a decided increase of business activity during the coming year.

THE BRUCE-MERIAM-ABBOTT COMPANY is the style of a new organization composed of the Meriam-Abbott Company and The Bruce Company, of Cleveland, Ohio, who recently joined forces. The new company will continue the manufacture of the vertical twin-cylinder gas engiens and electric lighting plants formerly built by the Meriam-Abbott Company and the Bruce-Collins automatic engines formerly built by The Bruce Company.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY reports a brisk demand for its electrical apparatus. Among recent contracts were one for two 1000-kw. turbine-generator outfits for the Haverhill (Mass.) Electric Company, one for two 1500-kw. outfits for the Rochester, Syracuse & Eastern Railroad, and one for a 1000-kw. set for the Springfield (Mass.) Electric Light Company. The Westinghouse Company has also closed a contract with the Ontario Power Company for a 10,000-h.p. alternating-current generator; this is in addition to contracts for three similar machines previously closed. The generators are of the revolving-field type designed for direct connection to water-wheels.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

DOTHAN.—Plans are being formulated for rather extensive improvements to the city electric light plant. These include the installation of a 250-kw. revolving-field alternator and a 375-h.p. engine. The lighting circuits will be changed from direct to alternating current and fifty series enclosed arc lamps will probably be put in, which will increase the number now in use by twenty-three.

DADEVILLE.—The Tallapoosa Water Power & Electric Company has been organized to develop 8000 horse-power on the Tallapoosa River in the vicinity of Sturdevant. The power will be used for manufacturing purposes. The company is capitalized at $500,000, and Mrs. R. T. Parker, of this city, is reported to be one of the incorporators.

TALLADEGA.—The plant of the Talladega Electric Power Company is being greatly improved and the line for transmitting the current to this city has been completed.

UNIONTOWN.—The City of Uniontown, W. J. Vaiden, Mayor, is arranging to remodel the city light and water plant. S. T. Townsend, superintendent of the plant, writes that they are in the market for a complete alternating-current system, including 100-kw. generators, transformers, switchboard and instruments, regulators for arc lighting, and all necessary apparatus for a 25-light system; a 150-h.p. engine will also be required to drive the generator. The plant is to be removed from its present location to a point near the railway tracks.

ARKANSAS.

CAMDEN.—A company composed of Little Rock, Camden and St. Louis business men has purchased the electric light plant heretofore operated by the Camden Power & Light Company. J. A. Trawick, president of the Little Rock Railway & Electric Company, is president of the new concern and J. A. Van Etten, of this city, is secretary. Others interested in the enterprise are George D. Rosenthal and William Hand, of St. Louis, and W. K. Ramsey, of Camden, who was treasurer of the old company.

MAGNOLIA.—Advices received from the Magnolia Ice & Light Company state that another 40-kw. 250-volt direct-current generator has been installed recently. When the improvements are completed the company's system will comprise convertible two and three-wire circuits operated at 220 and 440 volts, and the equipment will consist of three engines, two automatic engines running at 300 r.p.m. and one Corliss engine.

ENGLAND.—It is understood that the Council is considering the establishment of a municipal lighting plant.

CALIFORNIA.

COLTON.—There is reported to be a movement here towards establishing a municipal electric light and power plant.

CALISTOGA.—G. S. Cutler, of this city, has been granted a franchise to construct and operate an electric light system here.

SAN FRANCISCO.—The Consolidated Heat, Light & Power Company has been incorporated with a capital of $300,000, by William Thomas, Mark L. Gerstle, Robert N. Frick and others.

COALINGA.—The Board of Supervisors at Fresno has granted to F. W. Bray a franchise to construct an electric light plant, a natural or artificial gas plant and a water works system in this city.

ALAMEDA.—The contract for the new machinery, which is to be installed in the municipal lighting plant, has been let to Charles C. Moore & Co., of San Francisco. The contract is for $12,607 and includes an engine and generator.

REDDING.—The North Mountain Power Company's plant in Junction City is now completed and ready to furnish power to Eureka and adjoining towns.

VISALIA.—The Mt. Whitney Power Company is erecting a sub-station at Dinuba and now has in course of construction about twenty miles of high-tension transmission line and twenty miles of distributing lines.

UKIAH.—The present capacity of the municipal lighting plant has become inadequate to meet the requirements, but it has not been decided yet whether to enlarge the plant or to purchase additional power from some outside source.

NEWMAN.—The Newman Light & Power Company has been incorporated to manufacture and sell electric light and power. The company is capitalized at $20,000, and numbers among its directors Mrs. Annie McDonald, of San Francisco; Joseph McDonald, of Nappa City, and John G. McDonald, of this city.

LOS ANGELES.—The Edison Electric Company has placed contracts for generators and impulse wheels for its 25,000-kw. station under construction on the Kern River. Steel towers 75 feet high will be used on the 120-mile transmission line to this city.

EUREKA.—The loss on the plant of the Eureka Lighting Company, which was destroyed by fire recently, is estimated at $30,000, a little more than half of it being covered by insurance. Five dynamos, together with other machinery, were destroyed.

INDIO.—The Indio Light, Water & Ice Company has filed articles of incorporation, with a capital stock of $30,000. The directors are W. F. Everett, H. Kuhl, H. E. Tallant and J. S. Hunter, all of this city. Mr. Everett, the secretary, writes that it is proposed to construct water works, an electric light plant and a 10-ton refrigerating and ice plant.

ARCATA.—Brousse Prizard, president of the Arcata Light & Power Company states that it is proposed to purchase at once complete equipment for a transformer station, including three 100-kw. transformers, one 10,000-volt oil switch, and 80 assorted sizes of meters from 5 to 10 amperes.

SAN DIEGO.—Articles of incorporation have been filed for the United Light, Fuel & Power Company, capitalized at $500,000. The majority of the stock, it is said, is owned by John D. Spreckels, of San Francisco. The corporation proposes to construct and operate plants for the generation and distribution of electricity and gas for lighting, fuel and power purposes in this State. There are five directors.

HOLTVILLE.—F. C. Bayless, formerly of Redlands, is now superintendent of the Holton Town Company and the Holton Power Company, of this city. He writes that the Holton Power Company is erecting a large plant on the desert, near this place. A power canal has been constructed, 150 feet wide on the bottom with levies 50 feet thick at the base and 11.1 feet high at the lower end. A 52-inch pipe line extends from the end of the canal to the power house 1500 feet below.

SAN JOSE.—J. J. Inman, M. E. Page, W. H. Baugh, and others have filed articles of incorporation for the National Park Electric Power Company, with a capital stock of $250,000.

SAN FRANCISCO.—The Culiacan Electric Company has been incorporated by Sidney Sprout, Isidor Gutte, F. G. Brane and others. The company has a capital of $300,000.

SAN DIEGO.—The San Diego Gas & Electric Company has installed in its plant in this city a vertical McIntosh & Seymour engine rated at 450 horse-power and direct-connected to a 220-kw. three-phase generator. The cost of the new machinery is estimated at $30,000.

ESCANDIDO.—The land owners of the Escondido Irrigation District now own the entire water system. A company has been organized to take over the system and other assets and will soon commence extensive improvements to the plant. Among these improvements will be the erection of a 400-h.p. water power plant, the power to be transmitted to this city by electricity for lighting and power purposes.

COLORADO.

PAONIA.—James Beezley is reported to have sold out his electric lighting business, but the details of the transaction have not been made public yet.

GLENWOOD SPRINGS.—Work will soon be commenced on the power plant of the Colorado Irrigation & Power Company in the Canyon of the Grand River above this place. L. W. Beard is chief engineer and J. R. De Remeer is local representative of the company.

SALIDA.—The Edison Electric Company has practically completed its plans for the erection of a power plant at Arborville on the south fork of the Arkansas River, fifteen miles north of Salida. Ten carloads of machinery, consisting of turbine wheels and piping, have been ordered. The enterprise will involve the expenditure of $75,000 and is backed by local capital. The plan is to furnish cheap electric power to Salida.

CONNECTICUT.

ROCKVILLE.—Mayor Foster in his annual message has recommended municipal ownership of the electric light plant.

GAYLORDSVILLE.—The New Milford Power Company states that it contemplates the erection of several new plants in the near future, all on the Housatonic River.

HARTFORD.—Part of the new plant of the Hartford Electric Light Company at Dutch Point has been put into service, about 600 horse-power being supplied to the city by the company .

DANBURY.—The Danbury Power Company is said to be preparing plans for the establishment of dams and power stations on the Rocky River at New Milford and the Still River at Lanesville and Brookfield.

NORWALK.—The Connecticut Railway & Lighting Company advertises its intention of applying to the next Legislature for an extension of some of its charter rights and those of its constituent companies which expire July 1, 1905.

HARTFORD.—The Berkshire Power Company has awarded the contract for the initial electrical equipment to go in its water power plant to the Westinghouse Electric & Manufacturing Company. The contract calls for two units of 300 kilowatts capacity each.

NORWICH.—R. L. Warner, the New England manager of the Westinghouse Electric Company, is reported to have secured rights along the Quinebaug and Shetucket Rivers and proposes to construct a power plant in this section. The idea is to get a charter from the Legislature and sell power in this section of the State.

NORWICH.—A petition is to be presented to the general assembly at its next session by G. O. Jackson, E. W. Higgins and C. W. Comstock for the right, under the name of the Uncas Power Company, to manufacture, generate, transmit, deliver and sell electricity for any and all purposes in the towns of the county, with the exception of Norwich and New London, and for the right to distribute and sell electricity in Norwich and New London to the amount of not less than twenty-five horse-power per customer. The plant is to be located in Norwich.

CUBA.

MANZANILLO.—The electric light plant here is being overhauled by Mr. A. M. del Valle. The new plant is operated on the three-wire system with 250 volts on each side of the neutral, the generators being direct-current machines. The steam plant comprises Babcock & Wilcox boilers and compound condensing engines built by the Brush Electric Engineering Company, London. The fuel is anthracite coal dust, which is obtained without cost from ships carrying it as ballast; the coal dust is put through a process which makes it somewhat similar to soft coal. The municipal lighting is done by means of fifty arc lamps and 700 series incandescent lamps. The private lighting is almost entirely constant-potential incandescent lamps. Mr. del Valle desires catalogues from manufacturers of hydraulic and electrical apparatus, as the company will erect a new power house in the immediate future, in which the machinery will be driven by water power.

DELAWARE.

WILMINGTON.—The City Council will ask the Legislature for permission to borrow $200,000 for the construction of a municipal electric light plant.

DISTRICT OF COLUMBIA.

WASHINGTON.—The Red Cloud Electric Light & Mining Company has filed articles of incorporation, showing a capital stock of $300,000. George H. Corey, Eugene Schooley and J. L. Cohencious are the incorporators.

WASHINGTON.—Speaker Cannon is stated to have received from Bernard H. Green, Superintendent of the Congressional Library, a report recommending the construction of a central power station to supply all the uptown Government departments in the vicinity of the White House with light, heat and power. The report was made on a request by Congress last April. The plan provides for the removal of all boilers and engines from the departments in question, and the establishing of a single distributing point, with a system of conduits for the transmission of steam and electricity to the various scattered buildings. The estimated cost of the plant is $2,000,000, and it will cost about $200,000 a year to operate it.

FLORIDA.

OCALA.—The municipal electric light plant is being enlarged and the system changed over to alternating current.

TALLAHASSEE.—The equipment of the municipal electric light plant here has been increased recently by the addition of another unit.

GEORGIA.

DAWSON.—A new 150-h.p. boiler has been added recently to the municipal electric light plant equipment.

JONESBORO.—The city authorities are considering duplicating the electric plant here some time in the near future.

DECATUR.—The Decatur Electric Light, Power & Water Company recently added a 35-kw. dynamo to its plant equipment.

LITHONIA.—The new electric plant of the Panola Company, whose power house is about six miles from Lithonia, has been placed in operation.

SAVANNAH.—Local press reports state that the question of establishing a municipal electric light plant on the city lot is under consideration.

DOUGLAS.—The Savannah Electric Light & Power Company, of Savannah, has secured the contract for constructing an electric light plant here to cost $6250.

SAVANNAH.—Local reports state that the Savannah Lumber Company will install an electric light plant at its mill and supply power to private residences of the city.

FORT VALLEY.—Mayor J. L. Fincher writes that it is proposed to construct an electric light plant to cost about $6000, the contracts for which will probably be let in April.

CRAWFORD.—It has been decided at an election held by the citizens of this place to light the town by electric lights. The contract has been closed for the erection of arc lights at an early date.

McRAE.—Plans are being considered for extending the service of the municipal lighting plant to Helena, Ga. If this is done, four arc lights and 200 16-c.p. incandescent lights will be installed in that town.

GREENSBORO.—The Council has closed a contract with the Southern Electric Supply Company, of Athens, for the construction of the electric light plant here, at a cost of about $10,000. By the terms of the contract, the lights are to be turned on not later than April 1, the contractor forfeiting $10 per day for every day after that date that the plant is not completed.

COVINGTON.—On the morning of December 27 the city electric light plant here was completely destroyed by the explosion of a boiler, the engineer of the plant being instantly killed. The force of the explosion was so great as to hurl the 80-h.p. boilers a distance of several hundred yards and scatter fragments of the building over two or three acres of ground. The loss is estimated at $12,000 with no insurance. Although temporary arrangements have been completed by which the city is again to have electric lights, it is probable that as soon as other plans can be devised the city will discontinue its lighting system. Owing to the fact that the plant has not been self-sustaining since its establishment four years ago, the annual expenditures being from $1800 to $2000 greater than the receipts, a strong sentiment has developed in opposition to city ownership. Before an entirely new plant can be installed, adequate to supply the city's demands, there will in all probability have to be another bond issue, which, it is feared, would be voted down when submitted to the people. To obviate this possibility, there is a rumor that a private corporation, composed of Covington capitalists, interested in the development of an immense water power in the southern part of Newton County, will offer to buy the electric light franchise from the city and inaugurate a system with an increased capacity that would be in keeping with the growth of the town. This water power, known as White's Shoals, on Alcovey River, ten miles from Covington, is said to be one of the largest water falls in middle Georgia, and if properly harnessed its power would be sufficient to operate all the machinery, as well as light a number of towns, within a radius of 10 or 15 miles, which would include Monticello, Jackson, Flovilla, Covington, Oxford, Mansfield and Newborn.

IDAHO.

GRANGEVILLE.—The Grangeville Electric Light & Power Company is running a line to Cottonwood by way of Denver, a distance of fifteen miles.

WALLACE.—Electric power from Spokane will operate the Mammoth mill. A branch line has been brought down the canyon from the point where the line to the Morning mine leaves the main line, a 150-h.p. motor has been installed, and the necessary changes are all but completed for the electric operation of this large concentrator by electric power transmitted nearly 100 miles.

POST FALLS.—The contracts for the electric and hydraulic machinery in the new plant to be

built by the Washington Water Power Company, of Spokane, Wash., at this point have been awarded. The electrical work is to be done by the General Electric Company. The main work will be commenced some time this month. The cost of machinery, warehouses and mills will be about $500,000. The initial installation will be about 9000 horse-power, with an ultimate capacity of 18,000 horse-power.

ILLINOIS.

TOLEDO.—It is intended to install larger machinery in the city electric light plant.

LENA.—Benfer Brothers, of Winslow, have petitioned for a franchise for a lighting plant.

ROCKFORD.—Reports state that J. C. Yeager has sold his electric light plant to Mr. Burdick, of Chicago.

EAST MOLINE.—F. C. Dunbar is said to be interested in the construction of an electric light plant here.

LA HARPE.—The La Harpe Electric Light & Power Company has recently installed a storage battery in its plant.

LAMOILLE.—Reports state that private parties are negotiating for the installation of an electric lighting system for the town.

CHICAGO.—A franchise has been granted to the Garts-Arnold Electric Company for the lighting of North Avenue, this city.

ONEIDA.—At the request of H. W. Crane, the City Council has granted a new franchise to the Oneida Light & Power Company.

COLLINSVILLE.—The Collinsville Electric Light, Heat & Power Company has recently installed a new 250-h.p. engine in its plant.

GIFFORD.—An electric light company has been organized by the citizens for establishing an electric light plant, which will be erected during the coming summer.

QUINCY.—The controlling interest in the Independent Light & Power Company, of this city, has been sold to a Chicago capitalist. The new manager will be N. J. Ferris, of Chicago.

DIXON.—The Lee County Lighting Company, of which John I. Beggs, of Milwaukee, is president, has purchased the plants and property of the Dixon Power & Lighting Company, of this city.

CHICAGO.—The Georgetown Electric Company has been organized with a capital of $15,000 to operate a heat, light and power plant. The incorporators are W. F. Brugman, A. M. Searle and C. C. Travis.

RED BUD.—J. A. Hamilton and A. B. Daah are among the organizers of the Red Bud Light & Power Company, which was recently incorporated with a capital of $20,000 to operate a lighting, heat and power plant.

PALMYRA.—The Waverly Telephone Company, which has the city contract for electric lights, states that if its business continues to grow as it has in the past it will be necessary to install another dynamo and engine in the near future.

CHILLICOTHE.—J. S. Daily, the enterprising proprietor of the Chillicothe Electric Light & Water Works, sends out a very dainty little calendar, which should serve to keep the recipients in mind of the giver throughout the year.

LINCOLN.—Of the $750,000 worth of bonds authorized by the Springfield & Northwestern Railway Company for the completion of its interurban line, it is reported that $150,000 will be devoted to the construction of a central power plant in this city.

EDWARDSVILLE.—The power plant of the Edwardsville Electric Light & Power Company has been purchased by the syndicate in control of the Illinois Traction Company's interurban road. New machinery will be installed, it is said, and the plant refitted throughout.

CHICAGO.—Bids will be received February 15 by S. D. Griffin, Clerk of the Board of Trustees Sanitary District, of Chicago, for furnishing and installing alternating-current generators and generators for exciters, the said generators to consist of four 4000-kw., 6600-volt three-phase 60-cycle generators, 164 r.p.m., and two 350-kw. 250-volt direct-current generators, 300 r.p.m.

CHICAGO.—In a recent issue of the Brooklyn (N. Y.) *Eagle*, Mayor Carter Harrison gives an interesting history of municipal lighting in Chicago up to 1904. He furnishes tables of statistics showing the comparative cost of maintenance per year since 1897 and the extensive improvements made in the meantime; also tables of the itemized cost of maintaining a single arc lamp, which are valuable in determining when economy has been or can be secured and in accounting for excessive expenditures. Mayor Harrison feels that the people of Chicago have received better service and cheaper rates on account of the municipal electric lighting system than would have been possible had the system been operated by private parties.

INDIANA.

LOOGOOTEE.—E. H. De Wolf has petitioned the Council for an electric light franchise.

CLAYTON.—Steps are being taken toward establishing an electric light plant in this city.

GREENFIELD.—It is proposed to increase the engine and boiler capacity of the electric light plant.

RIVERSIDE.—The Muncie Electric Light Company, of Muncie, has secured the contract for lighting Riverside for a term of five years at $50 per light per year.

BRAZIL.—The Brazil Electric Company is reported to have purchased property on Main Street as a site for a new power house which is to be erected in the early spring.

MARION.—It is reported that the power plant owned by the Pittsburg-Columbia Oil Company, which was recently destroyed by fire, will be rebuilt to be used for the generation of electricity.

ORLEANS.—Heise Bros. & Co. have been granted a franchise to construct and maintain an electric light plant in this town. They propose to begin work at once and have the plant in operation by April 1.

SHELBURN.—William Whaley and Noland B. Stadley, of Terre Haute, are reported to have secured a twenty-year franchise for city and commercial lighting in Shelburn. The plant will be located between Shelburn and Hymera.

ZIONSVILLE.—An electric light plant is to be installed in this town, for which the Indianapolis & Northwestern Traction Company will furnish the power. A sufficient number of arc lamps will be purchased to light the town thoroughly.

COLUMBUS.—It is stated that bids will be received February 2 by the Common Council for two 150-h.p. boilers designed for 150 pounds working pressure, and all necessary foundation work, brick settings, steam piping, smoke stacks, etc.

INDIANAPOLIS.—The Indianapolis Light & Power Company and the Marion County Hot Water Heating Company have been merged into a single corporation to be known as the Indianapolis Light & Heat Company. The company will manufacture and sell electricity for light and power and will furnish hot water heat in the city of Indianapolis. The capital stock of the new company will be $1,000,000.

INDIAN TERRITORY.

CADDO.—The Choctaw Cotton & Power Company has been succeeded in business here by the Caddo Light & Power Company.

CHICKASHA.—Mr. Ross, formerly of the Ross Electric Company, of Lincoln, Neb., has sold out his business in that city and will move to Chickasha, where he will assume the management of the Chickasha Light & Power Company.

MUSCOGEE.—The Commercial Club has taken up a project for making use of the falls on Grand River ten miles from this city, to generate power for transmission to the town. Engineers have been employed to locate the best site for a power house and as soon as the plans can be completed the Commercial Club will undertake to finance the deal.

IOWA.

WAVERLY.—The Healey Electric Light Company has sold out its business.

COLUMBUS JUNCTION.—The Council has under consideration the matter of constructing an electric light plant.

GUTTENBERG.—The Guttenberg Electric Light Company contemplates establishing a power circuit for day service.

OSCEOLA.—The electric light plant here is to be enlarged and a day circuit for power purposes will be added. A hot water plant is also to be installed.

BURLINGTON.—Plans are on foot for the organization of a stock company for the purpose of putting in an electric light plant at West Burlington.

CHARLES CITY.—The Charles City Light & Heat Company is considering changing its lighting circuits from the open arc to the series enclosed arc system.

OTTUMWA.—The Ottumwa Traction & Light Company is having plans prepared for a new power house to be built in the spring at an approximate cost of $25,000.

MARSHALLTOWN.—City Clerk L. Derby writes that it is proposed to increase the number of city arc lights from 130 to 200. The expense of installing the new lights is estimated at about $8000.

CHARITON.—The city electric light plant will be rebuilt at a cost of about $40,000. New machinery has been purchased and it is expected to have the system in operation by spring. The entire system will be remodeled, many of the main wires having been either totally destroyed or badly damaged by the big fires last winter and spring.

WATERLOO.—The Waterloo & Cedar Falls Gas & Electric Light Company has been incorporated with a capital of $595,000, with headquarters in this city. The company will engage in a general gas and electric business, but was incorporated with the principal object of erecting a gas plant at Cedar Falls, where a franchise was recently granted. The directors are J. H. Leavitt, G. E. Lichty, George McLean, and others.

KANSAS.

TOPEKA.—The advisability of changing from direct to alternating-current series enclosed-arc lights is being considered.

STERLING.—A gas engine and an additional dynamo are to be installed in the electric light plant for the purpose of operating a day circuit.

BRONSON.—The Bronson Light & Telephone Company has secured a franchise to operate lighting and telephone systems in this city and is said to be ready for business.

ANTHONY.—W. A. Miller, chairman of the committee on arrangements for the establishment of an electric light plant for the city, writes that he would like to correspond with parties interested in such a project.

HAYS CITY.—Justus Bissing, proprietor of the Hays City Electric Light Plant, is arranging to operate his lighting circuits from dusk till morning every night instead of on a moonlight schedule and only until 12:30 p. m. He also expects to install a condenser in the early spring.

KENTUCKY.

MAYFIELD.—The Mayfield Water & Light Company recently intalled a 300-kw., direct-connected, 60-cycle, two-phase alternator in its lighting plant.

LOUISIANA.

LAKE CHARLES.—The City Council is reported to be considering the establishment of an electric light plant.

DONALDSONVILLE.—New poles and overhead lines are being erected in connection with the city lighting plant, besides some other minor improvements.

MARKSVILLE.—Arrangements are being made for the purchase of the private electric lighting plant here by the city, in connection with which a water works system will be installed. Plans and specifications for the latter are in preparation.

MAINE.

KENNEBUNK.—The Kennebunk Electric Light Company will probably add another unit to its equipment the early part of this year.

BANGOR.—The Council is said to be considering the advisability of increasing the capacity of

the city lighting plant. M. H. Rideout is superintendent of the plant.

PORTLAND.—The National Heat, Light & Power Company, of this city, has been incorporated with a capital of $5,000,000. M. W. Baldwin is president and J. J. Herman is treasurer.

PORTLAND.—The Northwestern Power Company has filed articles of incorporation, stating its capital stock to be $10,000,000. J. C. Rice, of Boston, is president, and C. N. Drummond, of this city, treasurer.

PITTSFIELD.—The Sebasticook Power Company has started up its machinery for business, and has begun furnishing electricity to light the homes, offices, stores and streets of Pittsfield. The electrical machinery includes three 300-kw., three-phase generators and one 100-kw. machine of the same kind. There will also be two 25-kw., moderate-speed exciters of 125 volts, either machine being capable of exciting all three of the generators. As soon as all is in complete working working order, the company will furnish power and light to various industries.

MARYLAND.

SNOWHILL.—The capacity of the Snowhill Electric Light & Power Company's plant has recently been increased to 1800 lights and two direct-current generators have been added.

BALTIMORE.—The United Electric Light & Power Company has purchased a majority of the stock of the Consolidated Gas Company. This is the beginning of the consummation of plans contemplating the consolidation of the United Electric Light & Power Company and the Gas Company.

ELLICOTT CITY.—Plans are being formulated by the Patapsco Electric Light & Power Company for the establishment of a power house on the Patapsco river, below this city. It is claimed that in view of the excellent water power afforded by the river at the point selected the operations can be made very profitable.

BALTIMORE.—Mr. W. J. McManigal, an electrical expert, has been appointed general manager of the new electric light and power department of the Maryland Telephone and Telegraph Company. He is a native of New York and about 50 years old. He has spent most of his business life in the West and has had about 15 years' experience in the operation of electric light and power plants. Mr. McManigal was general manager of the big plant at Omaha, Neb., and superintended the construction of the $6,000,000 plant that is being built at St. Louis when he accepted the position with the Maryland Telephone Company. He is married and will move his family from St. Louis to Baltimore. H. W. Webb, vice-president of the Maryland Telephone Company, states that work is progressing very satisfactorily on the construction of the new electric light and power plant along the water front in South Baltimore, and that it will be rushed as fast as possible, with the hope of having the establishment ready for operation about July 1, 1905.

MASSACHUSETTS.

CHELSEA.—W. M. McDonald and others have petitioned for a public hearing upon the proposition to purchase a municipal lighting plant.

MELROSE.—Mayor Buttrick, in his annual message, is reported to have recommended that steps be taken to establish a municipal lighting plant.

FAIRHAVEN.—The Mansfield municipal electric lighting plant is now supplying power to the Bay State Tap & Die Company, of this city, for the operation of its plant.

MANSFIELD.—It was voted at a recent town meeting to appropriate $1900 for an increase in the commercial department of the electric lighting system and to light the town hall and library by electricity.

BOSTON.—The Common Council and the Board of Aldermen have passed an order authorizing the city to construct or lease and maintain one or more plants for the manufacture and distribution of gas and electricity.

SPRINGFIELD.—The Springfield Electric Light Company has closed a contract with the Westinghouse Electric & Manufacturing Company for a 1000-kw. outfit with exciter. The contract also includes two 500-kw. rotary converters and four 300-kw. transformers.

HOLYOKE.—The contracts for the new machinery for the municipal electric plant have been let. The General Electric Company is to furnish a 500-kw. generator and a steam turbine to operate the same. The contract for three 250-h.p. Manning steam boilers was awarded to Coghlan's Holyoke steam boiler works for $6600. It is expected that the new apparatus will be in running order about May 1.

PALMER.—The annual meeting of the Central Massachusetts Electric Company was recently held in this city and the following officers elected: President, C. E. Fish; vice-president, G. C. Flint; manager, A. J. Purinton; treasurer, C. B. Fiske; clerk, A. J. Purinton. The officers and the following-named gentlemen comprise the board of directors: G. E. Fuller, of Monson; Edward Fairbanks and W. H. Fairbanks, of Warren; A. W. Paige and C. F. Grannis, of Bridgeport, Conn.

HAVERHILL.—The controlling interest in the Haverhill Electric Company, much of the stock of which is held in New Haven, Conn., has been acquired by the same interests that control several gas and electric companies in Massachusetts, including the Springfield Gaslight, the Malden Electric and the Suburban Gas and Electric companies of Revere and Winthrop, Mass. The Haverhill company is capitalized at $150,000 and is a growing and prosperous concern. It pays an annual dividend of 8 per cent. The directors of the Springfield Gas-light Company, who now control the Haverhill and other companies, are C. H. Terney, of Hartford; F. P. Royce, Oakes Ames and H. P. Ward, of Boston, Mass.; P. F. Thompson, of New York; Herbert C. Warren, Edwin Bradley and Samuel A. York, of New Haven. The Haverhill company is to be operated as heretofore, and it is stated that no consolidation of plants is planned.

CHICOPEE.—The annual report of the electric light department of Chicopee was filed yesterday with the City Clerk, and has some interesting features. The electric light department shows that the plant and equipments have increased in value $66,420 since it was first operated. The manufacturing and distributing cost have increased yearly, mainly for the reason that the plant has been called upon to do more work each year. The increase in this cost for the past year over that of the previous year was $802. The income from incandescent lights sold for commercial and domestic purposes has been on the increase, last year's margin being $1562. There has been a steady increase in the income from incandescent lights furnished city buildings and other city property, but the past year shows a decrease of $177 from that of 1903, which is due to the fact that the West Springfield bridge is out of existence. The income from city arc lights shows an increase yearly, with $653 for this year's net over last year. There are 188 street arc lights. The net income over manufacturing expenses of all classes of light furnished for this year was $7169, but the fixed charges of bonds and interest to be set off against this is $7587, or a net bookkeeping loss of $418. On October 10 the plant began to work 24 hours a day, and now furnishes power as well as light.

MICHIGAN.

SAUGATUCK.—A franchise has been granted to Charles Floyd and B. Van Raalte, Jr., to construct and operate an electric light and power plant.

ANN ARBOR.—City Clerk Granger writes, in regard to the lighting of the city streets, that plans are now being prepared but no definite action has yet been taken.

PERRY.—The Standard Heating & Lighting Company, of Detroit, has secured from the Village Council a contract to light the streets of this village and will soon begin the erection of a plant.

DETROIT.—Frank R. Mistersky, chief electrician of the municipal lighting plant, has been promoted to the position of assistant superintendent to succeed A. S. Hatch who has resigned. Mr. Mistersky will be succeeded by W. A. Andrews.

ST. LOUIS.—Burton E. Lucas, superintendent of the city light, plant, has resigned that position to assume the management of the Harbor Springs (Mich.) electric light plant. Previous to his connection with the St. Louis plant, Mr. Lucas was superintendent of the Ovid electric light and water works.

KALAMAZOO.—The Kalamazoo Valley Electric Company has been reorganized as the Commonwealth Power Company with a capital of $4,000,000. It is the intention of the company to increase the capacity of its plant sufficiently to enable it to furnish power for electric roads which will be built between this city and Grand Rapids in the near future. William A. Foote is president of the new company, and C. H. Frisbie, vice-president, both of Jackson.

NORTHVILLE.—The Common Council is stated to have granted a franchise to C. A. Ward, of Ann Arbor, for furnishing electricity for lighting the streets and residences and power for factories in the town. The franchise is for 30 years and carries with it a 10-year contract to supply the village and private consumers. The company will develop its electricity near Hamburg, on the Huron River, where it will build three dams. Generators will be placed at each dam, and the electricity transmitted to Northville, South Lyon, Ypsilanti, Ann Arbor and other points.

GRAND RAPIDS.—Articles of association have been filed by the Grand Rapids-Muskegon Water Power Electric Company, with a capital of $1,000,000, to build one or more dams on Muskegon River, to convert water power into electrical current and to deliver this for commercial purposes in Grand Rapids, Muskegon, Big Rapids and other places. The first dam will be built at Rogers' Bridge, about 6 miles below Big Rapids. The directors are: Thomas Huma and David D. Erwin, of Muskegon; W. A. Foote, of Jackson; John E. Moro, of Grand Rapids, and others.

ALPENA.—A deal is reported to have been closed by which Frank W. Fletcher, George P. Smith and other capitalists secure control of the Alpena Electric Light Company, the Alpena Water Company and the Thunder Bay Boom Company. These companies will be merged into a new company, to be known as the Alpena Power Company, with a capital of $500,000. The new company controls all the water privileges of Thunder Bay River, and is organized for the purpose of supplying electric power to Alpena manufacturers, as well as continuing the business of the old companies. Hubbard Lake will be raised 6 ft., thus largely increasing the water power of the river.

MINNESOTA.

EAGLE LAKE.—The City Council has under consideration the question of constructing either a gas or an electric light plant.

BECKEE.—Reports state that an electric light plant is to be established here, but none of the details of the project have been given out.

DULUTH.—The Great Northern Power Company is now prepared to develop the large water power of the St. Louis River. The National Railway Contracting Company, of Boston, has been awarded the contract for the development work, including the construction of the power canal. The enterprise is being financed by Tucker, Anthony & Co., of Boston, and Charles D. Barney & Co., of New York and Philadelphia. The company is capitalized at $8,000,000. C. A. Duncan is president of the company, and Francis A. Cokefair, chief engineer. The power plans call for an initial development of 30,000 horse-power, which will later be increased to possibly 200,000 horse-power. Five hundred men will be employed upon the work, which is to begin this winter. The Duluth-Superior Traction Company is said to have contracted already for a maximum of 10,000 horse-power to operate its system.

MISSISSIPPI.

YAZOO CITY.—The Yazoo City new electric lighting plant was put in operation recently.

McCOMB.—The McComb City Electric Light & Power Company has been incorporated with a capital of $50,000.

ABERDEEN.—Bonds to the amount of $80,000 have been authorized by the City Council for the construction of an electric light plant and a system of water works and sewers.

MISSOURI.

POPLAR BLUFF.—Reports state that Bacon, Hays & Wilkey have purchased the business of the Hartzell Light & Milling Company.

TRENTON.—Part of the plant of the Trenton Gas, Light & Power Company has been destroyed by fire, but the damage to the machinery is said to have been slight.

VERSAILLES.—The City Council has accepted the electric light plant from the St. Louis contractors. The plant is owned and operated by the city and was built with the proceeds from the sale of $10,000 in bonds.

MARCELINE.—Early & Callahan, proprietors of the local electric light plant, are extending their lines to include the new portions of the city, which involves the stringing of several miles of wire and the erection of new poles.

STANBERRY.—The Stanberry Electric Light Company is making arrangements to operate a day circuit, beginning about April 1 of this year. The company is also contemplating putting in a steam plant. Another engine of the Corliss type, direct-connected to a 75-kw. generator, has been recently installed in the present plant.

STURGEON.—The Board of Aldermen has appointed a committee, consisting of W. S. Harris, J. W. Hulett, O. D. Gray and O. I. King, to visit various Missouri cities for the purpose of investigating the cost of installing and maintaining a muncipal electric light plant. Upon receipt of the committee's report, the advisability of bonding Sturgeon for a sufficient amount to install the plant will be considered.

ST. LOUIS.—Another reduction in the cost of lighting the city institutions by the municipal lighting plant is contained in the report of the chief engineer to the president of the Board of Public Improvements. The reduction becomes plain when it is considered that less than four years ago the city was paying 13½ and then 7½ cents per kilowatt-hour for light, and is now paying more than 5 per cent. for light to other city buildings. The engineer's report for the month of December states that the city is receiving the same light at the rate of 1.058 cents. In this way the engineer who devised the plant and installed it in the new City Hall has notified the Board of Public Improvements that the plant, which cost $35,000, will have paid for itself in less than a year out of the difference in the cost of light. The president is sanguine of the installation of the new central lighting and heating station to supply the House of Refuge, Poorhouse, Insane Asylum and Female Hospital on which site the new City Hospital is now being erected. Friends of municipal ownership are enthusiastic over the showing of the lighting plant.

MONTANA.

BOZEMAN.—The Gallatin Light, Power & Railway Company is expecting to either remodel its steam plant or install a large water power plant during the coming summer.

NEBRASKA.

GERING.—G. L. Shumway has organized a company, known as the Pathfinder Electric & Water Power Company, which purposes building an $85,000 power plant, with a capacity of 400 horse-power, on the North Platte River, near Gering. It will be necessary to construct a ditch four miles long to conduct the water to the proposed site.

NEVADA.

RENO.—The Washoe Power & Development Company's electric plant is rapidly nearing completion and the management expects to be furnishing power for electric lighting and other purposes within the next three or four months.

NEW HAMPSHIRE.

LACONIA.—Allen A. Tirrill, of Schenectady, N. Y., is said to be interested in the construction of an electric power station on Pemigawassett River, near Franklin, this State. The current will be transmitted to this city for lighting and power purposes. Mr. Tirrill is also reported to have secured an option on the local electric light plant.

NEW JERSEY.

ASBURY PARK.—The Council has granted a franchise to Jesse W. Starr for a gas and electric light plant.

BORDENTOWN.—The Bordentown Electric Light & Motor Company is changing its lighting system from direct to alternating current, both for public and private lighting.

HAMMONTON.—H. E. Woodman, C. E. Starr and F. P. Reed have filed articles of incorporation for the Hammonton Electric Light Company, fixing the capital stock at $50,000.

PERTH AMBOY.—Peter Floersch, Kelly & McAlinden, Sickles Brothers, and other merchants of this town, are said to be interested in the organization of a company to construct an electric light plant.

BAYONNE.—It seems likely that Bayonne will eventually erect and operate its own electric lighting plant. Mayor Brady favors the enterprise, and it is believed that the question will be seriously considered, as the present contract expires soon.

PITMAN GROVE.—The plant of the Pitman, Clayton & Glassboro Electric Light Company has been sold to M. K. Treichler, of Philadelphia, for $20,000. The plant is a valuable one, with franchises for lighting several towns in the vicinity.

KEARNY.—The Council has passed a resolution, after rejecting all bids for lighting the town, providing for the construction of a municipal electric light plant and authorizing the Lighting Committee to engage an engineer to prepare complete plans and specifications for such a plant.

JERSEY CITY.—The North Jersey Electric Heat, Light & Power Company, recently incorporated, has elected officers as follows: President, Thomas J. Malone; vice-president, Michael T. Connolly; secretary and treasurer, Christopher P. Smith. Other directors are William J. Dynan and Charles Wagner. It is understood that the organization is entirely independent of all other electric light companies, and it is proposed to begin operations in the spring in territory in which electric lighting is practically undeveloped.

NEW MEXICO.

GALLUP.—Reports state that George Page has succeeded to all the stock and business of the Gallup Electric Light & Power Company.

NEW YORK.

COHOES.—Plans are being prepared for increasing the capacity of the local lighting plant.

ONEIDA.—De Witt C. Hadcock, of this city, states in regard to the Limekiln Falls water power, that contracts will not be let until April 1.

ROCHESTER.—The Denio General Electric Company has been incorporated with a capital of $200,000. H. F. Atkinson and G. W. Ham are among the directors.

LOCKPORT.—The American District Steam Company has petitioned the Council for a franchise for the transmission of electricity for lighting, heating and power purposes.

FORT PLAIN.—The Fort Plain Gas & Electric Light, Heat & Power Company has secured the contract for lighting the town for five years more at the rate of $60 per light per year.

BATAVIA.—The incorporation of the Batavia Light & Power Company Company, with a capital of $10,000, is reported. Seth W. Warren and George R. Howard are among the incorporators.

CANAJOHARIE.—The Montgomery Electric Light & Power Company is considering the installation of an auxiliary steam plant with a capacity of 250 horse-power, as a reserve in case of an accident to the water plant.

PALMYRA.—William T. Morris, of Penn Yan, who recently purchased the gas plant at Lyons, has bought the electric light plant of this city, which was owned by O. J. Garlock, president of the Garlock Packing Company. It is said the plant cost $35,000 when it was installed.

NEW YORK CITY.—The Manhattan & Bronx Electric Company, with a capital of $10,000, has been incorporated for the manufacture of electricity to supply light, heat and power in the boroughs of Manhattan, Bronx, Brooklyn, Queens and Richmond. The directors are Willis B. Richards, John S. Clark and James C. Stratford.

OSWEGO.—The People's Gas & Electric Company has secured the contract for lighting the city for a term of five years at $66 per arc light per year and $3.65 per year for incandescent lights. As there are 261 arc lamps distributed about the city and 259 incandescent lights used in the public buildings, etc., the total amount covered by the contract is $18,171.35 per year for all-night service.

ALEXANDRIA BAY.—The St. Lawrence International Railroad & Land Company is steadily improving its water power development and expects soon to be prepared to furnish light to Redwood, a small town about seven miles distant. The company expresses itself as well pleased with the success of its railroad and lighting systems during the past year.

BROOKLYN.—The past year has been one of marked development for the Edison Electric Illuminating Company, of Brooklyn. There has been a large increase in the business of the company during the year, amounting to over 20 per cent. The company has spent about $2,000,000 in improvements in the last two years, and preparations are now being made at the Gold Street waterside station for the arrival and installation of a 10,000-h.p. turbine and generator having a capacity of 7500 kilowatts.

NEW YORK CITY.—The New York Edison Company has secured the contract to supply the entire service for the new Hippodrome which is being erected on Sixth Avenue, between Forty-third and Forty-fourth Streets. There will be 17,800 incandescent lamps and something more than 200 horse-power in motors. The facade is to be outlined in incandescent lamps, and large signs are to bring forcibly to the attention of the passing public the purpose of the building and the attraction for the time being presented. The New York Edison Company and the Edison Electric Illuminating Company of Brooklyn were the only bidders for the lighting of the Brooklyn Bridge. The contract was divided, one-half going to Manhattan and the other to Brooklyn. The bids were $130 a lamp a year for the 2000-c.p. arc lights and $18 for incandescent lights.

NEW YORK CITY.—The Board of Estimate has adopted a resolution appointing a commission to prepare general plans and specifications for, together with an estimate of the cost of, a municipal electric light plant for New York City. The commissioners will be Nelson P. Lewis, chief engineer of the Board; Prof. George C. Sever, of Columbia University, and Cary T. Hutchinson, consulting electrical engineer. The utilization of the city's waste for boiler purposes will be considered. Comptroller Edward M. Grout has been investigating the cost of gas and electric lighting as supplied to the city at present, in which work he was assisted by Mr. Edward B. Ellicott, city electrician of Chicago. Much objection to the proposition of establishing a city plant is being organized, and Lighting Commissioner Oakley maintains that the figures relating to the comparative cost of lighting in other cities refer to so many differing conditions that it is not fair to base any conclusions upon them.

NORTH CAROLINA.

ASHEBORO.—The Asheboro Electric Company has been incorporated by A. M. Rankin, W. M. C. Hammer, W. J. Miller and others. The company will construct and operate an electric light and power plant in Asheboro. It is capitalized at $50,000.

CHARLOTTE.—The Factory Site & Power Company, which was incorporated at Waynesville lately, with a capital of $300,000, is now transmitting 500 horse-power of electricity and will soon have 1500 horse-power more for the use of cotton mills and other factories in its neighborhood.

SOUTHERN PINES.—R. L. Chandler, proprietor of the R. L. Chandler Electric Light Plant, writes that he is in the market for a good new or second-hand engine suitable to run an electric light plant of about 80 or 100 horse-power capacity. He also expects to be in the market soon for an alternating-current generator.

ROCKINGHAM.—The water power at Bluett's Falls on the Pee Dee River, about eight miles from this place, is soon to be developed. Negotiations, which have been pending for more than a year, have culminated in the taking over of a number of options by Hugh McRae & Company, bankers, of Wilmington, involving the expenditure of about $120,000 for the rights on both sides of the river. It is thought that 30,000 horse-power can be developed, which will be distributed to points within a radius of twenty or thirty miles. The work will be commenced at an early date, either by McRae & Company or by a corporation organized by them for the purpose.

OHIO.

CAMDEN.—The Camden electric light plant has been sold to E. C. Eickenberry for $3000.

MIAMISBURG.—An issue of $19,000 bonds has been authorized by the village to be used for enlarging and improving the electric light plant.

WARREN.—The Phoenix Electric Company, with a capital of $5000, has been incorporated by W. A. Smith, Glen C. Webster, Edwin O. Izant and others.

MT. VERNON.—Mr. Hubbell and others have been granted a franchise for an electric light plant, which will be constructed and operated under the name of the Citizens' Electric Company.

DILLONVALE.—William B. Dager, Frank Alexander and others have filed articles of incorporation for the Dillonvale Heat, Light & Power Company, with a capital of $50,000.

TOLEDO.—The Toledo Heating & Light Company is contemplating extensions and improvements this coming spring, which will probably include the substitution of alternating for direct current in its lighting circuits.

CINCINNATI.—Local press reports state that the Cincinnati Gas & Electric Company will expend, in the near future, about $500,000 in the West End and about $200,000 in the East End in extending and improving its service.

CLEVELAND.—The Cleveland Electric Illuminating Company, in bidding for the work of furnishing arc street lamps to Cleveland for 1905, lowered its price $1.44 per lamp a year. At present the city is paying $75 per lamp a year for arc lights. The new bid of the company is $73.56 per lamp. Since Cleveland has 1211 lamps the lower price means a saving of $1,743.84 a year.

YOUNGSTOWN.—J. H. Perkins, general superintendent of the Youngstown Consolidated Gas & Electric Light Company, has resigned that position to become general manager of the Wilkesbarre Gas & Electric Company, Wilkesbarre, Pa. Alexander Webb, of New York, has been elected treasurer of the Youngstown Company to succeed Mr. L. C. Root, who resigned recently.

BARBERTON.—A new electric lighting plant may be installed in Barberton in a short time. The Barberton Inn owners, O. C. Barber, of Akron, and M. J. Alexander, of Pittsburg, hold a franchise granted them about a year ago by the Council which gives them the right to install an electric lighting plant and to wire the city. The plant of the Barberton Inn, which furnishes all the light for the big hostelry, is now being run at only an eighth of its capacity, and it could alone furnish electricity for lighting the downtown section of the town. The plan is to install a bigger plant at the Inn and to compete with the Northern Ohio Traction & Light Company.

OKLAHOMA TERRITORY.

SHAWNEE.—The Shawnee Light & Power Company is making extensions to its system in order to keep pace with the demands for service.

GUTHRIE.—The Guthrie Electric Light & Power Company, which was recently incorporated at $150,000, has increased its capital stock from that amount to $250,000.

OREGON.

COQUILLE.—Manager Frank Moore, of the Coquille Electric Company, will improve the present property by the installation of new boilers and the erection of a 25 x 100-ft. storage house.

THE DALLES.—The power plant of The Dalles Electric Light Company will soon undergo extensive improvements. Manager J. G. Van Orsdale states that a larger engine will be installed and new dynamos added.

FOREST GROVE.—The interests of E. W. Haines and others in the electric light plant of this place have been taken over by the Haines Electric Power Company. E. W. Haines, John Thornburg, C. W. Nottingham and J. Frank Watson are the incorporators. The company is capitalized at $50,000.

HOOD RIVER.—The board of directors of the Hood River Electric Light, Power & Water Company has authorized an issue of $100,000 in bonds which will be used in making extensive improvements in the service. H. F. Davidson has been elected president and general manager of the company, H. L. Vorse having resigned.

OREGON CITY.—The Portland General Electric Company, of which H. W. Goode is president, is preparing plans for the construction of a 40,000-h.p. electric plant at Willamette Falls, near this city. When the undertaking is carried into effect the company will have facilities for generating a total of 52,000 horse-power at the Oregon City plants and a duplicate steam plant in Portland. The new power station is to be built on the east side of the river and will be so constructed that any needed amount of power can be developed by adding units to meet the demands. The first installation at the new station will probably be three units, or 10,500 horse-power. Additional units of 3500 horse-power will be installed as rapidly as the demand for electric light and power develops. For every unit installed at the Oregon City plant a unit will be added to the steam plant in Portland. The building of a duplicate plant to be operated by steam is for the purpose of providing power to be used during the low water period each year and to avoid a possibility of having the service crippled by accident. The company intends to be in a position to furnish power and light not only to Portland but to any of the towns in the Willamette valley, and to meet the needs of the rapidly multiplying manufacturing industries in this territory.

PENNSYLVANIA.

STATE COLLEGE.—The Nitanny Light, Heat & Power Company has been incorporated with a capital of $10,000.

YOE.—The Yoe Electric Light Company has filed articles of incorporation stating its capital stock to be $5000.

CARBONDALE.—The Hendrick Light & Power Company has petitioned for a franchise for an electric light plant.

MAHANOY.—The Mahanoy City Light, Heat & Power Company has sold its entire plant to the Shenandoah Electric Illuminating Company.

YORK.—The Edison Electric Light Company is equipping an auxiliary plant for use at such times as high water and ice may impair the efficiency of the power plant at York Haven.

PITTSBURG.—The Committee on Public Works has recommended an ordinance authorizing the letting of the contract for lighting the city for one year at a cost not to exceed $400,000.

WEST CHESTER.—The Council has passed a resolution renewing the contract with the Edison Electric Illuminating Company for lighting the streets for the next five years at $10,000 per year.

TAMAQUA.—The Town Council has awarded to John F. McGinty and E. M. Sharp the contract for lighting the town for a period of ten years at $60 per light per year. They will commence constructing their plant in the spring and will be ready to take up their contract on January 1, 1906.

CHAMBERSBURG.—At a special meeting of the Borough Council, Burgess Sharpe submitted a message vetoing the ordinance authorizing the sale of the Chambersburg light plant to the Chambersburg Light, Heat & Power Company. The chief reason given for the veto is that the price is inadequate.

EASTON.—Bayard G. Eckard has been appointed superintendent of the Easton municipal electric light plant. Mr. Eckard is a graduate of Lafayette College, and at the time of his appointment was in the New York office of the Westinghouse Electric & Manufacturing Company.

PLYMOUTH.—This city has been selected as headquarters for the new light company which recently acquired control of the plants at Nanticoke, Plymouth, Edwardsville, Kingston, Luzerne, Dorranceton and Forty Fort. C. A. Geist and Charles B. Kelsey, who are at the head of the new combine, promise many improvements.

YORK HAVEN.—The York Haven Light & Power Company has procured a 60-day option on the plant of the Steelton Heat & Electric Light Company, which furnishes light and heat to the borough of Steelton and the adjoining town of Oberlin. If the deal for the Steelton plant is finally consummated, it is proposed to furnish its power from the York Haven plant.

PHILADELPHIA.—The Commonwealth Electric Company has been incorporated with a capital of $100,000, wih the expectation of supplying electricity for lighting, heating and power purposes. The incorporators are Mark Hyman, New York; Ross A. Mackey, Brooklyn; Herbert Scovill, New York; Graham Sumner, Englewood, N. J.; . D. Oakford, John M. Ingham and William M. Clift, Philadelphia. Mr. Hyman is president of the corporation.

ELLWOOD CITY.—The Ellwood Power Company has been taken over by a larger corporation, recently organized under the name of the Pennsylvania Power Company. The incorporators are ... L. Smith, A. J. Barron and B. R. Thomas, all of Pittsburg. The new company expects to put in one or more new dams and to go forward with the development of the water power at Ellwood City. The transmission line is completed to West Pittsburg.

CATASAUQUA.—W. W. McKee, receiver of the Lehigh-Northampton Gas & Electric Company, has been authorized by the Lehigh County Court to issue certificates to the amount of $65,000, the proceeds of which will be used to modernize and enlarge the plants of the company. A direct-connected engine-generator unit and a new Sterling boiler will be installed and all the lines placed in first-class condition. The company now furnishes light in this city, Hokendauqua, Coplay, Cementon, Siegfried and Northampton.

HANOVER.—J. W. Mumper, a local electrician, has been awarded the contract for lighting the streets of this town. The other competitors were the Hanover Light, Heat & Power Company and the Welsbach Company, of Philadelphia. The Hanover Light, Heat & Power Company offered to light the streets from dusk until midnight for $60 per light; the Welsbach people offered their gas lamps on an all-night service for $35 per lamp, while the Mumper bid was for 2000-c.p. electric lights on an all-night service at $64.92, provided he be given a ten-year contract. The Borough Council decided this was the lowest bid and a formal motion was adopted that a contract be entered into with Mr. Mumpher. He will be required to give a bond in the sum of $5000 for the faithful performance of his side of the agreement.

SOUTH CAROLINA.

SUMTER.—The Sumter Light & Railroad Company has secured a franchise for an electric light plant.

LEXINGTON.—Samuel B. George and Julian E. Kaufmann are interested in the construction of an electric light plant, but it is understood that no engineer has been engaged as yet.

CLINTON.—Engineer Charles C. Wilson writes that bids will be received February 15 for the construction of water works and an electric light plant for Clinton. The cost of the plant is estimated at $25,000.

COLUMBIA.—The Columbia Electric Street Railway, Light & Power Company has secured the contract for lighting the city for five years. The contract provides for about 200 lights of 1200 candle-power at $65 per light per year, the lamps to be lighted from 30 minutes after sunset until one hour before sunrise.

SOUTH DAKOTA.

HURON.—E. G. Bowe, proprietor of The Electric Company, writes that it is proposed to install another alternator and engine next season. An additional boiler was recently put in, and it is

intended to increase the capacity of the plant as rapidly as additional demands upon its service require it.

DEADWOOD.—The properties of the Black Hills Electric Light Company, of this city, and the Belt Light & Power Company, of Lead, have been purchased by a new company to be known as the Black Hills Consolidated Electric Light & Power Company, the negotiations for the transfer having been conducted by J. J. Henry, of Denver. It is understood that Harris Franklin and others of this city are assisting to finance the deal. The new company expects to spend a quarter of a million dollars in enlarging and improving the plants now under its control and is planning to furnish electric power to the various mining companies of the northern Hills. The price per horse-power has been reduced, so that it will be cheaper than steam power.

TENNESSEE.

COOKEVILLE.—Bonds to the amount of $25,000 are being issued by the city, the proceeds of which will be invested in an electric light plant and its equipment.

KNOXVILLE.—A bill is to be introduced at the next Legislature, asking for authority to issue $200,000 bonds for the purpose of constructing a municipal electric light plant.

JEFFERSON CITY.—The Jefferson City Electric Company's plant was recently destroyed by fire, entailing a loss of $4000. The company is preparing to rebuild the plant.

TULLAHOMA.—The municipal electric light and water works plant is in the market for a 150-h.p. gas engine and gas producer plant. C. W. Lytle is superintendent, and all communications in reference to the matter should be addressed to him.

MEMPHIS.—A concern known as the Merchants' Power Company has been organized, with a capital of $500,000, to construct and equip a plant to supply private consumers. A plant is also to be built to supply the city, it is said, and the city will have the option of buying either or both of the plants.

KNOXVILLE.—Mr. P. E. Mitchell, who has been acting as superintendent for some months past, has been appointed general superintendent of the Knoxville Electric Light & Power Company to succeed Mr. W. C. Woolfolk, who has resigned. Mr. Mitchell will have general supervision of both railway and lighting departments.

TEXAS.

BAIRD.—The Baird Electric Company is said to have closed its plant in this city.

DALLAS.—The Dallas Electric Light & Power Company contemplates building a new power house.

CORPUS CHRISTI.—The Corpus Christi Electric Light & Power Company is giving its plant a thorough overhauling, which amounts practically to rebuilding it.

GONZALES.—W. L. Gardien, treasurer and manager of the Citizens' Electric Light & Power Company, has resigned his position and sold his interest in the company to Thomas H. Spooner.

ROYSE.—Articles of incorporation, fixing its capital stock at $20,000, have been filed by the Royse Milling & Lighting Company, of this city. J. E. and C. E. Paynter are among the incorporators.

GRANDVIEW.—A concern, to be known as the Grandview Mills, Light & Ice Company, has been incorporated by W. B. Head, R. E. Pitts, T. E. Pittman and others. The company's capital is placed at $20,000, and it is proposed to operate a corn mill, ice factory and electric light plant.

MINERAL WELLS.—Articles of incorporation have been filed by the Mineral Wells Electric Light, Power & Heating Company, which is capitalized at $50,000. V. E. Lycan, of Edna, Mo.; D. G. Galbraith and William D. Williams, of Fort Worth, are the incorporators of the new concern.

SHERMAN.—The Sherman Gas & Electric Company has in operation a plant which is an interesting one for one of its size. Two 250-h.p. Diesel engines are connected to two 160-kw. 250-volt direct-current generators. The generators supply circuits operated on the three-wire system, the system being balanced by means of two independent equalizing sets, each of the sets consisting of two 10-h.p. motors coupled together. Alternating current is also supplied for lighting the outlying districts by means of a 60-kw. alternator direct-connected to a motor which in turn receives its current from one of the generators mentioned above. R. B. Stichter, general superintendent, states that the plant has been in operation for some weeks now and is working very satisfactorily.

UTAH.

PAYSON.—It is proposed to bond the city for $12,000 for improvements to its electric light plant.

AMERICAN FORK.—J. H. Wooten, manager of the Utah County Light & Power Company, has prepared plans for the erection of the proposed light and power plant in American Fork canyon. It will be a combined hydraulic and steam plant and its cost is estimated at about $400,000.

VERMONT.

RUTLAND.—The principal contracts for the equipment of the Chittenden Power Company's hydraulic plant near Rutland have just been determined upon by J. G. White & Company, who have secured the complete contract for the construction and equipment of the plant. The initial installation will have a capacity of 1200-kw. There will be three 400-kw. generators for direct connection to McCormick turbines of 770-h.p. capacity each. The General Electric Company has taken the order for the equipment to be installed in the sub-stations, consisting of three 150-kw. rotary converters. The turbines will operate on a head of 215 feet. Considerable construction work has already been completed on the Chittenden project. Large dams and reservoirs have been built, also a 5-ft. steel conduit 8000 feet long, running from the dam to the site of the power house. The energy will be transmitted to Rutland for general uses. The transmission line will be about seven miles in length. It will operate at 13,000 volts.

VIRGINIA.

NORFOLK.—The Norfolk Railway & Light Company is installing a 1500-kw. Curtis turbine unit to operate on a 2300-volt three-phase alternating-current circuit.

NORFOLK.—Mr. Thomas J. Gates has been appointed assistant city electrician after a competitive examination in which he was successful over seven other candidates.

MARTINSVILLE.—Bonds to the amount of $60,000 have been voted for the improvement of the water power on Smith River to furnish lighting and power current to the town. Half of the issue voted for has already been sold and work on the new plant will begin shortly.

RICHMOND.—Mr. S. C. Midberry, electrician at the Virginia Passenger & Power Company's plant, has resigned to take up new work in New York City. Mr. Midberry was presented with a handsome seal ring by his associates. He is a graduate of Union Polytechnic Institute and the students' course at the General Electric Company's works, Schenectady.

WASHINGTON.

MILTON.—The citizens have voted for a bond issue of $15,000 to establish an electric light and power plant.

SPOKANE.—The Wallace Light & Heating Company, with a capital of $25,000 has filed articles of incorporation.

SPOKANE.—C. C. Van Inwegin, Jr., has sold his interest in the Citizens' Electric Light Company to M. S. Gardner.

DAVENPORT.—John Riley and F. H. Springer have succeeded to the electric light plant of the Davenport Machinery Company.

SEATTLE.—The Seattle Electric Company has petitioned for a franchise to furnish electric light to Renton, a suburb of this city.

BALLARD.—The City Council has granted to L. V. Brewer a franchise to furnish light and power in the city for fifty years.

SEATTLE.—The Seattle Lighting Company has completed its plans for new sub-station buildings and work will be commenced soon.

REARDAN.—J. M. McDowell, of Deer Park, has made application for a franchise to construct and maintain an electric light plant here.

SPOKANE.—General Manager D. L. Huntington, of the Washington Power ompany, states that extensive improvements will be made on the Spokane plant.

ABERDEEN.—The Ninemire & Morgan Company has petitioned for a franchise for an electric light and steam heating plant, the franchise to run fifteen years.

NORTH YAKIMA.—A thirty-year franchise has been granted to the Northwest Water & Light Company. A new system is to be put in by the company and water will be brought ten miles up Naches River.

TACOMA.—The Seattle-Tacoma Power Company's new machinery is in transit. This machinery was ordered for the purpose of doubling the capacity of the Snoqualmie plant. The work preliminary to placing the new unit in position is well in hand.

SPOKANE.—C. A. Luceford, of Davenport, says that the $3,000,000 with which to build the 213-mile electric system through Adams County has been subscribed. Power will be developed at the Narrows near the mouth of the Spokane River. The plant will cost $540,000. W. W. King, of Ritzville, is secretary of the company.

WEST VIRGINIA.

GRAFTON.—A new company has been incorporated, by the name of the Grafton Railway & Light Company, capitalized at $400,000. The company will construct and operate an electric railway and an electric light and power plant in Grafton.

BENWOOD.—The Benwood & McMechen Electric Light Company and the Home Electric Company, of McMechen, have been consolidated and the Ohio Valley Electric Light Company of Benwood and McMechen will begin its existence as an incorporated concern. The articles of incorporation filed by the company state its capital stock to be $50,000, the incorporators being W. H. Snyder, Charles Schad, Robert Newton, of Benwood, and S. E. Dorsey, of McMechen.

WISCONSIN.

RACINE.—A proposition is being agitated here for a municipal electric light plant.

JANESVILLE.—The National Light, Fuel & Gas Company has been incorporated with a capital of $5000.

ALBANY.—Warren & Tompkins, owners of the local electric light plant are making extensions to their system.

OSHKOSH.—The Central Construction Company may apply for a lighting and power franchise here, it is said.

SHEBOYGAN.—Frederick Karste has resigned the presidency of the Sheboygan Light, Power & Railway Company.

MADISON.—The Madison Gas & Electric Company has installed a 600-h.p. Westinghouse steam turbine at its power house.

CAMPBELLSPORT.—The Dundee Water Power & Electric Light Company has recently added an arc circuit to its system.

AMERY.—The Amery Electric Company is extending its commercial lighting circuits and adding a dynamo to its equipment.

MILWAUKEE.—The Milwaukee Electric Railway & Light Company's plant has been damaged by fire to the extent of $5000.

MAYVILLE.—The F. Paustian Milling Company has recently installed in its lighting plant a new boiler, new engines and a new generator.

MANITOWOC.—The Common Council has ordered the city engineer to prepare estimates of the cost of erecting a municipal lighting plant.

SHAWANO.—The managers of the municipal lighting plant are changing the city arc light system from direct current to series alternating current.

CASSVILLE.—It has been voted by the citizens to install an electric light plant. The contract has been let to the Galena Iron Works at $4310.

PLATTEVILLE.—The Platteville Light & Power Company will probably increase both its steam and electrical equipment this year, as both have reached the limit of their capacity.

WATERLOO.—Alexander Archie, E. J. Rood, and others have incorporated the Consolidated Electric Light Company, having a capital stock of $75,000. Mr. Archie is president of the new concern.

MILWAUKEE.—Press reports state that in the budget for 1905 a provision of $400,000 is made for a municipal lighting plant, and it is understood that plans for the building have been filed with the building inspector.

MANITOWOC.—The West Side Electric Company, recently granted a franchise, will at once begin work on the erection of a $200,000 electric plant for furnishing power and heat. Ex-Mayor William Rahr is at the head of the enterprise.

CANADA.

ALVISTON, ONT.—The Alviston Power Company, Ltd., is extending its circuits to provide for about 300 more private lights.

ST. THOMAS, ONT.—Bids will be received February 15 by S. O. Perry, city treasurer, for $200,000 gas and electric light bonds.

CALGARY, N. W. T.—The ratepayers of Calgary have decided in favor of installing a municipal electric lighting system in the town.

CAMPBELLFORD, ONT.—It is proposed to install at the city electric light plant two direct-connected units of 800 kilowatts capacity each.

THOROLD, ONT.—It is proposed to substitute alternating-current series arc lamps for the direct-current lamps now used for lighting the city streets.

OSHAWA, ONT.—The Oshawa Electric Light Company is extending its street lighting circuits and also arranging to increase its service to private consumers.

PETROLIA, ONT.—The Petrolia Electric Light, Heat & Power Company is installing a new street lighting system of alternating-current series enclosed arc lamps.

STRATHROY, ONT.—A new engine room is being built at the municipal electric light plant, and upon its completion a new engine and condenser will be installed.

OTTAWA, ONT.—Application will be made to the Dominion Parliament at its coming session by the Niagara-Welland Power Company for an act authorizing the company to use its proposed canal for navigation purposes, to construct a tramway along its right of way, and to extend the time for the completion of its works.

TORONTO, ONT.—The Ontario Power Company has closed a contract with the Westinghouse Electric & Manufacturing Company for an alternating-current generator with a rated output of 10,000 horse-power at 85 per cent. power factor, designed for direct connection to water wheels. It generates three-phase current at 12,000 volts and 25 cycles and runs at a speed of 187.5 r.p.m. Among other apparatus included in the contract were twelve 3000-kw. oil-insulated water-cooled transformers wound for 12,000 and 60,000 volts; two 375-kw. exciters, and complete switchboards.

HAMILTON, ONT.—The Hamilton Cataract Power, Light & Traction Company has recently started the two 5000-kw. Westinghouse generators in its De Cew Falls power station in Ontario. Power is supplied from Welland canal feeders, tapped in about 14 miles above the power station, and at the station the water has a head of 267 feet. The Westinghouse generators are of the two-bearing type, direct connected to Escher-Wyss water wheels, and run at a speed of 286 r.p.m. They generate three-phase current at a frequency of 66 cycles, and a pressure of 2400 volts. The power is transmitted to this city where it is used for lighting, street railway and manufacturing purposes. A reserve steam-driven station is located at Hamilton, which contains two 1000-kw. Westinghouse generators. The entire station and high-tension apparatus are of Westinghouse design. The company has two separate three-phase transmission lines to Hamilton, a distance of about 35 miles. The high-tension apparatus is designed for a pressure of 40,000 volts, but will be operated for a time at 20,000 volts. Mr. Wm. C. Hawkins is general manager of the Hamilton Company, and is also engineer in charge of the installation.

NIAGARA FALLS, ONT.—The Canadian Niagara Falls Power Company, which is owned by the Niagara Falls Power Company on the American side of the river, set in motion a short time ago two of its 10,000-h.p. turbines. The officers of the power company, the commissioners of the Niagara Falls Queen Victoria Park, and other guests were witnesses. The trial was a great success. These are the largest working turbines and dynamos in the world, and their successful operation marks an important era in electrical development. Francis Lynde Stetson, of New York, and President W. H. Beatty, of the Canadian company, turned on the power, and each unit under full power developed 12,000 volts, and ran without a hitch. At the beginning of the test President Beatty turned on the water for wheel No. 1. The wheel was allowed to reach its full speed of 250 revolutions a minute and then President Beatty threw the switch which placed the generators in action. Wheel No. 2 was thrown on and 20,000 horse-power was developed. The Canadian Niagara Power Company is the first Canadian company to harness Niagara. Five electrical units of 10,000 horse-power each are being installed and six more can be added. The turbines for each unit were designed and manufactured in Switzerland. Each is at the bottom of a pit and attached by a vertical shaft to a 10,000 horse-power generator. The water is led to the driving wheels by penstocks, each of which is ten feet in diameter. The water is discharged through a short tunnel which ends at the water's edge just below the Horseshoe Falls. The tunnel is driven through solid rock and is lined with brick. The Canadian power house is connected with the one on the American side by cables which are carried in conduits through Victoria Park and across the upper steel arch-bridge. The first power from the Canadian plant will be transmitted to Toronto for power and lighting. Much of the power generated at the Canadian plant, will, however, be at the disposal of American consumers. In building the plant it has been so arranged that machinery for developing 100,000 additional horse-power over the present limit, may be installed at any time.

MEXICO.

MALINALTANGO FALLS.—Maj. George B. Burbank and George Stuart Simons, of New York; A. S. Harvey, of Leadville, Col., and Philadelphia capitalists are interested in a project to establish a large electric light and power plant at the Falls near the City of Mexico. About 25,000 horse-power will be generated.

CHAPALA.—Carlos Navarro Mora has been granted a concession by the state government for the establishment of an electric light plant and textile mill at the town of Chapala. The concession specifies that work on the two plants must be commenced within six months, and grants an exemption from all state taxes for a period of ten years. The electric plant will furnish light for the streets of Chapala.

MEXICO CITY.—Mr. David Reyes Retana, of this city, is primarily interested in a concession which is being negotiated for with the Mexican Government looking to the establishment of a large hydro-electric plant on the River Mexcala, State of Guerrero. It is proposed to use at least 60,000 liters of water per second. Half the power to be developed is intended for lighting and manufacturing purposes and the rest for irrigation.

MEXICO CITY.—The Mexican Light & Power Company, Limited, has secured a new contract from the Federal Government of Mexico, for lighting the City of Mexico for a period of ten years. The new contract increases the number of arc lights to 1200 to burn 4000 hours annually. The annual sum to be paid the company by the Mexican authorities is $325,777. The old contract was undertaken by the Mexican Electrical Works, Limited, formerly owned by the Siemens & Halske Electric Company, which was purchased some time ago by the Mexican Light & Power Company. The company is authorized under the new contract to generate current from the old Siemens & Halske steam plant, or from its Necaxa hydraulic plant. Hugh L. Cooper, chief engineer and manager of construction of the company, which is building the 45,000-h.p. Nicaxa-Mexico City-El Oro power transmission system, has resigned his position in order to devote his entire attention to the installation of the Niagara Falls (Canadian side)-Toronto plant and other important projects in the United States and Canada. Before recommencing work, however, he will take a two-months trip to Europe. Mr. F. S. Pearson, vice-president and consulting expert of the Mexican Company, is now in the southern republic looking over the construction of the system.

The accompanying tables already appear on page 93 of this issue in connection with the article on "Changing Magnet Windings for Different Voltages" and are reproduced here for the convenience of those who might wish to cut them out without destroying any of the reading matter in the issue.

POWER AND LIGHTING EQUIPMENT OF A BROOKLYN MUSEUM

PLANT OF THE BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

BY E. T. WALSH.

The museum of the Brooklyn Institute of Arts and Sciences, located on Eastern Parkway, near Prospect Park when finished will be a large rectangular building 560 feet square, and having four interior open courts. The west wing has been in use for seven years, the central portion is ready for occupancy, and the east wing is now under process of construction.

Since the edifice was first started it has been the policy of the management to generate the electricity necessary for lighting and power service, and as a temporary expedient part of t'·e ground floor of the west wing was dev d to a power plant. The equipment consists of two Ideal engines, one of 125 horse-power and the other of 75 horse-power, which are direct-connected to compound-wound G. E. dynamos. Steam is supplied by two tubular boilers. The completion of the central portion of the museum increased the demand for power far beyond the capacity of this old plant, and the installation to be described was designed to supply the increased demand with a sufficient reserve to provide for future extensions.

The new plant is situated on what will be one of the open courts of the completed museum, and is connected with the main building by tunnels. It is a plain brick structure one story high, with a flat fireproof roof, water-proofed cement floors in the engine and pump rooms, and brick floors in the boiler room and coal vault.. It is well lighted and ventilated by windows generous in size and number. The

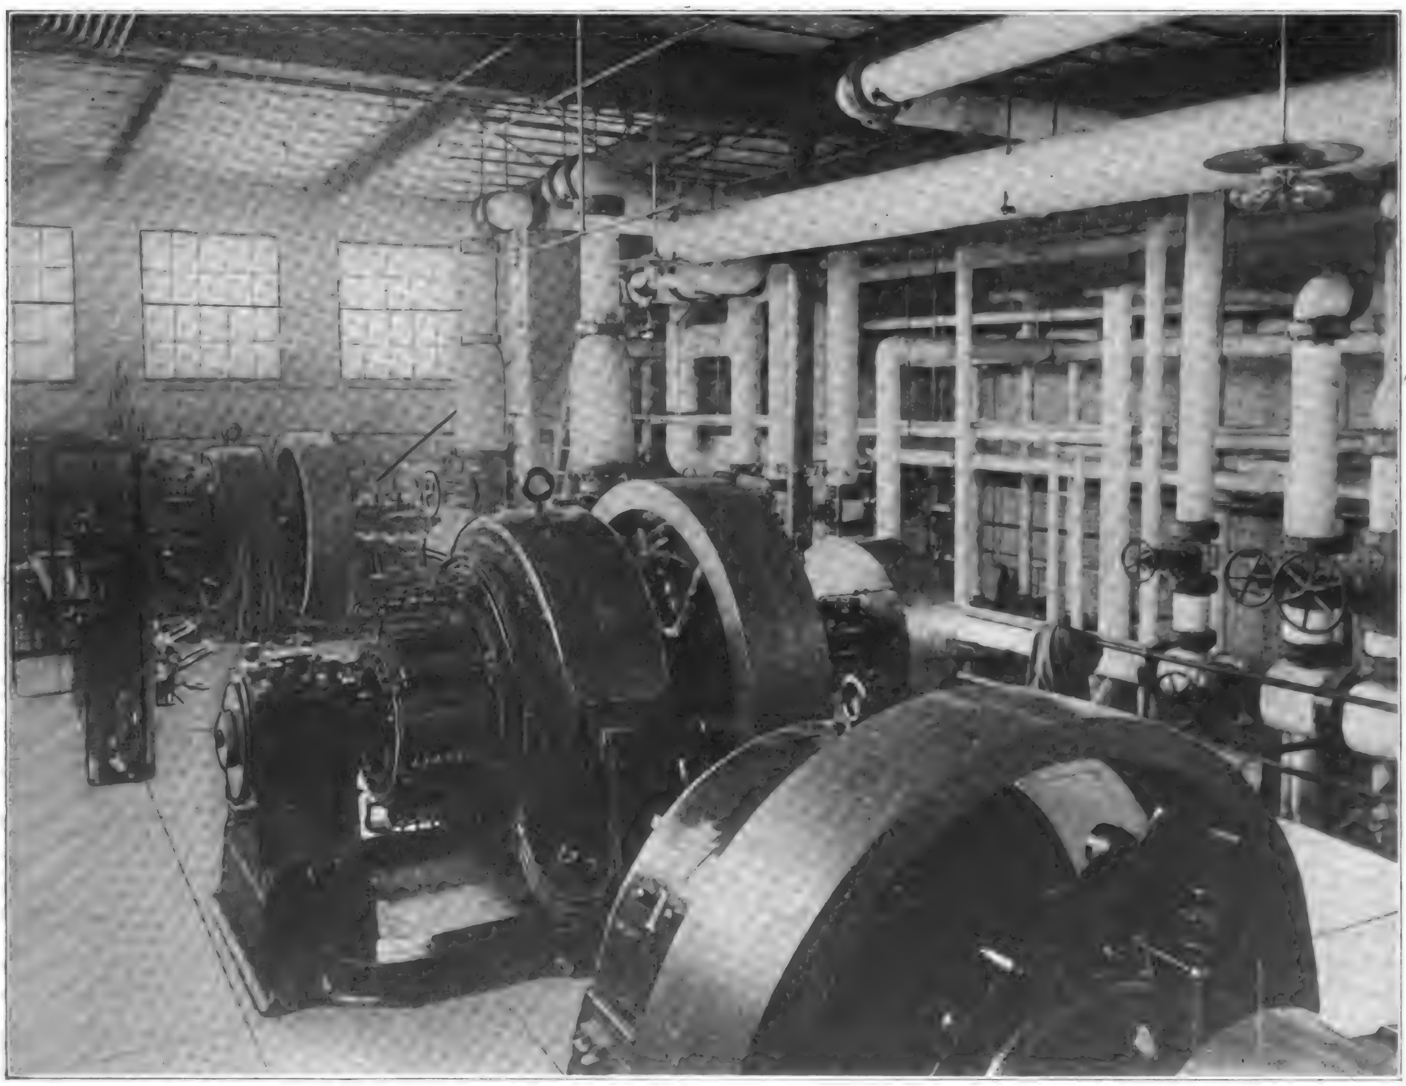

FIG. I.—ENGINE ROOM IN POWER AND LIGHTING PLANT OF THE BROOKLYN INSTITUTE OF ARTS AND SCIENCES.

main part is 84 feet 4 inches long by 52 feet wide, with an ell 14 feet wide by 24 feet 4½ inches long. The building is divided by a brick wall into a boiler and engine room. In one end of the boiler room are the coal bunkers and hydraulic elevator for removing the ashes. Part of the engine room is occupied by the pumps and auxiliaries, together with the steam and water piping. This portion of the room is on the same level with the boiler room. In the ell the chief operating engineer has his office, the floor of which is on the same level as the finished grade of court. At the opposite side of the engine room and on the same level as the office, is located a toilet room containing a closet and lavatory, with lockers for the engineer's assistants.

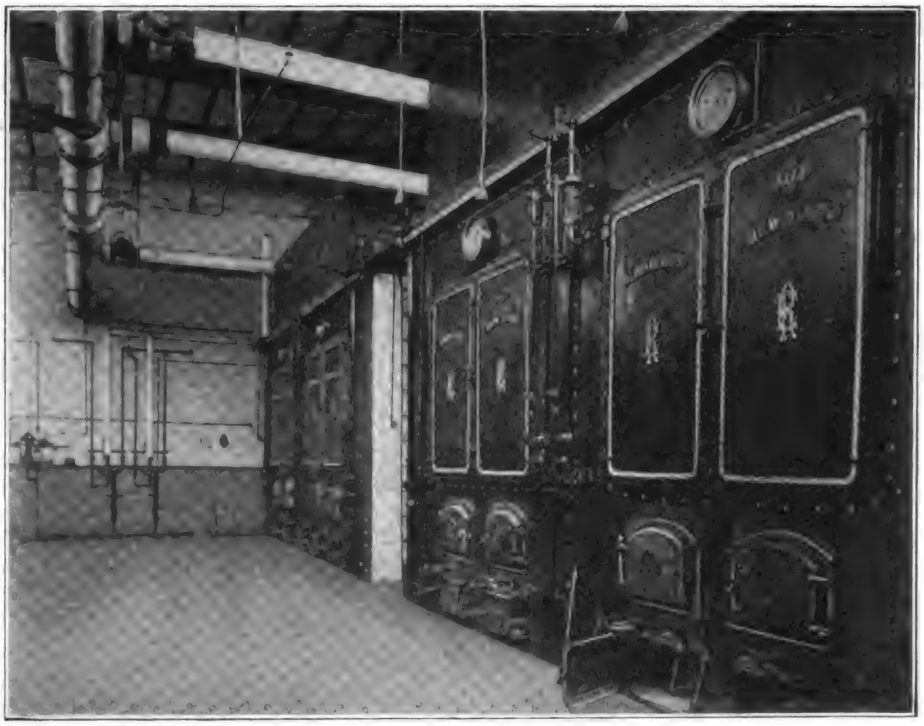

FIG. 2.—BOILER ROOM OF BROOKLYN INSTITUTE POWER PLANT.

Coal is delivered to the plant in carts and deposited in the vault through manholes. The capacity of the coal vault is 500 tons. The ashes are dumped from the grates into a pit and shoveled into barrows and wheeled to the hydraulic lift. The ashes are at present used for filling in purposes, but will ultimately be removed by cart.

There are four boilers of the horizontal return-tubular type in the boiler room, each 78 inches in diameter and 18 feet long, containing 120 American lap-welded tubes 3½ inches in diameter. Each is supplied with a dome 36 inches in diameter by 36 inches high, and has two manholes, one in the front heat under the tubes and the other in the top of the shell. There is also a handhole in the rear head under the tubes. The boilers are supported on heavy cast-iron lugs, eight to a boiler, which have an 18-inch bearing on the wall and 16 inches on the boiler shell, being connected thereto by 1-in. rivets. Where the lugs rest on the wall, 15-inch by 24-inch bearing plates, ⅝ inch thick, were provided, and between these and the lugs twelve ¾-inch steel rollers are placed to permit expansion and contraction. The shells are of ½ inch, and the heads of ⅝-inch flange steel, the dome shells and dome head being of 9-16 inch metal. The horizontal seams are triple riveted, with double butt straps. The seams joining the domes to the shells and the vertical seams of the domes are double riveted and staggered; all other seams are single riveted, the rivets being 15-16 inch in diameter, except in the supporting lugs.

FIG. 3.—AUXILIARY APPARATUS IN ENGINE ROOM.

The boilers are supported and enclosed in a setting of hard burned brick laid in cement mortor with headers every third course, and a brick arch is built about 2 inches above the shell and concentric therewith. The back connection, and the entire setting, where exposed to the flames and products of combustion, are lined with firebrick in fireclay batter. These bricks are bonded into the walls at every third course. Four pairs of extra heavy cast-iron buck-stays are placed on each setting with ¾-inch tie-rods extending across the top of the setting and connecting one buck-stay to its fellow directly opposite, while anchor bolts are used at the bottom of the stays. There are also ¾-inch tie-rods extending from the rear through the entire setting and bolting to the boiler fronts. Each boiler is provided with a sectional front made of ⅜-inch steel plates well bolted together with tee-bars placed on the back. The boilers are set in batteries of two each, and iron ladders are provided to reach the top of the setting for free access to the valves. Each boiler is provided with two 5-inch pop safety valves, set to blow at 90 pounds, and the usual steam gauge, water gauge, etc., that go with a first-class equipment. The grates are of the Swift improved rocking and dumping type, six sections to a boiler, each grate being 6 feet 6 inches by 7 feet.

The smoke and gases pass from each boiler through a wrought-iron breeching into a smoke flue common to each battery, the two smoke flues being connected with the smokestack by an oval smoke connection 54 inches by 66 inches. The stack is 60 inches in diameter inside and 125 feet high. It is of ⅜-inch wrought-iron plates, with lapped joints, and is unlined. The base is well anchored to the foundation with six anchor bolts 1⅜ inches in diameter. The stack is provided with gas-tight clean-out doors placed at a convenient height above the floor level. Each smoke flue is equipped with a positive damper operated by hand from the boiler-room floor, while in the main smoke connection, near the stack, a

swinging damper is located, which is operated by a Kieley automatic damper regulator.

The high-pressure piping consists of steam mains from the boilers to the main engines, the auxiliary header and branches supplying the pumps, and the live steam connection to the heating system. This also includes the high-pressure drip system from the steam mains, and the feed mains from the boiler feed pumps to the boilers, also the blow-off piping to the plug cock.

The low-pressure piping includes the exhaust pipes from the main engines and auxiliaries, the feed and water supply pipes and low-pressure drip piping, and the blow-off piping beyond the plug cock.

Enclosed in the steam dome of each boiler is a 7-inch Potter mesh separator and superheater, to which is joined a 7-inch branch leading to the steam main. These branches have bends in horizontal and vertical planes that provide against strains due to expansion and contraction. Two valves are placed in each branch, one at the separator and the other at the tee in the steam main. The steam main increases from 7 inches in diameter where the first branch connects with it to 12 inches in diameter beyond the last branch. This header passes through the division wall about 12 feet above the floor, after which it descends and delivers to a 12-inch transverse header level with the engine-room floor. The connections to the main engines are taken from the top of this header and are carried over the engines, ending in a De Reyke separator which is connected to the throttle valve. A valve is placed on each of these connections where they leave the header.

The steam for the pumps is taken from the header just mentioned through a 7-inch pipe which forms an auxiliary header, from which all connections to the pumps are taken. From the transverse header is also taken a branch for the purpose of supplying live steam to the heating systems of the central portion and the east wing. There is also a 7-inch connection made through a De Reyke separator to the heating system of the west wing. The high-pressure steam piping throughout is well equipped with valves for the protection and cutting out of any disabled portion of the plant. All high-pressure mains, branch connections, separators, etc., are dripped through Nason traps, which discharge into a high-pressure drip tank. The drip pipes from the mains and from each piece of apparatus are trapped separately and each trap has a bypass. The high-pressure drip tank is 3 feet in diameter by 5 feet long, and is fitted with a manhole in the head, and gauge glass, vapor pipe, etc. This tank is emptied by a pump controlled by a Kieley automatic pump governor discharging into the boiler feed line.

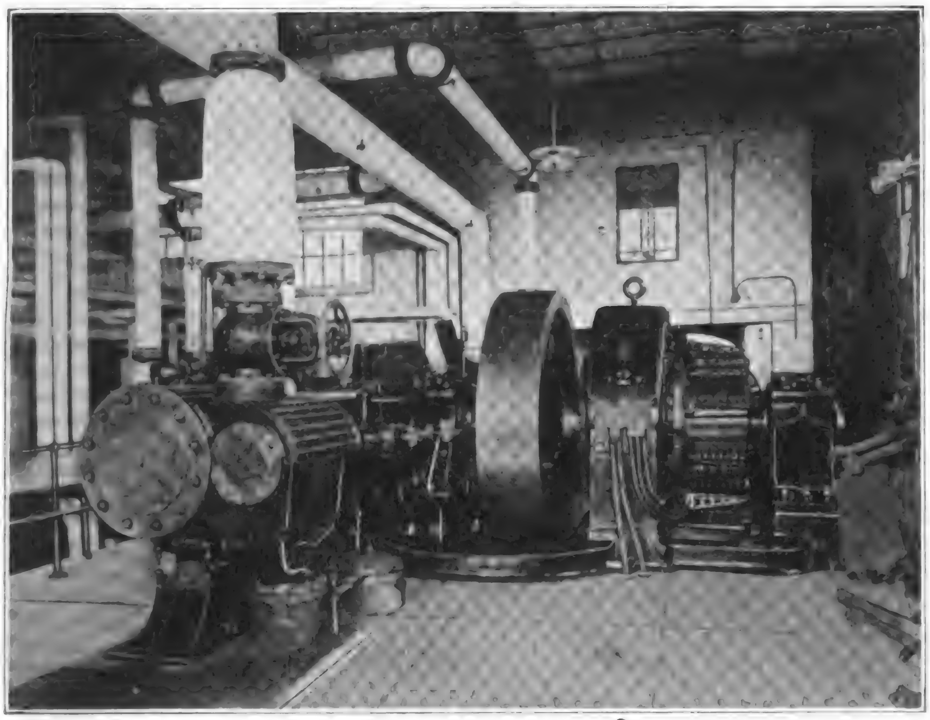

FIG. 4.—VIEW OF ONE OF THE 200-KW UNITS.

The boiler feed-water system consists of a 3-inch supply from the city mains to a 7½ by 5 by 6-inch duplex pump, from which it is discharged into a 3-inch main. The discharge from this high-pressure drip pump is also connected to the main, which connects to a Ward feed-water filter and a Berryman feed-water heater, which is located in the main exhaust system and used as an induction or dead-end heater. The feed line is so arranged that either the filter or the heater, or both, may be by-passed. From the heater the line passes directly over the boiler fronts from which 2-inch branches are taken to feed into Fox water arches which are connected to the boilers. In each branch an angle valve is placed next to the header with a check and straightaway gate valve near the floor between this and the water arch. As an extra precaution, two monitor injectors have been installed in the feed system. These are piped so as to send the water through the filter and heater before it reaches the boiler.

The Ward filter is composed of six cast-iron cylinders, 12 inches in diameter by 7 feet high over all, which are fitted with a complete set of special cast-zinc bars and filled with animal charcoal. It is provided with a removable outside strainer box and has a 3-inch feed-water inlet and outlet. It is built for a working pressure of 150 pounds. The heater used is an induction or dead-end heater which has no exhaust outlet, the action being as follows: Steam from the exhaust enters the heater, filling the steam space around the tubes, and the cold water passing through the tubes condenses some of the steam, thus lowering the pressure in the heater. The continuous flow of cold water through the tubes and the consequent condensing of the exhaust induces a constant flow of steam into the heater, hence the name induction heater. Each pound of steam entering the heater brings with it a certain amount of entrained air. This passes out from the top through a small vapor pipe, which sometimes discharges into the exhaust main, but in this case discharges into the vapor pipe leading to the roof.

The main exhaust header is located directly under the main steam header and begins at the north end of the pump room, running south and ending in a muffler tank. It increases from 8 inches in diameter, where the exhaust from the first engine enters to 10 inches in diameter, where it enters the muffler tank. The exhaust branches from the main engine enter the header at the bottom after passing under the floor in trenches, which are covered with cast-iron floor plates. From the outlet of the muffler tank, the exhaust pipe rises vertically to a 10 by 10 by 10-inch tee, from one outlet of which a 10-inch pipe runs to the heater main. Between this heater main and tee is located the connection to the induction heater. Just beyond the 10 by 10 by 10-inch tee is placed a Kieley back-pressure valve from which a free exhaust, 10 inches in diameter, is carried to the top of the smokestack, ending in a copper exhaust head. The exhaust steam from all the pumps is delivered to this exhaust main through an auxiliary header 7 inches in diameter. Gate valves are used throughout on the main exhaust headers, and on all branches to main engines and pumps. A complete system of low-pressure drips is used, connecting with the exhaust main and branches wherever required from the cylinders of all engines and pumps, the exhaust head, the muffler tank, feed-water heater, etc. This system empties into a low-pressure drip tank. The drips from the exhaust pipe and from each engine pump, etc., are trapped separately.

At the rear of the boilers, directly on the floor, is the blow-off main 3 inches in diameter, which ends in a blow-off tank. Each boiler is connected through a 3-inch branch, which has a 3-inch blow-off plug cock. The blow-off tank is 3 feet in diameter by 8 feet high. It is fitted with a manhole, glass water gauge, etc., and contains a cooling

coil of seamless brass pipe, 3 inches in diameter containing 60 linear feet. The outlet is connected to the blow-off pump, which discharges to the sewer. The sewer being above the level of the blow-off tank, made it necessary to have a pump for this purpose. The boiler blow-off from the boiler shell to the plug cock just outside the setting is of 3-inch extra heavy wrought-iron pipe encased in firebrick.

Vapor pipes 2½ inches in diameter are provided from the blow-off and drip tanks with a valve placed on each. These are connected to a 4-inch main vapor pipe leading to the top of the smokestack and ending in a copper exhaust head.

The pipe used for the high-pressure mains is of standard full-weight wrought iron with extra heavy flange fittings. Pipes above 4 inches have flanged joints packed with copper corrugated gaskets, while those less than 4 inches in diameter have screw joints without any packing. The boiler feed pipes are of iron size hard-drawn brass, with brass fittings. All cold-water pipes are of standard guaranteed full weight galvanized wrought iron with galvanized fittings. Particular care was exercised in installing the live steam exhaust pipes, with a view to preventing noise and vibration.

The valves used on the high-pressure steam pipes are gate valves of extra heavy pattern with ribbed or recessed flanges, bronze discs and seats, and composition spindles and stuffing boxes. The valves on the feed line are of extra heavy brass. All other valves, 2 inches in diameter or less, are of steam metal, with finished trimmings; those over 2 inches have iron bodies and brass trimmings. All valves, except the angle valves used where the feed branch to the water arch leaves the feed main and the plug cocks in the blow-off pipes, are of the gate type.

Magnesia pipe covering is used throughout. The pipes passing through the tunnels and in trenches underneath the engine room floor, have an extra covering of No. 10 canvas drawn tight and neatly sewed and then painted with two coats of fire-proof paint. The domes of the boilers, the feed-water heater, the feed-water filter, all tanks, separators, pump governors, traps, fittings, valves, etc., are covered with magnesia blocks 1½ inches thick, securely wired, the whole neatly covered with a No. 10 canvas jacket and painted with two coats of fire-proof paint.

The smoke connections and the stack up to the roof are covered with magnesia blocks 1½ inches thick, and finished with hard plaster. The covering is placed on a framework of wire net surrounding the smoke connections and stack 2 inches from the iron, thus forming an air space. This covering is painted with black Japan varnish.

The pumps located in the pump room are as follows: Two 7½ by 5 by 6-inch pumps for returning the water of condensation from the receiving tank and for feeding fresh water into boilers; three 6 by 4 by 6-inch pumps for draining the high-pressure and low-pressure drip tanks and the blow-off tank; one 10 by 6 by 10-inch pump for house service, and one 14 by 7 by 10-inch Underwriters' fire pump. These pumps are all of the duplex type, built for a working pressure of 150 pounds. The house service and fire pumps are provided with Ford regulators and safety draining devices.

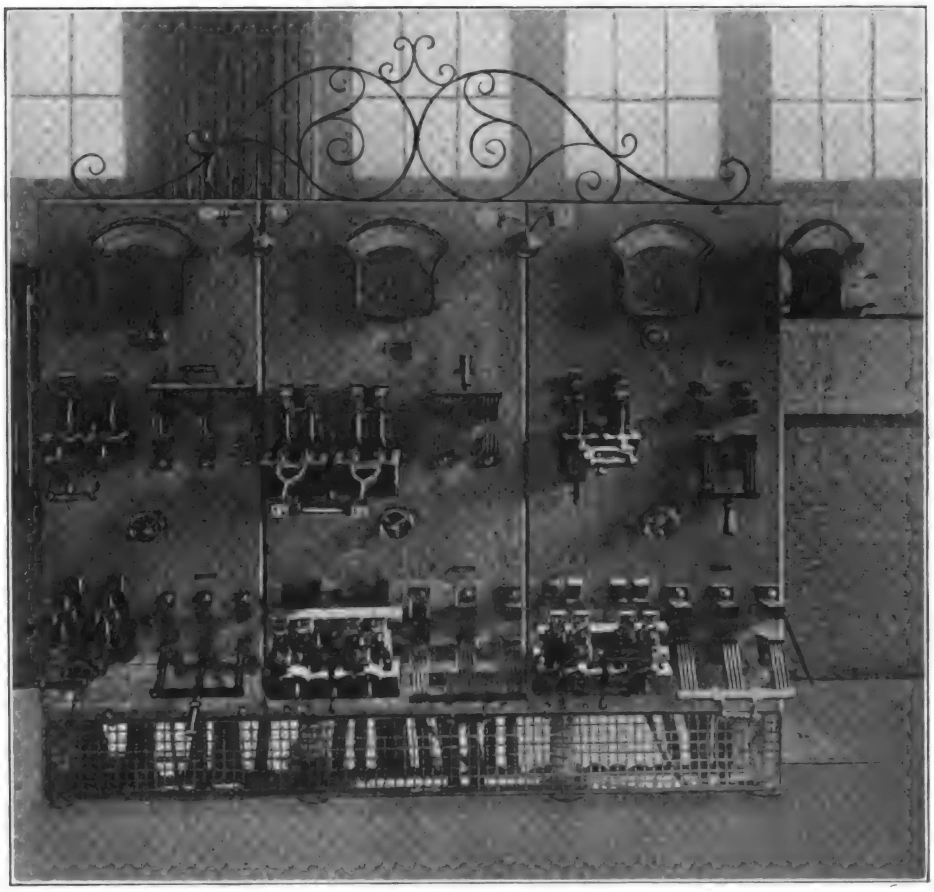

FIG. 5.—MAIN SWITCHBOARD IN ENGINE ROOM.

Three engines of the Harrisburg standard high-pressure type built by the Harrisburg Foundry and Machine Works, of Harrisburg, Pa., furnish the motive power. Two of these have a capacity of 320 horse-power each, and the other has a capacity of 120 horse-power. Following are the principal dimensions of the engines:

	Large engines.	Small engine.
Diameter of cylinder	22 ins.	15 ins.
Length of stroke	20 ins.	14 ins.
Revolutions per minute	200	275
Guaranteed horse-power	320	120
Diameter of steam pipes ...	7 ins.	5 ins.
Diameter of exhaust pipe ..	9 ins.	6 ins.
Type of governor	Fly-wheel governor	
Initial steam pressure	80 pounds	
Point of cut-off	25 per cent	

These engines are of the direct-connected type, the sub-base under each engine supporting the generator and out-board bearing. Each engine is equipped with a Manzel oil pump for lubricating the cylinders.

The dynamos are Keystone multipolar direct-current compound-wound machines, built by the Burke Electric Company, of Erie, Pa., the principal data being as follows:

	Kw.	Speed.	Volt.	Amp.
Large dynamos	200	200 r.p.m.	125	1600
Small dynamo	75	270 r.p.m.	125	600

They are guaranteed to operate under full normal load for twenty-four hours per day without any undue heating.

A rather peculiar arrangement of switchboards has been adopted. The main switchboard in the dynamo room feeds the switchboard used in connection with the old plant. In the central portion another switchboard is located for controlling the lights used there and for lights in the east wing. Still another switchboard, from which the stage lights are manipulated, is located in the auditorium. The main switchboard is made up of three panels of gray Tennessee marble. All exposed work on the face of the board is highly finished in bright copper. The usual instruments, switches and circuit-breakers are provided. The board in the west wing is fed by feeders from the main switchboard, which connect with the bus-bars already in place. The lights used in this wing and the passenger elevator are controlled from this board.

The switchboard in the central portion is equipped with nineteen auxiliary circuit-breakers, nineteen knife switches, one main circuit-breaker, and one main knife switch of 1500 amperes capacity. The other knife switches and circuit-breakers vary in size, depending upon the load they carry. The board is of Tennessee marble trimmed with a nickle frame.

At the rear of the stage in the auditorium is a small switchboard from which the light effect on the stage is controlled. This board has four dimmers mounted upon it, together with numerous switches and fuse blocks.

There are furnished in position the following feeders: One set of cables leading from the main switchboard to the switchboard in the west wing. One set of cables leading from the main switchboard to the switchboard in the central portion of the

building. A set of empty conduits lead from the main switchboard into the central façade, which are to be ultimatley used to hold cables conveying current to this switchboard for the east wing. One set of cables connects each dynamo to the main switchboard. The compensating leads are of the same size as the positive and negative leads. All of the cables are flexible stranded, composed of No. 16 B. & S. conductors having an insulation of rubber and covered with lead armor heavily tinned. The generator leads, however, are not lead armored, but have two layers of tape put on spirally in opposite directions, and are then covered with two substantial braidings well coated with preservative.

For the information and data incorporated in the above, the writer is indebted to Mr. Lewis J. Hart, engineer in charge of the plant.

THE CHEMICAL PURIFICATION OF BOILER FEED-WATER.

BY GEORGE E. WALSH.

The economy secured by the purification of boiler feed-water varies according to the chemical constituents of the water. Very few plants obtain water entirely free from boiler-incrusting constituents. Some mountain streams are quite pure. while others contain so much limestone, gypsum, free sulphuric acid, and magnesium chloride that the efficiency of a boiler is very greatly reduced. Water flowing through peat bogs often contains corrosive acids in such quantity that the life of the boiler is quickly affected, while in the great coal districts feed-water is apt to be heavily impregnated by iron salts and free sulphuric acid.

It has been estimated that a scale of sulphate of lime one-sixteenth of an inch thick will reduce the efficiency of a boiler 14.7 per cent. As there is a difference in the conducting power of boiler scale composed of different chemical compounds, the loss in boiler heating of water varies considerably. In experiments made with boilers coated inside with plaster of Paris and with Portland cement, it was found that it required no more time to heat the water in the boiler coated with plaster of Paris than in a clean one, but in the cement-lined boiler it took 19 to 23 minutes to heat the water to 205 degs. Fahrenheit, while 16 minutes were required in the clean boiler.

The conductivity of the boiler scale is therefore an important consideration. The loss depends upon the kind of scale and not altogether upon its thickness. The relative value of chemical water purifiers is therefore a matter depending on the analysis of the feed-water. Very few boiler-scales are as harmless as plaster of Paris or Portland cement.

The practice of purifying the feed-water is quite general now in large plants throughout the country. Both mechanical and chemical treatment has been carried to a relatively high point of success, and the results obtained indicate a great saving. The purifying and softening of the feed-water is doing away with the mechanical washing and cleaning of the boilers, except at long intervals, and there is a direct saving in boiler repairs and labor of washing that averages from 50 to 75 per cent. Frequent blowing-off for the removal of sludge and scale is also costly in the end.

Of the many chemicals used for purifying feed-water, sodium phosphate is best, and soda ash and lime next. When applied direct in the boiler the soda ash causes the incrusting solids to change to carbonates. When precipitated in the boiler in this form, they can easily be blown off as soft sludge. In their former condition the solids when precipitated in the boiler adhere to the sides and are not easily dislodged except by some mechanical cleaning method. This chemical treatment is inexpensive at the beginning, but it requires frequent blowing-off to remove all particles. In small plants where it is not advisable to build expensive softening plants, it produces good results. This practice must be kept up continually to keep down the boiler-scale, and where very hard water is used sufficient soda must be introduced to cause foaming of the water when blown-off.

The amount of soda ash used to each thousand gallons of water should be 0.16 per pound of magnesium chloride, 0.13 of magnesium sulphate, 0.10 of calcium sulphate, 0.02 of magnesium carbonate, and 0.02 of calcium carbonate.

The phosphate of soda, or tri-sodium phosphate, has been employed very extensively for purifying feed-water for boilers, but it costs three or four times as much as the soda ash. On the other hand, it is more effective in its results, for in precipitating the lime salts it makes them absolutely non-adherent. They are easily blown off, and practically none adhere permanently to the sides of the boiler. To make the effect as great as possible the water should be slightly heated, for the chemical action is very slow without heat. No expensive plant is required for purifying the water with tri-sodium phosphate. A gauged barrel is generally attached to the feed line, and the direct application of the chemicals to the water is automatically obtained.

In all the different treatments of impure feed-water for boilers, the question of the constituents of the water should determine the character of the chemical formula. Manufacturers drawing their boiler feed-water from streams in coal-mining sections have obtained excellent results by means of milk of lime. Lime and soda ash in equivalent amounts have given the best results, however, for in the milk of lime treatment sulphate of lime is left in the boiler, and this of itself is a scale-forming substance.

The treatment of feed-water by chemicals introduced directly into the boiler or pipes is a cheap method for preventing the formation of scale in boilers, but it is unsatsfactory in the end for large plants unless softening machines are employed. The water-softening and purifying plant costs considerable at the outset. But where the boiler feed-water is laden with acids that tend to form boiler scale, it is poor economy to resort to temporary makeshifts.

There are several types of water-softening machines in use, but all of them seek to produce chemical action by means of heat before the mixture enters the feed-water. There are both intermittent and continuous softening plants. In the former the water enters the storage tanks at certain intervals where it is softened and purified chemically. In the latter system the feed is continuous, and the softening and purification goes on without cessation. The flow of the water to the plant operates all the mechanism used, and regulates the action so that no operator is needed to watch it. The chemicals are likewise fed automatically so that perfect uniformity of feed-water can be depended upon. The chemicals are mixed with hot water in the continuous system, and when they enter the feed-water they immediately act upon it. The chemical reaction proceeds automatically until the water is thoroughly softened and the mechanical action of sedimentation is made perfect. A filter finally completes the process.

The cost of softening plants is not so great as the difference in the loss of effective and non-effective boilers proves in the end. The cost for small plants is proportionately larger than for those from 5000 to 20,000 horse-power. Where steel tanks are used, the softening plants cost from $4 to $5 per horse-power for installations. These prices apply to plants below 1000 horse-power. Above this and up to 2000 horse-power, the price of installation runs down from $4 to $3, while from 2000 to 5000-h.p. plants the cost may run as low as $3 and $2. With very large plants the saving is quite remarkable. Although few companies quote prices lower than $2 and $3 per horse-power for large plants, a number have installed 15,000 and 20,000-h.p. plants at a cost as low as $1.20 per horse-power of installation. For such establishments the economy obtained is out of all proportion to the loss that would follow the disuse of softening machines.

The depreciation of softening plants is an item worth considering. Wooden tanks depreciate very rapidly, and unless their cost of construction is much lower than steel they are not good investments. Where reasonable care is exercised steel tanks do not, as a rule, show more than 5 per cent. depreciation a year.

The further cost other than the construction and maintenance of softening plants comes from the chemicals used. Lime and soda ash are fortunately cheap, and so is tri-sodium phosphate, which sells from 4 to 5 cents a pound. A good deal of the commercial lime, however, contains a high percentage of magnesia, and unless a brand containing from 90 to 95 per cent. of lime can be obtained it should be rejected for water-softening purposes. Water which

owes its hardness chiefly to carbonates of lime and magnesia is very easily and cheaply ~~softened~~. ~~Water containing~~ sulphates and other soluble compounds of lime and magnesia is more expensive to purify. The cost of softening waters varies from 1 to 2 cents per 1000 gallons, for while it takes only 2 mills per 1000 gallons to remove 1.42 pounds of carbonate of lime by the lime-water treatment, it requires 1 cent and 2 mills per 1000 gallons to remove ten grains of sulphate of lime, and more in proportion to remove sulphate of magnesia.

The economy effected consists of saving boilers for longer periods of work, and substantial economy in fuel and repairs. It is impossible to secure satisfactory, continuous service from boilers coated with only a thin scale. If plants are not supplied with water-softening machines, the direct application of chemicals to the feed-water will greatly lessen the loss and waste. Scale may ultimately form inside of boilers thus treated, unless watched carefully and the precipitated sediment blown off systematically. But the saving is considerable even where this practice is resorted to.

A saving of 15 to 16 per cent. in the efficiency of a boiler is a factor in the operation of a steam plant that amounts to a large total at the end of a year. But if one adds to this a saving of 15 per cent. in the fuel another stage in the question of economy is reached that appeals more directly to the cost of operation. A number of tests carefully computed show that the average saving in fuel runs from 10 to 16 per cent. Even in using Lake Michigan water, which contains 12.16 parts of scale-forming substances, a saving in coal amounting to 25 to 35 cents per ton has been effected by the use of water-softening plants.

Only an approximate estimate of the actual saving effected in purifying and softening feed-water before it enters the boiler can at best be obtained, but sufficient tests and practical data are available to show that it is a vital question in modern steam-operated plants. The fact that some reports indicate the loss with ordinary feed-water is inconsiderable shows that the quality of the water used is unusually good. The loss of one plant, however, need not, necessarily be that of another. Feed-water must be taken into account in estimating the cost of operating a plant in any given part of the country. An analysis of the water should be made before the first stone of the foundation has been laid. Otherwise, the question of cost of operation may materially differ from the first figures given.

Sulphate of lime deposits its scale in the boiler so gradually that the danger is often misunderstood. But the scale increases in concentration and hardening until the coating becomes a permanent barrier against free heat conductivity. Many other scale-forming substances are deposited much faster than sulphate of lime, and they are correspondingly easier to remove. Some feed-water heaters will partly neutralize these deposits, and they are sometimes removed in considerable quantity by scum-catchers or blow-off cocks. But all the carbonate of lime cannot be removed in this way.

PREDETERMINATION OF SOLENOID CHARACTERISTICS.

BY PAUL C. PERCY.

In order to work a solenoid to best advantage, it should be proportioned so that when the plunger is all the way in, the magnetic density in it is extremely high. The writer has been accustomed to make the magnetic circuit such that when the plunger is "home," the calculated density in it is about 120,000 lines per square inch and in the yoke or exterior portion of the circuit about 60,000 lines per square inch. The "neck" of the solenoid, or that part through which the plunger slides, should be long enough to make the magnetic reluctance of the annular air-gap there very low as compared with the main air-gap when the plunger is in its idle position; a good proportion for ordinary work is obtained by making the annular air-gap ten times the area of the plunger cross-section. This is accomplished with sufficient closeness by making the length of the neck 2½ times the diameter of the plunger.

It is necessary to interpose a non-magnetic buffer between the inner end of the plunger and that part of the magnetic

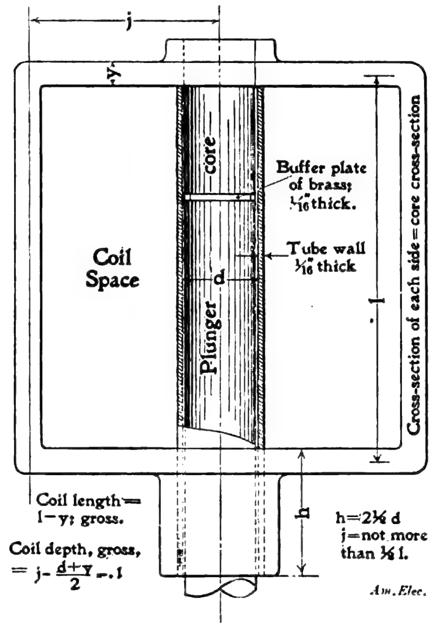

FIG. 1.—STOPPED SOLENOID.

circuit against which it would otherwise be drawn when the solenoid is excited; if this is not done, the plunger will not release promptly when the coil is disconnected from the supply source. A brass plate or screw-head 1-16 inch thick will answer this requirement. The plunger must also be prevented from making magnetic contact with the neck of the frame; a brass bushing with a 1-16-in. wall will serve here. This makes two air-gaps each 1-16 inch long when the plunger is "home," the cross-sectional areas of which have a ratio of 1 to 10 if the plunger is flat-ended.

Coning the end of the plunger and recessing the stationary part of the frame to match it have the effect of making the pull more nearly uniform throughout the travel of the plunger, but as this complicates the calculation of the air-gap and does not increase the initial pull, all other factors being the same, the writer prefers a plain, flat-ended plunger, co-operating with a stationary flat-ended core of the same diameter inside the coil. This article, therefore, is based on a "stopped" solenoid of this type, as shown by Fig. 1.

It will be found that in practice the length of the magnetic path in the yoke need never exceed twice the length of path in the core and plunger when the latter is against the buffer; if it should exceed this proportion, the plunger travel will usually be so small in comparison to its diameter that an ordinary electromagnet could be used to advantage.

Good machinery steel, such as plungers and cores are usually made of, requires about 470 ampere-turns per inch of length for magnetization at 120,000 lines per sq-in.; cast steel yokes at 60,000 lines density require about 15 ampere-turns per inch of magnetic path length. The air-gap between the ends of the plunger and core will require 2350 ampere-turns when the plunger is "home," and the annular air-gap will require 235 ampere-turns under the same condition. Therefore, the total excitation required to produce a magnetic density of 120,000 lines per square inch in the plunger when it is against the buffer plate or screw will be $2585 + 500\,l$; l being the active length of the core and plunger as indicated in the diagram, and the path length in the yoke being taken as twice the value of l. To cover the looseness of the plunger in the brass bushing at the neck the ampere-turns for the two air-gaps may be reasonably made 2600 instead of 2585; then we have the relation:

$$\text{Ampere-turns} = 500\,l + 2600 \quad . \; . \; . \; . \quad (a)$$

Table I is calculated on this basis and will serve for most practical cases.

TABLE I.

Ampere-turns for Different Core + Plunger Lengths.

Core + plunger length.	Ampere-turns.	Core + plunger length.	Ampere-turns.	Core + plunger length.	Ampere-turns.

The next step is to determine the approximate pull of the solenoid, or to pro-

portion it to give a predetermined pull. In considering this part of the problem, the writer has based all calculations on the fundamental formula for the tractive force of a magnet when the armature is in contact with the polefaces. This, of course, is inaccurate for a solenoid when there is an appreciable air-gap between the ends of the stationary core and the plunger, but it gives results in favor of the solenoid—that is, the actual pull is greater than the calculated pull—in most cases.

At any given magnetic density in the core, plunger and main air-gap, the ampere-turns required to force the flux through the different parts of the magnetic circuit are readily ascertained; deducting the ampere-turns required by the core, plunger, yoke and neck air-gap from the constant ampere-turns in the coil, which is always equal to 500 l + 2600, leaves the ampere-turns available for the main air-gap. Dividing these by the ampere-turns per inch required at the given density obviously gives the length of main air-gap at which the assumed density will be obtained. Table II has been computed in this way, and will usually give results better than those desired, provided the steel used in the frame and plunger is of good magnetic quality.

The table is instructive in several particulars aside from its value in determining actual dimensions. It shows, for example, that in order to work at high magnetic densities in the core and main air-gap, the magnetizing coil must be enormously long in comparison with the plunger travel; thus, if one wished to lift 100 pounds through a travel of ¾ inch with a core not over 2 inches in diameter, the density would need to be about 50,000 lines per square inch of cross-section, and the length of coil necessary for ¾ inch travel might be 21½ inches.

TABLE II.
Relation Between Plunger Travel, Maximum Coil Length, Density in Core, and Pull.

The numbers in the body of the table are maximum allowable lengths of the magnetizing coil.
The numbers at the heads of columns are magnetic densities in the core, in kilo-lines per square inch.

Pull co-efficient=	39.2	32.9	27.2	22.0	17.4	13.3	8.8	6.8	4.3	3.5	1.1	0.53	

Note: The pull in pounds is approximately equal to $D^2 \times$co-efficient. The core diameter, D, required is approximately equal to $\sqrt{\text{pull} \div \text{co-efficient}}$.

A couple of examples taken from practice will serve to illustrate the application of the tables and the method on which they are based. Suppose one wishes to build a solenoid to lift 75 lbs. 1¼ inches. To use Table II, the density must be 40,000 or less because no coil lengths are given for densities above 40,000. It will always save time and trouble to tabulate trial values. In the present case the following preliminary tabulation would be made:

Core density.	Core diameter.	Coil length.	Ampere-turns.
20,000	4.18	11 5/8	8162
25,000	3.32	15 7/8	10540
30,000	2.92	20 1/8	12663
35,000	2.375	24 1/4	14725

From this it becomes evident that either 25,000 or 30,000 lines density is preferable to the others; the writer's preference would be for a 3-inch core and a trifle under 30,000 lines per square inch. A solenoid built for this duty had a 3-inch core, a coil 18 inches long and an excitation of 12,400 ampere-turns.

As the second example, suppose 30 lbs. must be lifted 1 inch. The following preliminary tabulation will be made:

Core density.	Core diameter.	Coil length.	Ampere-turns.
15,000	3.46	5	.5100
20,000	2.65	8 3/8	6788
25,000	2.1	11 7/8	8538
30,000	1.85	15 3/8	10288

In this case the writer adopted a 2-inch core with a coil 12 inches long. The excitation required by test was 8400 ampere-turns.

It should be remembered that the method herein described is not intended to give absolutely accurate results, nor to enable one to determine dimensions and excitation within 1 per cent. or 2 per cent. It is useful in getting at approximate dimensions and excitation, however, and after a little experience in its use, one readily develops sufficient judgment to design a stopped solenoid which requires no alteration in the frame and core. The exciting coil may be laid out by means of the article by the editor of this journal which appeared in the January, 1904, number.

STEAM PIPES.

BY R. T. STROHM.

A system of steam piping which is correctly designed and properly installed adds greatly to the continuous working capacity of a plant, since it insures comparative freedom from annoying accidents and occasional shutdowns which are all too frequent in plants badly designed or improperly erected. For the steam piping is to the plant what the system of blood-vessels is to the body. A defect in either must inevitably cause trouble.

The steam piping in a power plant may be divided into a number of classes. There is the main steam pipe, connecting the boilers and the engines; the piping which supplies steam to the boiler feed pumps and other auxiliary apparatus; the exhaust piping from the engines; and the steam heating system. In this article, however, only the main steam pipes to and from the engines are considered.

Steam mains are made sometimes of cast-iron for very low pressures, but for ordinary power plant boiler pressures they are usually of wrought-iron pipe, either lap or butt-welded. Steel is also used as

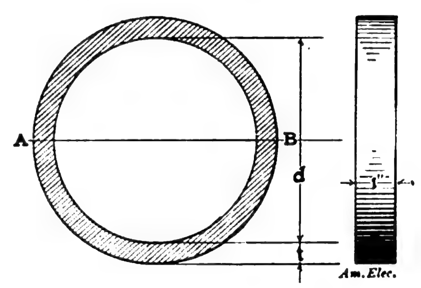

FIG. 1.

piping material, and it has steadily grown in favor during recent years for pipes subjected to the action of high-pressure and superheated steam.

The main steam pipe is such an important part of the steam plant equipment, and its failure is fraught with so many possibilities of disastrous consequences, that too much care cannot be exercised in the selection of the material and in its erection. A cylindrical pipe subjected to internal pressure is in the same condition as a cylindrical boiler under pressure. The stress on a section of pipe one inch long, tending to tear it into two parts, is equal to the steam pressure (p) in pounds per square inch multiplied by the diameter (d) of the pipe in inches. If t equals the thickness of the pipe in inches, the cross-section per inch of pipe length at each end of the diameter AB, Fig. 1, is $t \times 1 = t$ square inches. As the stress $p \times d$ is resisted by the metal at A and B, it is evident that $\frac{p\,d}{2}$ is the stress on each section. Denoting the

safe fiber stress by f, the formula for the thickness of a pipe becomes $t = \frac{pd}{2f}$. For cast-iron pipe, the value of f should not be greater than 1800 pounds per square inch. Of course, for pipes of small diameter, this rule will give the thicknesses too small to be cast easily or successfully, so that the actual thickness will need to be greater than the calculated thickness.

In the case of lap-welded wrought-iron pipes, the value of f should be about 3000, which gives a factor of safety of about 15. Considering that a steam pipe is subjected not only to stresses due to steam pressure, but also to others caused by the change in temperature, this factor is not excessive. Mild steel, such as is used for steam pipes has a tensile strength of about 50,000 pounds per square inch. If this value is much increased, the steel becomes too brittle for satisfactory working. Taking a factor of safety of 15, the safe fiber stress (f) to be used in the case of steel pipes becomes approximately 3500 pounds.

Pipes made of mild steel may be either drawn or welded. In the comparatively small sizes, they are easily solid-drawn, but above 8 or 10 inches diameter welding is resorted to. A solid-drawn pipe, when properly finished, presents smooth internal and external surfaces, and is free from scale or grooves. These pipes should always be annealed after being drawn, to reduce the internal stresses set up during the drawing and cooling processes. In the case of cast-iron pipes, the cooling stresses cannot easily be avoided, and on this account the factor of safety for that material approaches 20.

Welded steel pipes are made by bending the plates and making a longitudinal lap weld. This, if properly done, should give a strong and safe construction. In some instances, however, the security of the welded joint was doubted, and accordingly a narrow strap was riveted to the pipe, longitudinally, covering the entire weld, in order to strengthen the joint.

A main steam pipe should be proportioned so as to deliver the required amount of steam at the given pressure, with a minimum loss of pressure in the transmission. Steam, in flowing through a pipe, suffers a loss in pressure due to the resistance of the pipe walls, bends and fittings, as well as to a certain amount of radiation which cannot be prevented. Experience has taught that the steam in a pipe leading from the boiler to the engine should travel at not more than 6000 feet per minute. Hence, to find the size of steam pipe required to supply a given engine, one may use the formula

$$d = D\sqrt{\frac{S \times r.p.m.}{36{,}000}} \qquad \text{(1)}$$

in which

d = internal diameter of steam pipe, in inches.

D = diameter of engine cylinder bore in inches.

S = piston stroke of engine in inches.

$r.p.m.$ = revolutions per minute.

This rule assumes that steam follows the piston throughout the entire stroke. In reality, of course, the steam flows into the cylinder up to the point of cut-off, after which there is a cessation of flow until admission occurs at the other end of the cylinder. The flow of steam through the end of the pipe opening into the steam chest is therefore a series of pulsations, of greater or less frequency, depending upon the rotative speed of the engine. To insure sufficient capacity, however, the pipe is made large enough to supply the engine if it should take steam throughout the full stroke.

If the engine makes a very large number of revolutions per minute, trouble will be experienced by wire-drawing of the steam during admission. This causes a decided downward slope of the indicator card steam line, instead of the usual horizontal line so familiar in the indicator diagrams of slow-running engines. To avoid, or at least to mitigate this evil, a receiver may be placed near the engine. This receiver, having a volume greater than that of the cylinder, acts as a reservoir, with the result that a more uniform pressure is obtained during the admission period.

Nevertheless, the initial pressure in the cylinder will be less than the boiler pressure because of the resistance to the flow of steam offered by the pipe and its various connections. The drop in pressure varies directly as the length of the pipe. But a large pipe will offer less resistance than a small pipe of equal length, other conditions being the same. It is frequently desired to know what loss of pressure may be expected from a steam pipe of given length and diameter, knowing the initial pressure and the amount to be discharged. For a problem of this nature, the following formula may be used:

$$p' = \frac{W^2 L k}{7{,}500{,}000{,}000\, w} \qquad \text{(2)}$$

in which

p' = loss of pressure in pounds per square inch.

W = discharge of steam, in pounds per minute.

L = equivalent length of pipe, in feet.

w = weight of a cubic foot of steam, at the given initial pressure, in pounds.

$$\text{and } k = \frac{1 + \frac{3.6}{d}}{d^5} \times 1{,}000{,}000.$$

The accompanying table gives values of k for standard pipe sizes. It will be observed that L is given as the *equivalent* length of pipe. By this is meant the length of straight pipe of the given diameter which will give the same friction as the pipe under consideration, with all its elbows and valves. It is evident that the change of direction in an elbow or in a globe valve will add considerably to the friction, and so it is necessary to consider each right-angled elbow as equivalent to a length of straight pipe 40 times its diameter, and a globe valve as equivalent to a length of straight pipe 60 times its diameter. Thus, if a given steam pipe 4 inches in diameter and 40 feet long contains three elbows and two globe valves, the equivalent length of 4-inch pipe is 120 feet, since the three elbows are equivalent to 480 inches, or 40 feet of straight pipe, and the two globe valves are equivalent to 480 inches, or 40 feet of straight pipe.

TABLE I.

Values of k in Formula (2).

Pipe diam. =	3	3½	4	4½	5	6	7	8	10	12
Value of k =	9050	3860	1855	975	551	205.8	90	44	13.6	5.225

Formula (2) may be used to calculate the diameter of a steam pipe, knowing the initial pressure, the allowable drop in pressure, the length of pipe, and the quantity to be discharged, or it may be used to determine the discharge of steam from a pipe, under certain known conditions. In finding the amount of steam discharged, however, there is one peculiarity to be remembered regarding the flow of steam. When the discharge pressure becomes as low as 58 per cent. of the initial pressure, the weight of steam discharged in a given time becomes a maximum. No further lowering of the discharge pressure will increase the flow, not even if the steam is caused to flow into a partial vacuum.

In exhaust steam mains it is not desirable to have the velocity of the steam exceed 4000 feet per minute. Consequently, for exhaust piping, formula (1) may be changed so as to read

$$d = D\sqrt{\frac{S \times r.p.m.}{24{,}000}} \qquad \text{(3)}$$

in which the letters used have the same significance as in formula (1).

It frequently happens that one main pipe must receive the combined discharge from a number of smaller branch pipes, or must convey sufficient steam to supply a number of branches successively. An instance of

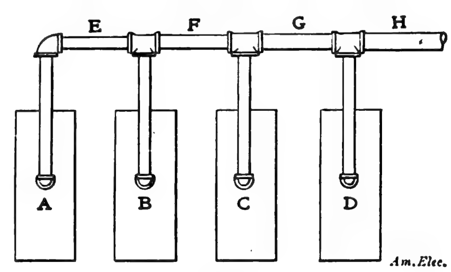

FIG. 2.

this is to be found in a steam main connecting a number of boilers as indicated in Fig. 2. It is obvious that the section of pipe, E, between the boilers A and B carries simply the steam generated in the boiler, A. But the section, F, must convey the discharge of both boilers, A and B. Hence, the area of the pipe, F, must be twice the area of the pipe, E. Similarly, the area of the pipe, G, must be three times that of E, and of H must be four times that of E. Thus the

pipe, *H*, must have a diameter twice as great as the diameter of the pipe, *E*; since the areas are proportional to the squares of the diameters. This arrangement of the main is not a desirable one.

The sections of pipe may be joined either by screwed or flanged joints. For the small sizes of wrought iron and steel pipe, the ordinary unions and couplings are used. In larger sizes, however, flanges are required. The manner in which the flanges are joined to the pipe is an important de-

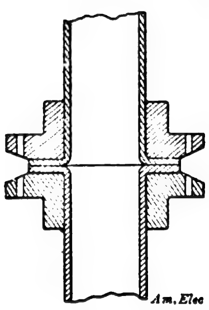

FIG. 3.

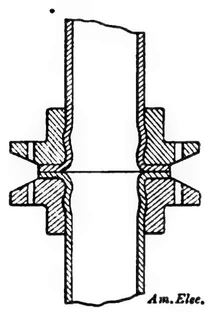

FIG. 4.

tail. The usual method of screwing the pipe into the flange has the disadvantage that it is liable to leak. Some manufacturers have sought to guard against this by making the threaded joint considerably longer, giving a greater number of threads in contact, and by thus having a longer hub lessening the liability of the flange being loosened by vibrations.

In fitting flanges to pipes the pipe should be screwed through the flange until it projects about 1-16 inch. After peening, the pipe should be put in a lathe and the projecting end cut off. Then a light cut should be taken across the entire face of the flange, which will insure its being at right angles to the pipe axis. Much of the trouble due to leaky flanged joints may be traced to neglect of this precaution, the flanges being therefore out of line at the time of erection. Flanges may be made of cast iron, wrought iron or steel.

Another method of obtaining a tight joint is illustrated in Figs. 3 and 4. The flange is slipped over the pipe and the pipe is then flanged over, as shown. In the method shown in Fig. 4, the additional precaution is taken of expanding the pipe into grooves in the flange. The riveting of cast-iron flanges to wrought-iron pipe is not to be commended, as any continued vibration is almost certain to loosen the joint and eventually cause leakage around the rivets.

PARALLEL OPERATION OF DYNAMOS HAVING DIFFERENT CHARACTERISTICS.

BY LAMAR LYNDON.

Generators are compounded for the purpose of maintaining a practically constant voltage at the end of the feeders. Theo-

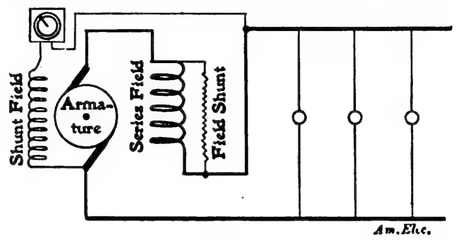

FIG. 1.

retically the compounding is adjusted so that the increase in dynamo voltage, produced by the magnetizing effect of the main current which flows through the series coils, is just equal to the increase in feeder drop due to increase of current flow. In this way the volts due to the compounding effect of the series windings are always equal to the volts of drop in the feeders. By the

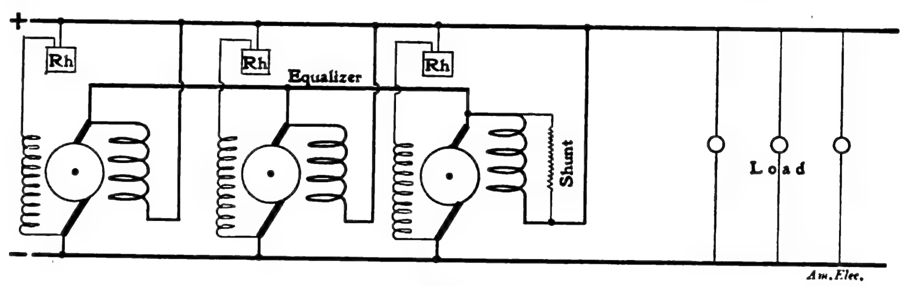

FIG. 2.

term "compounding effect" is meant the effect of increasing the voltage at full load above the voltage at no load; the compensation for internal losses in the generator—which requires some of the magnetization of the series winding—is not here taken into consideration.

The foregoing explanation, though seemingly unnecessary, is gone over to show that where a number of generators are run in parallel there is a certain number, only, of the machines in operation with which the increase of voltage due to compounding is equal to and neutralizes the feeder drop. If the number of machines in parallel differs

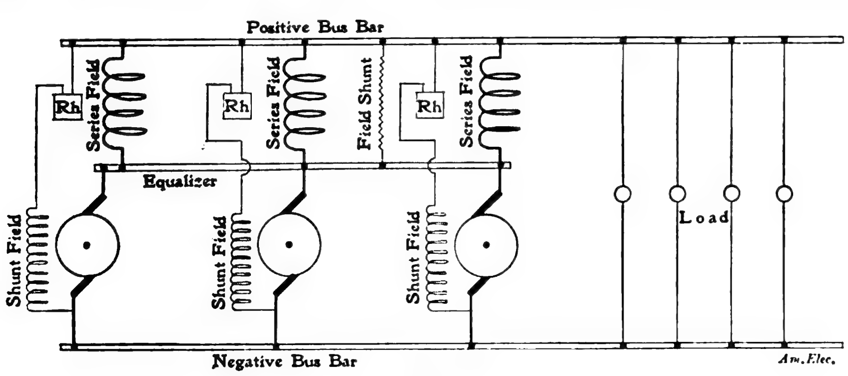

FIG. 3.

from this number, the desired equality between voltage increase and drop no longer exists.

Assume, for example, two generators, each of 1000 amperes capacity, giving 500 volts at no load and 550 volts at full load, and a system of feeders carrying 2000 amperes with 50 volts drop. When the load on the system is equal to the full capacity of both machines, the drop over the feeders is just equal to the increase in generator voltage. When, however, the load drops to 900 amperes and one machine is cut out, the compounded voltage of the working machine—assuming a straight line characteristic at this range—will be about $50 \times \frac{900}{1000} = 45$ volts. The drop in the line, however is only $50 \times \frac{900}{2000} = 22.5$ volts. That is, the compounding that is suitable for both generators is excessive for a single one, working on the same system of feeders, and to preserve constant pressure at the ends of the feeders, hand regulation must be employed. Obviously, on the other hand, if the compounding were of proper value for a single machine it would be too low for the full output of two machines.

Usually generators are built for about 10 per cent increase of voltage at full load above that at no load. The actual magnetization produced by the series turns may vary considerably with the character of the iron, the air gap and other constants of construction. Therefore, it is general practice to put on more turns than necessary, and by shunting part of the current out of the winding adjust the actual voltage rise to the desired value. Fig. 1 illustrates this method of adjustment.

Fig. 2 shows diagrammatically three machines in parallel, all of them having their series coils connected between the positive and equalizer bus-bars, and one of the machines having its series field winding shunted. By following the connections, it will be clear that the shunt strip is in effect also connected between the positive and the equalizer bus-bars, and therefore a shunt across the series coils of any machine is a shunt across all of them. This is indicated in Fig. 3, which is the equivalent electrically of Fig. 2. This explains why it is impossible to adjust compound-wound machines with series field shunts when several of them are connected in parallel.

In parallel running the series field windings are all connected in parallel, and may be considered as being supplied from a source of current having a low e.m.f. varying directly as the load varies. Referring to Fig. 3, it will be clear that the drop through any series winding must be the same as that of each of the others for any given load, regardless of the size or capacity of the ma-

chines which are working together, since they are all connected across the positive and the equalizer bars. In parallel operation, therefore, series field shunts serve only to pass the generator current in excess of that carried by the series coils, and are in no sense voltage adjusters of individual machines with reference to the others.

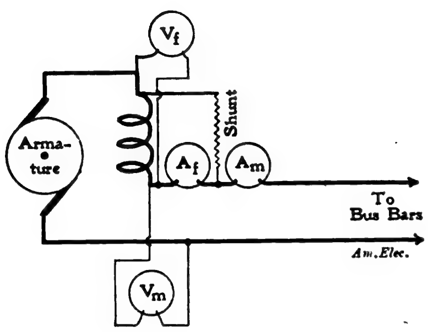

FIG. 4.

When the characteristics of the several dynamos differ, there is generally one value only of the load at which the total current is exactly divided among the machines in proportion to their respective capacities. It is usual to fix the full load output as that at which this proper load division shall take place. With loads less than the full rated output, the fact that the several currents are not exactly proportional to the capacities of the various generators is of little moment, since each one of the machines is running at less than its normal rated output, and the total efficiency of the station is not appreciably affected if the output of some machines is 80 per cent. and of others 70 per cent. of their normal rating.

With these facts understood it is practicable to pass to the consideration of a definite case of paralleling several generators having different characteristics. Assume that in rearranging and changing over machinery there are available for station equipment five generators as follows:

No.	Kw.	Volts. No load.	Volts. Full load.
1	250	500	545
2	250	500	552
3	440	500	550
4	1100	500	540
5	1500	500	550

It is desired that the station e.m.f. shall be 550 volts at full load. Of the above tabulated machines, one is above and two are below this value.

A simple test is necessary both to discover the series field current required to bring the e.m.f. of each machine to the prescribed voltage and to determine the resistance of the series coils, which also must be known. To make this test, one ammeter is put in circuit with the series field, another put in the main circuit, a high reading voltmeter connected across the negative brush and the outgoing terminal of the series winding, and a very low reading voltmeter is connected across the series winding. Fig. 4 shows the connections of these instruments. The machine is run at normal speed and loaded up to its normal capacity, as shown by the ammeter A_m. Adjust the shunt until the e.m.f., as shown by voltmeter, V_m, is 550 volts. Record the readings of A_f, A_m and V_f, V_m being in each case 550 volts.

Tabulating these readings on the above generators the following data are obtained:

TABLE II.

No.	Kw.	Amperes: Total.	Amperes: In field winding.	Amperes: In shunt strip.	V_f = volts across field.	R_f = field resist.
1	250	458	390	68	2.69	.0069
2	250	453	338	115	1.284	.0038
3	440	800	800	0	4.32	.0054
4	1100	2037	1905	132	1.065	.00056
5	1500	2710	1850	860	1.665	.0009

The value of the current through the shunt strip is found, of course, by subtracting that through the field winding from the total, and the resistance of the field winding is found by dividing the field drop, as shown by V_f, by the current, A_f.

Looking over the sixth column it is seen that the greatest drop at full load field current is that of machine No. 3, which is 4.32 volts. This must be the voltage between the equalizer and positive bus-bars as a lower e.m.f. would not pass the required current through the series field winding of this machine. This e.m.f., however, will be too high for the windings of the other generators, and resistances must be put in series with their series field windings to prevent excessive currents from flowing through them.

Going back to Table II and computing the resistance which would allow the proper current to flow through each field winding, as given in the table, with 4.32 volts impressed across it, the following values are obtained for R_m and R_s, in which R_m is the total resistance which the current will pass through under 4.32 volts impressed, and R_s is the external resistance to be inserted in series with the compound winding, this being, of course equal to the total resistance minus the field winding resistance.

TABLE III.

No.	Series field current; I_f	$R_m = \frac{4.32}{I_f}$	Series resistance; R_s
1	390	.01115	.00425
2	338	.01278	.00898
3	800	.0054	0
4	1905	.002275	.001715
5	1850	.00234	.00144

If an external resistance equal to that computed for any one machine be put in series with the compound winding of that machine, and all the dynamos be so equipped, the total output will be proportionately divided among the various machines at full load.

The total output of the station is the sum of the individual outputs in column 3, Table II, which is 6458 amperes, while the current required in the series fields is the sum of the currents in column 4 of the same table, or 5283 amperes. The difference between these two, or 1175 amperes, must pass through a shunt from the positive bus-bar to the equalizer. It makes no difference where along the length of the bus-bars this shunt is placed—if the bus-bars be not too small so that the drop along them will not be excessive. The resistance of this shunt must be

$$\frac{4.32}{1175} = .00368 \text{ ohm.}$$

The diagrammatic layout of the arrangement as computed, is shown in Fig. 5.

While this system will work perfectly, and each of the machines will take up its share of the full load, the I^2R loss in the series fields and the shunt is excessive. Assuming that the average station load is 25 per cent. of full load for six hours, 50 per cent. for six hours, 75 per cent. for eight hours, and 100 per cent. for four hours, the volts drop for each of these are 25 per cent., 50 per cent., 75 per cent. and 100 per cent. respectively, of 4.32, or 1.08, 2.16, 3.34 and 4.32 volts. The currents at each of these percentages of load are 1614, 3229, 4843 and 6458 amperes, respectively, and the total energy loss is therefore $6 \times 1.08 \times 1614 + 6 \times 2.16 \times 3229 + 8 \times 3.34 \times 4843 + 4.32 \times 6458 = 291.33$ kilowatt-hours per day. At 1 cent per kilowatt-hour this costs $2.91 1-3 per day or about $1060 per annum. Obviously, if the voltage drop between the positive and equalizer bus-bars be reduced, the energy loss, and consequently, the money wasted by it, will be proportionately decreased. Looking over Table II it is seen that the next lowest voltage drop is for machine No. 1, and is 2.69 volts. If all the dynamos were arranged to work with a voltage drop of 2.69 volts between the positive and the equalizer bus-bars the total energy loss per day would be

$$\frac{291.333 \times 2.69}{4.32} = 161 \text{ kilowatt-hours, and}$$

its annual cost at 1 cent would be $1.61 ×

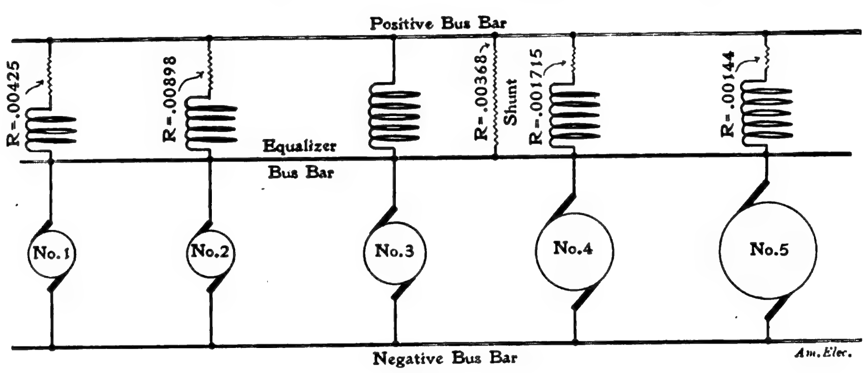

FIG. 5.

365 = \$588. The annual saving therefore—assuming that some alteration could be made in the 440-kw. machine—would be \$472, which is capitalization on about \$8000. Therefore, it would be better to sell dynamo No. 3 for whatever it would bring and purchase a new machine, rather than attempt to work it in parallel with the others if it cannot be so altered as to require a less voltage across its series fields at full load. This question is a commercial, not a technical one.

In all probability, however, it would be found that there is room on the field magnet poles to add more series winding. If so, it is only necessary to wind on another series coil over each existing one, the new and old coils having the same number of turns and connect the two in parallel. This produces an equivalent series coil of diminished resistance.

To determine the cross section of the conductor in the additional winding, assume a reasonable mean length of turn and find the ratio of this length to the mean length per turn of the existing winding; represent this ratio by r. Let b = voltage drop through the existing winding at full load, c = desired voltage drop through new and old windings in parallel, x = cross-section of new conductor, and a = cross-section of the old. Then $x = a \times r \dfrac{b-c}{c}$.

As an example, take the 800-kw. generator having a drop of 4.32 volts across the series field winding with 800 amperes flowing through it, and let it be required to wind on additional copper of such cross-section as to reduce the drop to 2.69 volts with same current and same effective turns. The cross-section of the series conductor on the machine is 600,000 cir. mils. The mean turn of the existing winding is 3.25 feet in length; assuming that of the additional winding will be 3.6 feet, the ratio, r, is $\dfrac{3.60}{3.25} = 1.11$; then $b = 4.32$, $c = 2.69$, and $a = 600{,}000$, and by the foregoing formula the cross-section of added conductor, $x = 600{,}000 \times 1.11 \times \dfrac{4.32 - 2.69}{2.69} =$ 403,596 circular mils. These two windings connected in parallel will give 2.69 volts drop when 800 amperes pass through them. Since this additional winding can be put on for a very small cost, it should be done if possible and the 440-kw. machine retained, unless its efficiency is too low. If 2.69 be adopted as the voltage drop between the positive and equalizer bus-bars, the resistances to be put in series with the series fiel windings of machines 2, 4 and 5 are computed as previously outlined.

Referring again to Table II it will be evident that the series field voltage of 2.69 suggested for adoption is that of machine No. 1, which is of only 250 kilowatts capacity—a small machine as compared with Nos. 4 and 5. Of dynamos Nos. 2, 4 and 5, the highest field drop is that of No. 5, which is 1.665 volts at full load. If this were adopted as the drop between the positive and equalizer bus-bars, a comparison of the field losses at this voltage and at 2.69 volts, on the basis already stated, would show \$225 annual saving for the lower voltage drop, and if the machines were of similar kind with like characteristics, it would pay to rewind both dynamos Nos. 1 and 3 to give a drop of 1.665 volts at full load and change the resistances inserted in the series fields of Nos. 2 and 4, and the shunt resistance, to suit this changed value; but in machines which differ as greatly as do these, the division of the load is not stable nor well defined unless there be an appreciable voltage drop between the equalizer and positive bus-bars, as the small drop in the bus-bars themselves becomes large as compared with the drop between them. In the present case, therefore, it would be best to adopt 2.69 volts as the drop between the positive and the equalizer bus-bars.

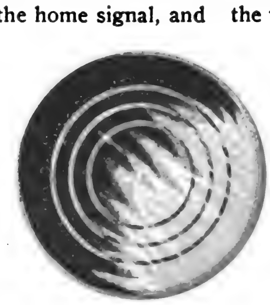
AUTOMATIC BLOCK SIGNALS.

BY RALPH SCOTT.

Complete Normal Clear Circuits.

In Fig. 62 the arrangement of a normal clear system, giving complete protection for a double track system, with another line crossing, is shown. The block between signal 7 and signal 8 is very long in this case. The reason for assuming such a long block is to prevent confusion in the circuits.

Describing the apparatus at signal 3, there is the signal battery *i*, connected to the home board through the contact armature *a*, of the relay *h*, and also connected to the distant board through the neutral armature *b*, and the polarized armature *c* of the track relay *e*. The track battery *f* is connected to the block *A* through the current reverser *g*, which is operated by the home board of this signal. The circuit closer *d* is operated by the home signal, and connected in series to the distant signal. By means of this circuit closer, when the home signal moves to danger, the distant signal circuit is also opened.



It is to be remembered in this diagram that *n* are the home signals and *o* the distant signals. At signals 13 and 9, the distant signal is omitted, not being necessary. A polarized track relay *p* has two neutral armatures, the upper one of which forms the indication armature.

In this diagram, crossing *D* is only partially connected, through its track relay, and the switching track *C* is not connected at all, the reason for this being to prevent unnecessary complication.

All the apparatus shown at 10 constitutes what is known as an interlocking tower, this apparatus being all included within the tower 11. The relays *l*, which form the means for electric locking, prevent any conflicting of the signals given out at this tower. In addition to these are the circuit closers *m*, the upper set of which are connected in series with the relay *k*, and some of the wires *P* to *Y*, which, if of sufficient length, are line wires.

These line wires effect the various interconnections between signals 13, 7, 9 and 8 and the interlocking system. *P* connects relay *p* to the track, *Q* connects the signal

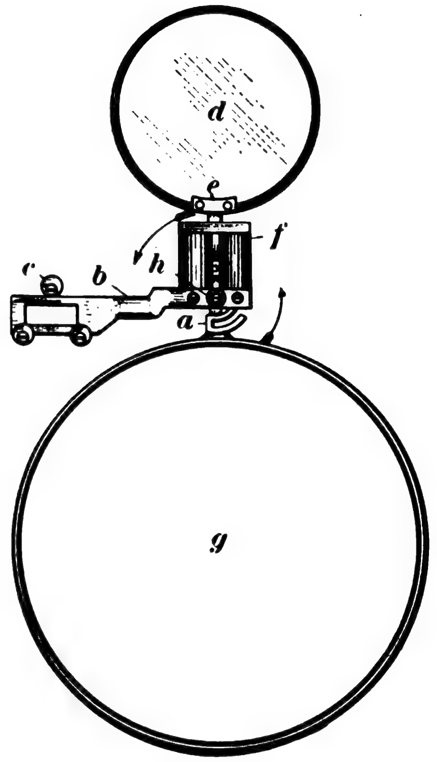


FIG. 63.

battery at 13 with the upper armature of the relay *X*; *R* and *S* form indication wires, while *T*, *U*, *V*, *W* and *Y* perform various functions. The line wire *u*, passing from the top armature of relay *q*, connects battery

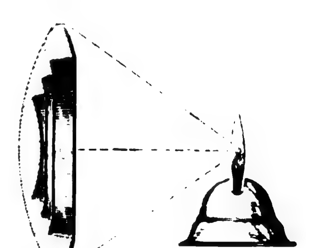

FIG. 64.

s with one side of the signal at 7, the other side of this battery being connected to the signal 7 through the relay at this section. The circuit closer, *r*, operated by the signal 8, opens or closes the circuit of a distantly located signal. The circuit closer *v* is in series with the locking contacts *m*.

From the normal clear circuits which have already been described, the reader may readily trace up and apply the circuits given on this diagram.

12 is a power plant, which is used in many systems. From this power plant line wires pass along the track and to the storage batteries at the various signals. These line wires are connected to the storage batteries through the medium of an electrically controlled or manually operated double throw switch. In many cases, such an arrangement is more economical than the use of primary batteries.

Disc Signal Mechanism.

The mechanism of the disc signal is shown in Fig. 63. The spectacle, *d*, of col-

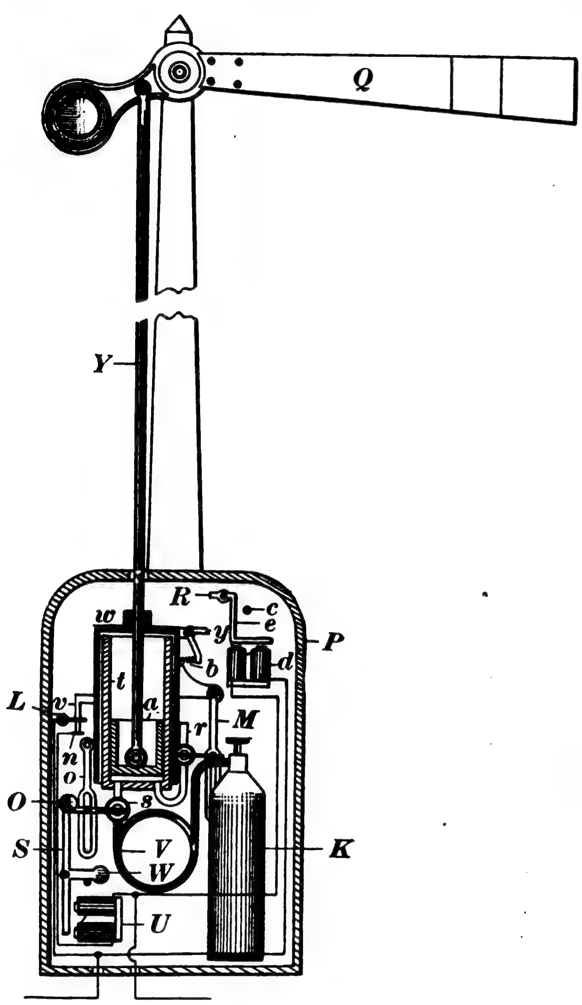

FIG. 65.

ored glass, used for night signaling, and the banner of colored cloth, *g*, used for day signaling, are both fastened to the armature, *a*, of the relay, *f*, by means of the clips, *e*. This armature is so arranged that the continuation of motion embraces a constantly increasing number of lines of force, so that the torque is much greater when the banner has moved to the clear position than at any other time. This is necessary, as the effect of gravity in opposing the torque of the electromagnet is zero in the position shown, and at a maximum when the disc has moved to the full clear position in the direction of the arrows. The armature is adjustably pivoted at *h* and supported by the brass member, *b*, held in place by the washers and screws, *c*.

A section and elevation of the spectacle of a signal is shown in Fig. 64, which also gives the focal distance at which the lamp is located. These lamps are constructed to burn continually for eight days, so that a minimum amount of care and attention are necessary.

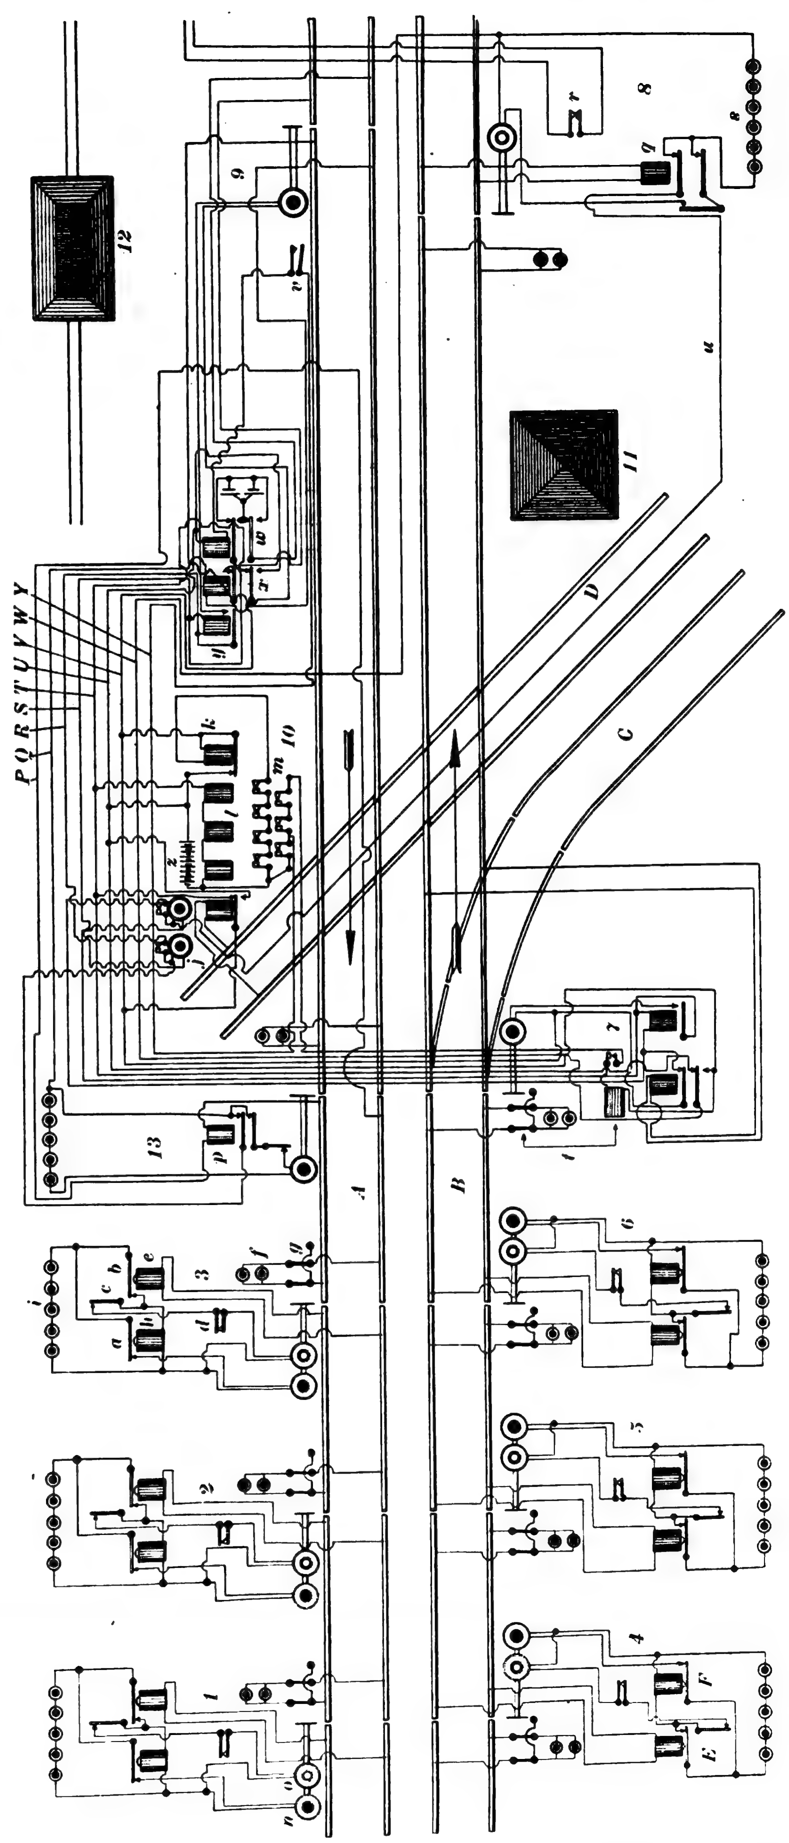

FIG. 62.—DIAGRAM OF CONNECTIONS FOR COMPLETE NORMAL CLEAR CIRCUITS.

The Electro-Gas Signal.

The earliest form of electro-gas signal is shown in part section and elevation in Fig. 65. The usual semaphore, *Q*, is operated by the movement of the rod, *U*. Fastened to this rod, within the housing, *P*,

placed at the base of the signal pole, is the casing, *w*, to which is fastened the circuit-closer, *v*, the pivoted catch, *y*, and the pieces *o* and *M* for shutting off the gas.

The gas flask, *K*, connected by the flexible pipe, *V*, to the valves *s*, contains the operating gas. Two relays, *d* and *u*, connected in multiple, are in the track or line wire circuit, a diagram of which is given later. The circuit of *U* is opened and closed at the pivoted spring contact at *L*, which tends to remain open, unless forced into contact with *n* by the projection on *v*. The contact at *L*, therefore, will be open except when *Q* is at the danger position, as shown.

The catch, *y*, is held in a state of resiliency by the spring *b*, which engages, when the signal is in the clear position, with the end, *R*, of the pivoted member, *e*, which latter is prevented from moving too far upward by the stop, *c*. *e* is held in its lower position by the electromagnet, *d*, which, when energized, and the signal has moved to the clear position, maintains the latter in that position, releasing it when the current ceases.

Relay *U*, by attracting the pivoted armature, *S*, weighted at *W*, allows the weighted handle, *O*, of the valve *s* to drop, thereby admitting gas to the cylinder, *t*. This causes the piston, *a*, to move upward and clear the signal. At the instant that motion commences, the circuit of *U* is broken at *L*, thus allowing *S* to move to its normal position. When *a* has nearly moved to its extreme upper position, the member, *o*, raises the valve lever, *o*, to its extreme upper position, thus shutting off the gas. At the same time, the exhaust valve at *r* is opened by the member, *M*, thus allowing the gas to escape from the cylinder. *a* is held in the clear position as long as the current passes through *d*, as explained above.

The exhaust valve is closed and the admission valve left normal on the return of the mechanism to the normal position, *O* being, therefore, in the position shown in the engraving.

Circuits.

The manner of connecting electro-gas single-mast signals with line wires is shown in Fig. 66. The signals, 1, 2 and 3, have their respective signal batteries, *A*, *B* and *C*, one side of which is connected to these signals. Relays 5, 6, 7, 8 and 9 at the cut sections, of the same number, effect the interconnections. The lower armature of relay 5 is connected to the signal, 1, and to the relay of cut section, 4, the upper armature being connected to the signal battery and the armature of the relay, 6. The lower armature thus serves to connect the battery to its signal, the upper armatures opening the circuit of the signal in whose block the relay occurs. Otherwise, the circuits are somewhat similar to those we have already considered under the normal danger system.

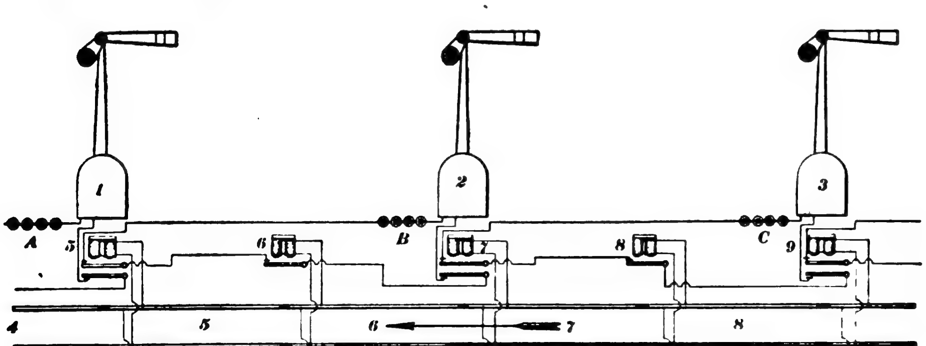

FIG. 66.

Abstracts from Foreign Contemporaries

New Method of Compensating and Compounding Alternators.—In a paper read before the Manchester Local Section of the British Institution of Electrical Engineers, Miles Walker describes a new compensating method for alternators, in which the field excitation is maintained constant and in which use is made of the armature reaction to strengthen the field on load. The illustration shows the arrangement of the generator field circuit. Each pole consists of at least two parts, a saturated part and an unsaturated part. The first is wound with a magnetising coil, and there may or may not be another magnetising coil placed around the whole pole. This second winding may be necessary for varying the normal voltage of the machine. The broad pole is very highly saturated in the region marked with shaded lines, while the narrow pole on the right is unsaturated, and at no load is unmagnetised. The field rotates counter-clockwise, and as the pole depicted in the figure is a south pole, it gives rise to an e.m.f. in the conductors above it, which is in the sense indicated by the crosses, that is to say, away from the observer. Any current in the armature which is in phase or nearly in phase ~~with this~~ e.m.f. will tend to demagnetise the saturated part of the pole and magnetise the unsaturated part. The flux from the saturated part cannot be changed to any great extent, while the unsaturated part becomes highly magnetised by armature reaction and increases the e.m.f. of the armature. The British Westinghouse Company has thoroughly tested this type of machine, and in all cases where the power-factor is not lower than 0.85 they find it possible to make a machine hold its voltage from no load to full load. In the great majority of cases in which alternate-current generators are used, the power-factor is higher than 0.85, so that a compound alternator without commutator or any complications can be supplied. The armature, in increasing the e.m.f., is instantaneous in its action. In cases where the power-factor ranges between 0.9 and 0.95, as in a great number of lighting stations, considerable over-compounding can be guaranteed. The following are the results of a test made on a 150-kw., three-phase generator, 415 to 440 volts, 25 periods, 500 r.p.m. The generator was belted to a shunt-wound, direct-current motor, and loaded on a rack of iron wire (power factor 0.97). With 28 amperes in the main field coils, and no current in the auxiliary field, the voltage was 416 at no load. On throwing on a load of 150-kw., and correcting the speed, the voltage rose to 445 volts, showing a compounding of 6 per cent. between no load and full load. On another test the main field current was diminished and the voltage brought up on the auxiliary field winding. The rise in voltage on load was not so great as before. By fixing the current in the two windings at a suitable figure, it was found possible to make the machine hold its voltage exactly between no load and full load. The generator was then loaded on a 100-kw. rotary converter through transformers. The rotary ran well in parallel, loaded and unloaded, at power-factors varying between unity and 0.7. The synchonising current could be reduced to a value too small to read upon the instruments by adjusting the field of the rotary. When the rotary was loaded so as to produce full load in the generator with unity power-factor, a rise in voltage of 10 per cent. was obtained between no load and full load. At a power-factor of 0.87 the voltage was maintained constant at

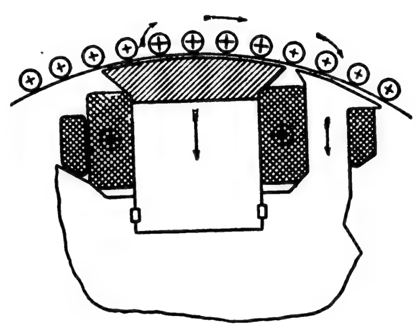

FIG. 1.—COMPENSATING AND COMPOUNDING ALTERNATORS.

all loads. The drawback to this method of compounding is that as the power-factor decreases the magnetising effect of the armature also decreases, but this objection is not so serious as might at first be supposed, for in the majority of cases the generator is carrying all day the greater part of its non-inductive load. Take the case, for instance, of a station supplying principally incandescent lamps. All day the generator has to supply the magnetising current to transformers, and when the load comes on suddenly in the evening the power-factor increases, so that a generator of the type described would have exactly the right kind of regulation. Similarly, where a generator is loaded with induction motors running light, a load on the motor increases the power-factor, and again the generator behaves well. In cases where sudden and large draughts of power at low power-factor are required, this type of generator would not be suitable. It may appear at first sight that a generator with a field magnet shaped as shown in the illustration would not have a good e.m.f. wave form. It has been found that by proper design the wave form at full load can be made to approximate very closely a sine wave; in fact, more closely than the wave form of the old simple type generator. At no load the wave form will not depart much from the true sine wave, but will have a slightly peaked form—the form, in fact, which has been found to be most economical with transformers working on light loads.

The Insulation of Armature or Other Coils for High-Tension Apparatus.—J. S. Highfield contributes to a recent number of the London *Electrician* an article relating to troubles experienced from time to time by the breakdown of the insulation of armature coils in alternators built for 6000 volts and upwards. In the case of most machines the copper is insulated from the core plates by means of a solid mica or micanite tube, having a dielectric strength capable of resisting at least four times the working pressure; and the ends of the tubes are carried out quite clear of the frame, so that there can be practically no chance of sparking taking place from the ends of the coils to the frame. Careful experiments were made to determine the exact cause of the trouble. The coils of one machine in question were insulated between turns with varnished cotton braiding, and without by the micanite tubes above mentioned, the micanite being of the best possible quality, and the tubes being exceedingly well built. The coils were formed by winding the ribbon, of which the conductors consist, through two tubes. The ends of the coils, where they emerge from the tubes, were protected by slips of mica and wrappings of the well-known ordinary Empire cloth with prespahn, and finally black-taped to give some mechanical protection, the workmanship being all that could be desired. Upon examining a coil, by splitting open the tube, it was at once apparent that serious corrosion had been taking place, the braiding being practically destroyed, and the copper covered with a green deposit. An inspection of the ends of the coils showed that the Empire cloth near the tubes was completely rotted, being quite damp and having a strong acid reaction, but the braiding was in fairly good order, although also damp and having acid reaction. Upon opening some of the tubes, it was discovered that, in some of the coils, the whole of the braiding was rotted away, the copper being covered with a green deposit, which, upon analysis, was found to be nitrate of copper; there also appeared to be a certain amount of free nitric acid present. In the Empire cloth, at the ends of the coils, sulphuric acid was found. As the materials were all of the best, it was immediately suspected that the nitric acid was formed by brush discharge causing ozonization of the air and in order to make quite sure of this fact, one of the tubes was carefully cleaned, and a strip of bright copper gauze covered with pure filter paper was placed inside the tube, the outside of the tube being covered with tin-foil connected to earth, the copper being connected to the supply of 10,000 volts—the paper was not specially dried. Ozone was produced in considerable quantities at once, and in about one week a considerable amount of green deposit of nitrate of copper was formed on the copper gauze, and free nitric acid on the filter paper. The cause of the breakdown of the coils was therefore quite clear. Brush discharge took place on the inside of the coils from the copper to the mica, and, with the nitrogen from the atmosphere and moisture from the air, produced nitric acid. The acid worked itself out of the tube, and, combining with the gympsum in the Empire cloth or braid, formed sulphuric acid at the ends of the coils. It was found that the coils at the end of the machine were in a worse condition than the ones lower down, and the degree of corrosion was somewhat variable, pointing to the fact that some of the coils were dryer than others, there being no doubt that the rate of corrosive action was enormously increased by the presence of free moisture. From researches made it would appear that in any machines, even down to as low a pressure as 2000 volts, trouble from the above mentioned cause might be experienced. Careful vacuum drying of the coils during the process of insulation would undoubtedly serve to delay the breakdown of the machine, but it certainly seems that no method of insulation admitting air between the copper, iron and insulation can produce a machine that will last for all time. The only proper method is to fill in the whole of the space from copper to iron with insulating material, so as to entirely exclude air. The mere sealing of the ends is not likely to be a remedy, as considerable heat is generated in the armature; this expands the air in the coils, and on cooling a slight vacuum is formed which encourages the entrance of fresh air bringing with it some quantity of moisture. The investigation showed the necessity of carefully insulating the last two or three coils at the end of the armature where the pressure is greatest. It was found that, on the last coil particularly, the copper was pitted in places, and opposite each little lump the braiding was punctured.

Cylindrical Water-Tube Boiler.—Fig. 2 herewith illustrates a Cummins vertical water-tube boiler, a description of which is given in a recent issue of *The Engineer*, of London. The boiler consists of an upper and lower drum, connected by straight vertical water tubes. The furnace is situated underneath the lower drum, which has a central flue, through which the gases pass to the combustion chamber. The combustion chamber is formed by the space between the upper and lower drums above this flue, which is, of course, free of water tubes. After leaving the combustion chamber the gases are compelled, by means of a curved baffle plate, to divide into two streams, each stream having to travel a long distance among the water tubes before passing away to the funnel. The water tubes are of comparatively large diameter, $2\frac{1}{2}$ ins., are straight, all of one length, and secured in the tube plates in the usual manner by expanding. The upper drum is made of sufficient height to allow the water

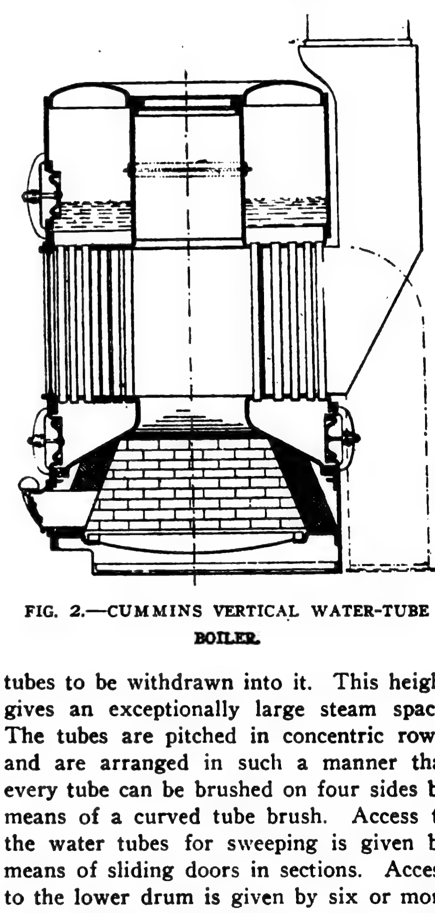

FIG. 2.—CUMMINS VERTICAL WATER-TUBE BOILER.

tubes to be withdrawn into it. This height gives an exceptionally large steam space. The tubes are pitched in concentric rows, and are arranged in such a manner that every tube can be brushed on four sides by means of a curved tube brush. Access to the water tubes for sweeping is given by means of sliding doors in sections. Access to the lower drum is given by six or more large manholes. The upper drum is made annular like the lower one, the central space being utilized for a superheater when such is required. The lower casting carrying the fire-bars is lined with fire-bricks. The volume of the combustion chamber has been arranged to be equal to that of a return-tube marine boiler of the same power. The combustion chamber is surrounded by water tubes, so that the intense radiant heat will be at once taken up by them. The furnace is lined with fire-brick, which is a great aid to good combustion. The fire-brick also protects the lower plate of the drum from

the direct heat of the fire. A fire-brick lining is also very essential for successfully burning liquid fuel. The furnace can be readily adapted for forced draught or mechanical stoking. The total distance traveled by the gases in this boiler is considerably more than in the case of a return-tube marine boiler. The water circulation in this boiler is quite positive, and, some of the tubes in the outer rows act as down-comers. In this boiler, by the removal of seven doors, the whole of the internal part of the boiler is perfectly accessible for examination, cleaning, or repairs. Complete access is given to both ends of the tubes, and any tube can be expanded, or cut out and renewed, without disturbing any of the others. All the internal landings of the joints can be re-caulked if necessary, and any tube can be plugged without emptying the boiler. In the same manner all the external landings of the riveted joints are accessible for re-caulking. The results of a test of a boiler of this description are given below:

PRELIMINARY TEST OF CYLINDRICAL WATER-TUBE BOILER (CUMMINS' PATENT.)

Conditions:—Lower drum not lagged, steam blown off at safety valve, cold feed, no superheater fitted.
Duration of trial: 6 hours.
Quality of fuel: Unscreened Welsh.
Class of firing: Hand.
Heating surface: 774 square feet.
Grate surface: 23.7 square feet.
Ratio: 1.32.
Steam pressure: 175 lbs.
Draught at base of funnel: 6 ins.
Temperature of feed: 60 deg. Fah.
Temperature of gases leaving boiler: 597 deg. Fah.
Temperature of steam leaving safety valve: 320 deg. Fah.
Corresponding superheat: 108 deg. Fah.
Fuel per hour: 448 lbs.
Fuel per square foot grate per hour: 19 lbs.
Fuel per square foot heating surface per hour: .58 lb.
Water per hour: 3,948 lbs.
Water evaporated per lb. fuel: 8.81 lbs.
Water evaporated per square foot heating surface: 5.13 lbs.
Water per lb. fuel from and at 212 deg. Fah.: 10.6 lbs.
Water per square foot heating surface from and at 212 deg. Fah.: 6.2 lbs.

During the trial the water level was maintained constant by the Fleuss automatic feed regulator. This apparatus controls the steam working the boiler feed pump, and has been in use on the above boiler for six months, during which time neither the boiler check valve nor the feed pump steam valve have been touched.

Patent Absorption Dynamometer.—A simple dynamometer is described in the London *Electrical Review*. It is especially suitable for measuring the brake-horse-power of electric and petroleum motors, and has a range of from ¼ to 20 horse-power. The power is absorbed by revolving vanes in air. Vanes of three different sizes are supplied, and the apparatus can be clamped on spindles from ¾ in. to 1⅜ in. diameter. The dynamometer is compact and simple, and goes into a box 24 in. by 9½ in. by 6 in.; the weight complete, including the box, is about 22 lbs. The essential feature of the dynamometer is the simplicity and quickness with which the brake-horse-power can be obtained. It has been calibrated for speeds up to 2000 r.p.m. The dynamometer is clamped on the spindle of the machine to be tested, and the vanes are adjusted to such a radial position that the motor runs at the required speed when under load. Knowing the speed, and the position and size of the vanes, the horse-power can be immediately obtained from the calibrated results which are supplied with the dynamometer.

Arc Lamp Suspension.—The London *Electrical Review* shows an extremely ingenious and simple form of hook for suspending an arc lamp, which was originally described in *Génie Civil*. The suspension rod of the lamp ends in a ball, *S*, which, when the lamp is in place, rests in the hook, *C*, as shown in Fig. 3. Upon hauling on the suspension rope, *A*, the ball slides along the under side of the inclined plane, *P*, and presses the hook, which is pivoted at *B*, to one side. When the ball passes through the enlargement at the top of the hook the latter swings forward

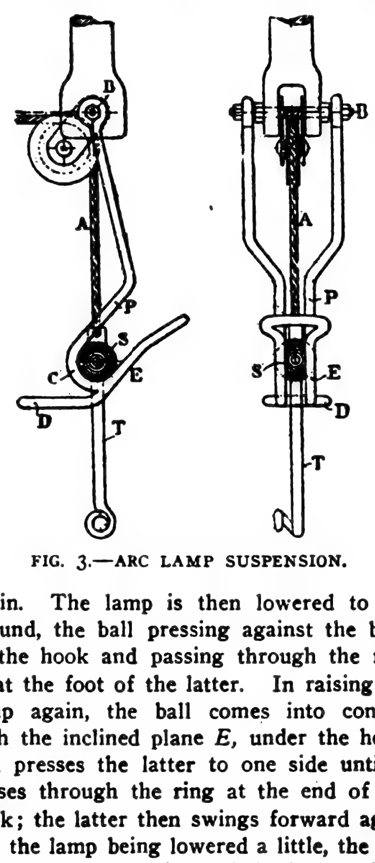

FIG. 3.—ARC LAMP SUSPENSION.

again. The lamp is then lowered to the ground, the ball pressing against the back of the hook and passing through the ring *D* at the foot of the latter. In raising the lamp again, the ball comes into contact with the inclined plane *E*, under the hook, and presses the latter to one side until it passes through the ring at the end of the hook; the latter then swings forward again and the lamp being lowered a little, the ball descends into the bight of the hook, where it is securely held. As the cord is always retained within the hook, it can never get out of place or be otherwise deranged.

Governor for Turbines.—A new method of governing turbines, has been installed in the hydraulic installation of Bournillon, a description of which appears in *Engineering*, of London. In this apparatus the essential feature is a pump, *P*, with a constant delivery, which compresses water into the chamber, *K*, and the system of piping, *m*, and can only escape into the tank, *A*, when the valve, *S*, is raised. The area of valve opening is regulated by a centrifugal governor. It is evident that for every position of the valve there is a corresponding pressure, *h*, in the compression chamber of the pump, and it is given at each instant by the relation $Q = k\,S\,\sqrt{2\,g\,h}$. Where *Q* is the quantity of water delivered by the pump, *k* is a coefficient of contraction, and *S* is the section of the orifice at the moment of consideration. As the velocity of the governor increases, the orifice is gradually diminished, and when closed

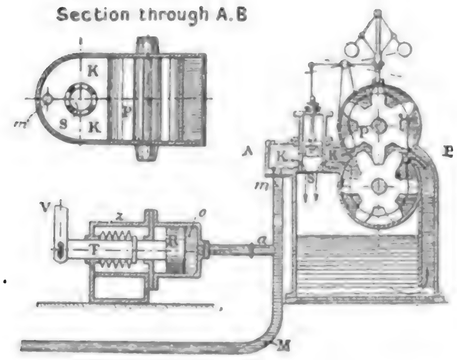

FIG. 4.—TURBINE GOVERNOR.

the water cannot escape into the chamber, and is therefore forced through the pipe, *m*, the pressure increasing until the speed again becomes steady; the valve then opens slightly, and the pressure at the delivery of the pump ceases to rise. At this moment there is a definite pressure corresponding to the position of the valve. It is obvious that the pressure created in the compression chamber is exercised on the piston, *R*, and since the force exerted on the latter is counterbalanced by the spring, *Z*, which compresses in proportion to the load it supports, it becomes evident that the piston occupies a certain position for each valve of the pressure, *h*, of the compressed liquid. Hence it follows that for every position of the governor there is a corresponding pressure of the liquid and position of the piston, both positively determined. The piston is connected by levers, *T* and *V*, in a rigid manner with the regulating mechanism of the turbine, and there can therefore be only one possible position for the sluice valve at any moment for a given position of the governor. Supposing that a motor turning at a uniform angular velocity, V_0, is unloaded abruptly, then the speed instantly commences to increase, and would take a working speed, V_1, if there was no governor. But in this case the latter rises when the velocity increases, and consequently the valve, *S*, closes, causing the pressure, *h*, to increase, and the springs to compress, thus moving the piston-rod, *T*, and shutting the sluice valve of the turbine. This action of the valve ceases immediately the couple of the motor becomes equal to the couple of resistance; in other words, all is again in equilibrium at a new angular velocity, V_2, which is a little higher than the initial velocity, V_0. If, on the other hand, the load is applied suddenly, then exactly the reverse of this operation takes place. It will be seen that everything acts as if the sluice valve was controlled directly by the governor. The governor can be so designed as to give the valve a quick action and further, it is possible to make it such that the speed variation, $V_2 - V_1$, can be made as small as desired. By means of a simple arrangement V_2 can be reduced to the initial velocity V_0 when it is necessary to keep the speed quite constant, however much the load on the motor may fluctuate. The governor can be worked by hydraulic power when there is a sufficient fall of

water, otherwise the water under pressure must be supplied from an accumulator, the necessary pressure being obtained by means of pumps, or the method illustrated in the diagram may be employed.

The Tantalum Incandescent Lamp. — In a paper read recently before the Elektrotechnische Verein at Berlin, Drs. W. von Bolton and O. Feuerlein describe the new tantalum lamp made by Siemens & Halske. After experimenting for a number of years in the metal tantalum itself and also on the shape and size of lamp the form shown by Fig. 5 herewith was finally arrived at. This shows a 110-volt, 25-c.p. lamp using 1.5 volts per Hefner candle-power. In this form, differing from most of the previous constructions, the central support consists of a short glass rod carrying two lenses into which the arms, bent upward and downward in the shape of an umbrella, are cast. The upper star has 11, the lower

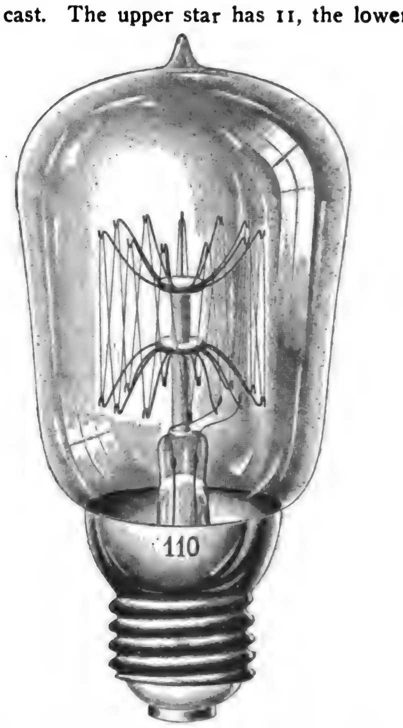

FIG. 5.—TANTALUM INCANDESCENT LAMP.

12 arms, each upper arm being in a vertical plane midway between the vertical planes in which two adjacent lower arms lie. Between these arms, which are bent into hooks at their ends, the entire length of the filament is drawn zigzag. Its extremities, held by two of the lower arms, are connected with the foot of the lamp by means of platinum strips. The standard type for 110 volts, 25 Hefner candle-power, and 1.5 volts per candle-power, has a filament 650 mm. long and 0.05 mm. in diameter. The weight of this filament is 0.022 grams, so that about 45,000 lamps contain together 1 kilogram of tantalum. The shape of the glass globe is adapted to the frame described above. Care has been taken to make it of a size not exceeding the usual maximum dimensions of common incandescent lamps of the same candle-power. This shape offers a number of noticeable advantages. In the first instance it is very stable, and will stand severe shocks without damage to the lamp. A considerable number of such lamps were sent across the sea to test their resistance to the hardships of transport, and came back unhurt, although they had been packed just like common incandescent lamps, and no special care had been taken at any time in their handling. The lamp burns, of course, in any position, and can therefore be held in any kind of fitting. The light is white and agreeable; its effect is particularly steady if the lamps are provided with ground glass globes. Numerous trials for lengthy periods of time, at rates varying within the range of 1 to 3 watts per candle-power, have proved the vast superiority of the tantalum lamp over the carbon filament lamp under equal electric and photometric conditions. Expressing this fact in figures, the authors state that the tantalum lamp consumes about 50 per cent. less current at the same voltage, with the same intensity of light and the same useful life, than the carbon lamp does, or that it supplies about double the light of the carbon lamp with the same consumption of current; while at the same economy the life of the tantalum lamp is several times that of the carbon type. Moreover, at an initial load of 1.5 volts per Hefner candle-power the tantalum lamp has an average life quite sufficient for all practical requirements, so that this rate of consumption has been standardized for the 110-volt lamp. Trials at a load of 1 watt per Hefner candle-power also proved that the lamps had periods of life of several hundred hours, but in that case the lamps were very sensitive to variations of pressure, and often showed an early decrease of illuminating value. The *useful life* of the tantalum lamp—*i.e.*, the life within which it loses 20 per cent. of its initial illuminating value—averages between 400 and 600 hours at 1.5 watts per Hefner candle-power; some specimens have proved to have a *useful* life of more than 1200 hours. The *absolute* life amounts to an average of 800—1000 hours under normal working conditions. Further, the tantalum lamp blackens but little, unless it has been strongly overheated during work in consequence of partial short-circuiting of the filament. It is very interesting to observe the behavior of the tantalum lamp during the whole course of its life. The first fact worthy of note is that, like some carbon lamps, the illuminating value increases at the beginning, generally after a few hours, by 15 to 20 per cent. In the same way the consumption of current rises by about 3 to 6 per cent., while the consumption of power drops to 1.3 to 1.4 watts per candle-power. After that, the illuminating value gradually decreases, while a corresponding increase of the consumption of power occurs. The average behavior of the 25-c.p. lamp at 110 volts, with reference to its various periods of life is shown in the accompanying table.

Life hours.	Intensity of light Hefner c. p.	Consumption in amperes.	Watts per Hefner c.p.
0	25—27	0.36—0.38	1.5—1.7
5	28—31	0.37—0.39	1.3—1.5
150	25—27	0.36—0.38	1.5—1.6
300	22—24	0.36—0.38	1.6—1.7
500	20—22	0.36—0.38	1.9—2.0
1000	18—20	0.35—0.37	2.1—2.2

The initial increase of illuminating value and of current consumed, is, doubtless, caused by a change in the structure of the tantalum wire, this change being accompanied by a reduction of resistance, and, consequently, of the phenomena resulting therefrom.

Measurement of Vacuum.—The London *Electrical Review* contains an abstract of a paper delivered by C. Turnbull at Newcastle, on the measurement of vacuum. The vacuum gauge in common use measures the difference between the condenser pressure and the atmospheric pressure. It is, therefore, necessary to read the barometer as well as the vacuum gauge to get at the true result. What is required is an instrument which will fulfil the following

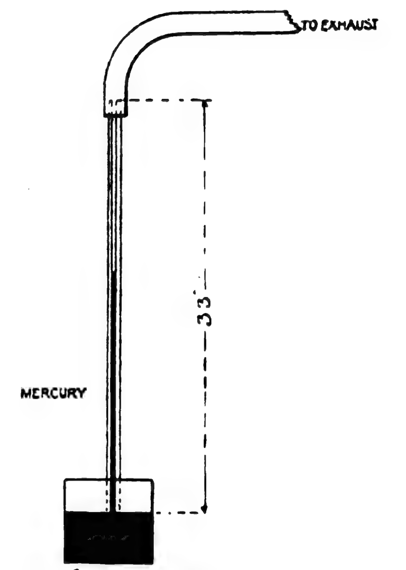

FIG. 6.—MEASUREMENT OF VACUUM.

conditions: (1) It must show the actual pressure in the condenser quite independently of the pressure of the atmosphere; (2) It must be quite accurate in its readings, and not liable to go wrong. The first requirement would be met by an ordinary Bourdon gauge with an exhausted tube (or a similar arrangement to that used in the aneroid barometer), but with the case of the instrument connected to the condenser. This will measure the actual pressure at the exhaust, quite independently of the pressure of the atmosphere. Another and perhaps better way is to make use of the ordinary mercury barometer, only it must be connected up properly. As ordinarily used (Fig. 6) the mercury column balances the difference between the condenser pressure and that of the atmosphere. If it is connected, as in Fig. 7, the mercury column will show simply the actual pressure in the condenser, and quite accurately. When the mercury rises 4 in. in the tube, it

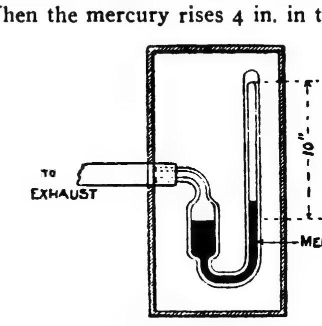

FIG. 7.—MEASUREMENT OF VACUUM.

means that there is a pressure in the condenser which has an effect upon the back of the piston of a reciprocating engine as if the piston were lifting a layer of mercury 4 in. deep. For most purposes with the in-

strument, as in Fig. 7, a 10-in. tube is quite long enough, for this will show a vacuum as low as 20 in. It is to be noted that the reading of any vacuum gauge is materially altered by its position. If it be placed low down, then water will collect in the tube leading to it and the weight of the column of water will affect the reading. Probably this fact often accounts for the difference of reading between the gauge on the engine exhaust pipe and the gauge on the condenser, as much as the drop of pressure between the two due to loss in the connecting pipes.

FAN MOTORS FOR 1905

American fan motors have become so thoroughly standardized that but few changes have been made this year, and extremely few really new machines have been brought out. The construction of the unchanged machines has been described so often and so thoroughly before that it is deemed inadvisable to do more in the present article than to give brief descriptions of

FIG. 1.—G. E. COMMUTATOR TYPE, ALTERNATING-CURRENT FAN MOTOR.

new fans, and point out improvements in the old ones.

The General Electric Company has brought out only one new fan-motor this

FIG. 2.—G. E. COMMUTATOR TYPE ALTERNATING-CURRENT FAN MOTOR DISASSEMBLED.

year, but its line has been extensively revised and improved. The new machine is a commutator alternating-current motor, similar in appearance to the well-known G. E. direct-current fan-motor. Fig. 1 shows the machine in perspective, and Fig. 2 is a view of its disassembled component parts. The field magnet is, of course, built up of steel laminations, and these are mounted in

FIG. 3.—G. E. INDUCTION ALTERNATING-CURRENT DESK FAN MOTOR.

a cast-iron housing. The magnet is bipolar and is provided with two machine-wound and individually-insulated coils, as indicated in Fig. 2. The armature is of the slotted drum type, machine-wound, and provided with the ordinary direct-current commutator. The insulation of both armature and commutator is of the same quality as that used in the standard dynamos and motors of larger sizes. The brushes are of carbon, of rectangular cross-section, and they are fed through box-holders by pivoted fingers and helical springs. The holders are mounted on a ring of insulating material, as shown in the foreground of Fig. 2, and this ring is screwed to bosses on the inner side of the journal bracket or yoke. This journal bracket is independent of the enclosing end-cap of the machine; the latter is of thin metal and is held in place by two screws. Consequently, the machine may be exposed for inspection and adjustment in its running condition, or while in operation. The bearings are lubricated by means of the familiar under-feed cups.

This machine is built for operation on either 25-cycle or 40-cycle circuits at 110 volts. The fan is 12 in. in diameter, and the motor drives it at full speed with 90 watts at 25 cycles or 94 watts at 40 cycles. The full speeds are 1700 and 1900 r.p.m., respectively, at the frequencies named. The motor is equipped with a six-point speed-regulating switch. Either the swivel and

FIG. 4.—G. E. INDUCTION ALTERNATING-CURRENT BRACKET FAN MOTOR.

trunnion mounting shown in Fig. 1 or the rigid mounting shown in Fig. 2 is furnished.

The company also makes the line of induction fan-motors for circuits of 60 cycles and higher frequencies which was described in our annual fan-motor article last year. These are built with 12-inch fans with either swivel or swivel and trunnion mounting, for desk service, and 12-inch and 16-inch fans with swivel and trunnion mounting in desk and bracket types. An 8-inch fan, with special suspension for telephone booths, is also built. The casings of the desk and bracket motors have been improved in appearance since last year, as reference to Figs. 3 and 4 will indicate, and six-point regulating switches have been substituted for the three-point switches used heretofore. The speeds and power values are as follows: 12-inch fans at 60 cycles, 1500 r.p.m. and 78 watts; at 125 cycles 1470 r.p.m. and 84 watts. The 16-

FIG. 5.—G. E. DIRECT-CURRENT FAN MOTOR.

inch fans at 60 cycles, 1570 r.p.m., and 178 watts; at 125 cycles, 1390 r.p.m. and 178 watts.

Fig. 5 illustrates the General Electric direct-current fan-motor for the present season. The field magnet is not laminated, as

heretofore, but is a single casting of extra soft iron. The field-magnet coils are wound in bobbins and subjected to the usual rigorous insulating and baking processes. The coils are held in place by means of spring bows, as shown in Fig. 6. The armature, Fig. 7, requires no description. The brush mounting partially shown in Fig. 5, is very similar to that of the new alternating-current machine already described, the brushes being fed in boxes by spring-actuated fingers and the boxes being mounted on a support of insulating material screwed to the journal bracket. As in the case of the

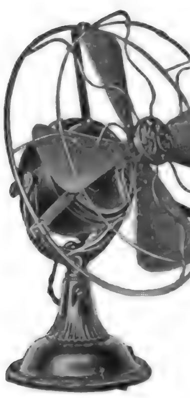

FIG. 8.—G. E. DIRECT-CURRENT DESK FAN MOTOR.

alternating-current fan also, the enclosing end-caps are of thin metal, removable with-

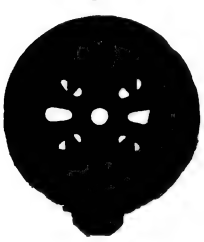

FIG. 6.

FIG. 7.

out disturbing the working parts of the machine.

The 12-inch fans run at 900 r.p.m. with 38 watts, 1200 r.p.m. with 45 watts and 1500 r.p.m. with 60 watts. The 16-inch fans run at 900 r.p.m. with 65 watts, 1200 r.p.m. with 85 watts, and 1500 r.p.m. with 100 watts. Both sizes are built with swivel and trunnion mounting in the desk and bracket

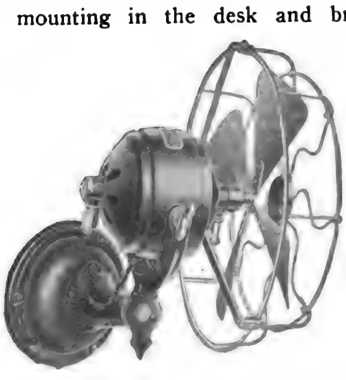

FIG. 9.—G. E. DIRECT-CURRENT BRACKET FAN MOTOR.

types, and the 12-inch fan is also built with rigid pedestal mounting All are made for either 115 or 230 volts. Figs 8 and 9 illustrate the pedestal and bracket mountings with swivel and trunnion. A direct-current motor is also built for telephone booth service. This machine has an 8-inch fan and runs at 1200 r.p.m. It is made for operation directly on a 115-volt circuit or in series with a 110-volt, 16-c.p., 55-watt incandescent lamp on a 115-volt circuit.

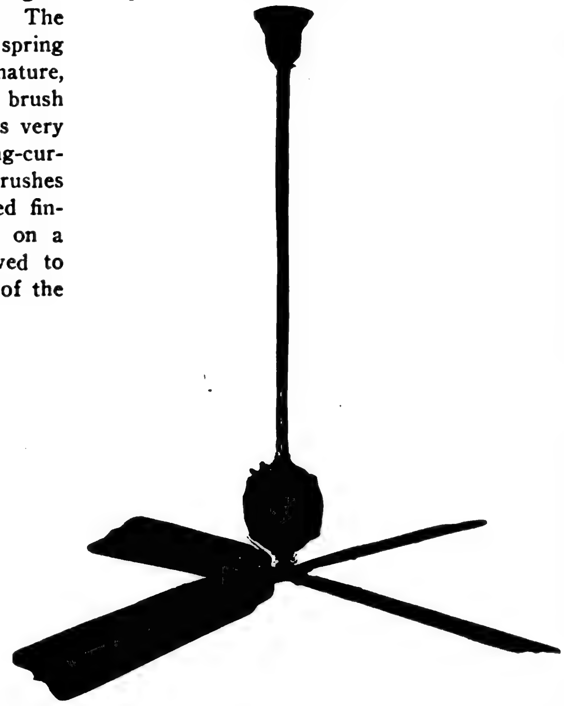

FIG. 10.—G. E. DIRECT-CURRENT CEILING FAN MOTOR.

The General Electric Company also continues its well-known line of three-speed ceiling fan motors for direct-current circuits of 115 or 230 volts, and the "Radial" fan-motor brought out two years ago. The ceiling fan line has been enlarged, however, to the extent of a single-speed machine with a 56-inch sweep running at 200 r.p.m. This motor is illustrated by Fig. 10. It is wound for either 115 or 230 volts.

The Dayton Fan & Motor Company, Dayton, Ohio, has added to its line the new "Dayton" fan-motor shown by Fig. 11, and discontinued the fan of the same name previously manufactured. The new machine has a bipolar field magnet and a Gramme ring armature, somewhat similar in construction to the arrangement used hitherto. The field winding is in two sections, wound directly on the magnet core, which is, of course, previously insulated. The commutator is of the conventional drum type instead of the disc form previously used, and it is located in a much more accessible position than heretofore. The speed-controlling resistance is located beneath the fan in an open case, so that the breeze from the blades vastly enhances the ventilation. Fig. 12 illustrates the electrolier form of this fan.

The Dayton Company is continuing the excellent line of desk and bracket fan-motors and the "Original Dayton" and "Dayton Junior" ceiling fans previously manufactured. The desk fans are built in 12-inch and 16-inch sizes, with rigid mounting or swivel and trunnion. The bracket motors are built only with swivel and trunnion mounting. All are wound for either 110 or 220 volts direct current.

The Diehl Manufacturing Company, Elizabethport, N. J., has added to its line of desk and ceiling fans a new "No. 44" ceiling fan illustrated in Fig. 13. The motor has a bipolar field magnet of cast iron, cast in a single piece, and a slotted drum-wound armature. The armature slots are insulated with micanite troughs before the winding is put on. The coils are machine-wound directly into the slots. The casing of the motor is ornamental filagree work at the top and bottom, with a belt of sheet metal heavily japanned and striped in gilt. The Nos. 28 and 45 fans of previous years have been discontinued; the line is otherwise unchanged.

FIG. 11.—"DAYTON" DIRECT-CURRENT CEILING FAN MOTOR.

The well-known line of alternating-current fan-motors built by the Emerson Electric Manufacturing Company, St. Louis, Mo., has been augmented by a "residence-type" induction-type machine of the same general construction as the "Trojan" line which was brought out last year. Fig. 14 shows the general appearance of the new machine. The field magnet, or stator, has six poles, and the speeds of the machine are thereby reduced to 1100 r.p.m. and 900 r.p.m., the lower speed being obtained by means of a switch and reactance coil. The motor is intended for 60 cycles only, and is made only in the 12-inch size. The power required is 75 watts at full speed and 55 watts at the lower speed. Swivel and trunnion mounting is employed, and in either the pedestal or the bracket form. The Emerson Company continues the manufacture of all of its excellent Emerson and Trojan desk and ceiling fans, which were described and illustrated in last year's article. These, it may be remembered, comprise 12-inch and 16-inch desk and bracket fans for 60 or 133 cycles, and the standard voltages, with swivel and trunnion mounting; two-blade and four-blade ceiling fans of the usual speeds for 60-cycle circuits, in both the standard Emerson and Trojan types, and a high-speed five-blade Emerson ceiling fan for 133 or 60 cycles. The Emerson ventilating fan outfits for both direct and alternating current are also continued this year.

FIG. 12.—DAYTON CEILING FAN MOTOR.

FIG. 13.—DIEHL CEILING FAN MOTOR.

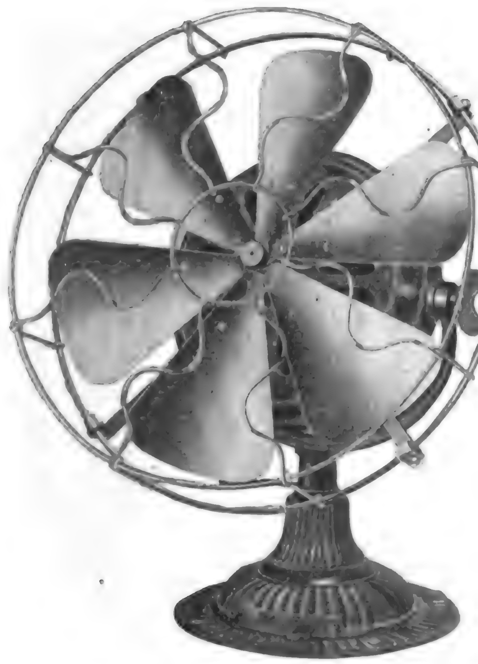

FIG. 14.—EMERSON ALTERNATING-CURRENT RESIDENCE-TYPE INDUCTION FAN MOTOR.

Fidelity Electric Company, Lancaster, Pa., has brought out a new alternating-current fan-motor this year. It is a simple series-wound commutator motor, with a bipolar field-magnet (laminated, of course), and a slotted drum armature. The commutator is insulated with mica throughout, and the insulation in other parts of the machine is of correspondingly high quality. The case is of aluminum, and the complete machine, with its 8-inch fan, weighs only 28 ounces. The motor is mounted on a combination pedestal convertible into a bracket, as shown in Figs. 15 and 16, or arranged for suspension from a lamp socket, as shown in Fig. 17. It runs at 1800 r.p.m. and requires 15 watts at that speed. The company also continues the entire line of direct-current desk, bracket and ceiling fans heretofore manufactured. These were described in our articles of March, 1903 and 1904.

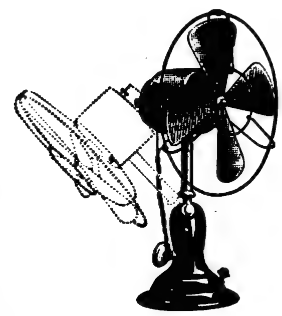

FIG. 15.—FIDELITY DESK FAN MOTOR.

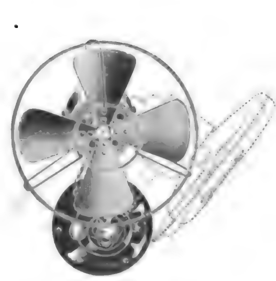

FIG. 16.—FIDELITY BRACKET FAN MOTOR.

Fort Wayne Electric Works, Ft. Wayne, Ind., has not added any new motors to its very complete line of direct and alternating-current machines, but the motors have undergone considerable improvement in constructural details, and a 12-inch size, with bracket mounting, has been added. The standard line has 8-inch fans. The conductors leading down the suspension cord of the hanging type of fan have been improved so as to eliminate the possibility of chafing and breaking. The bearings have been changed so that they are self-aligning. The automatic felt oilers have been retained. The brushes are carbon pencils of square cross-section fed in cartridge holders by helical springs, as indicated in Fig. 18, but they differ from the usual type in having a flat spring on the side of each brush which presses it into intimate and positive contact with the holder, and also prevents noisy operation due to chattering. As heretofore, the "Wood" fan-motors are built for 115 volts direct current, and for 52 or 100-115 volts alternating current, either 60 or 140 cycles. The three mountings—desk, bracket and suspension—are as before. The telephone booth fan-motor described last year is also built this season.

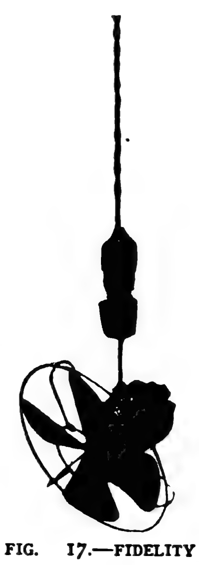

FIG. 17.—FIDELITY SUSPENSION FAN MOTOR.

FIG. 18.—FT. WAYNE BRUSH HOLDER.

The Peerless Electric Company, Warren, Ohio, has made no changes in the internal construction of its well-known line of desk, bracket and ceiling fan-motors. The frames of the desk and bracket types, however, have been much improved in appearance. A

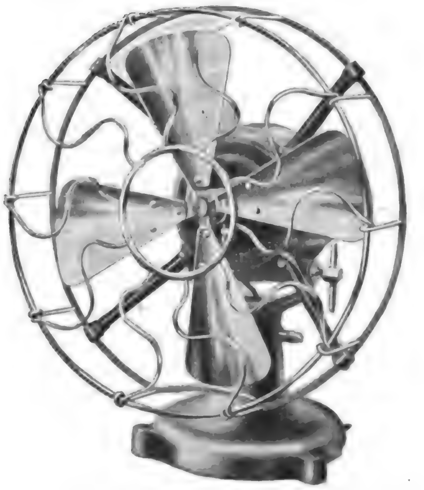

FIG. 19.—PEERLESS DESK FAN.

handsome smooth-finished pedestal and motor casing have been substituted for the fluted and ribbed exteriors previously used, and the difference will be appreciated by comparing Figs. 19 and 21 with Figs 53 and 54 of last year's article. A rigidly-mounted desk fan has been added also. The details of construction are the same as last year, with the exception of the mounting. These machines are built for the usual voltages, and the Peerless ceiling and column fans for standard direct-current voltages are again manufactured. A new oscillating fan-motor has been perfected for this season's market, but unfortunately the details of construction are not yet available. We hope to describe this machine next month.

Shedd Electric Company, New York, continues the manufacture of its "Comfort" oscillating fan-motor this year, and has brought out a new "Universal" machine, which is illustrated by Figs. 22 and 23. Fig.

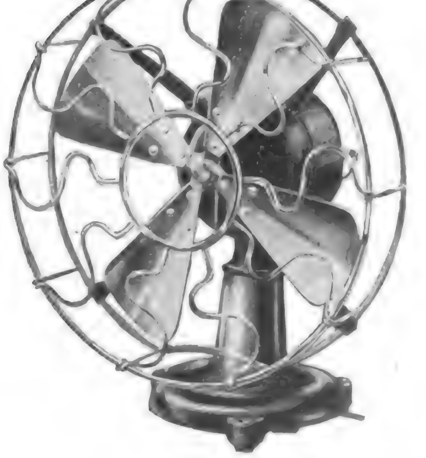

FIG. 20.—PEERLESS RIGID-PEDESTAL DESK FAN.

24 is a view of the frame with the armature and one end-cap removed. The field-magnet is cast in a single piece with holes, at each end of its axis, bored out to the same diameter as the pole-faces. The magnet coils are form-wound and heavily insulated before being put in place; the armature is of the usual slotted drum type. The brushes are square carbon pencils, and are fed to the commutator in box holders by helical springs. The holders are so con-

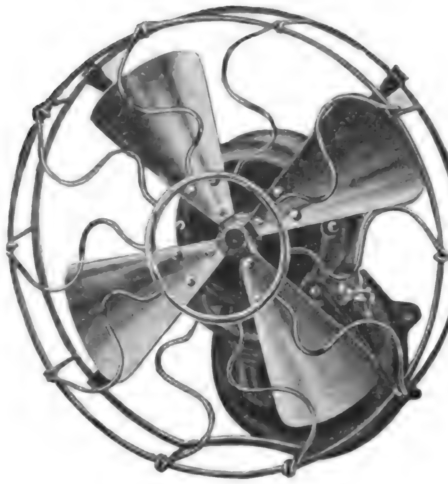

FIG. 21.—PEERLESS BRACKET FAN.

structed that a brush may be removed by merely pushing it back far enough to clear two ribs which normally hold it in the box. The machine is changed from pedestal to bracket form by loosening a set screw in the top of the pedestal, adjusting the motor body to the desired position and resetting the screw. The bearings are in the end-caps, and are lubricated either by underfeed wick oilers or by the top-feed grease cups shown in the engravings. The machine runs at 1000, 1400 or 1700 r.p.m., being equipped with a rheostat and switch to regulate the speed. It is built for the standard direct-current voltages in both 12-inch

FIG. 24.—SHEDD FRAME AND ARMATURE.

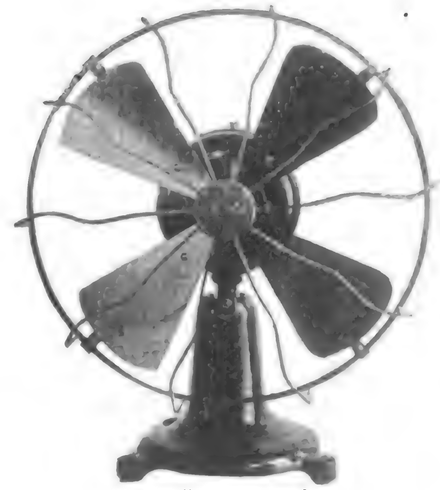

FIG. 22.—SHEDD "UNIVERSAL" FAN MOTOR.

and 16-inch sizes, and for 60-cycle alternating current of standard voltage in the 12-inch size only.

The Westinghouse Electric & Manufacturing Company has brought out a complete new line of desk, bracket and ceiling fan-motors for direct and alternating currents, the constructional details of which are not yet available. Figs. 25 and 26 illustrate the desk and bracket forms and show that the mounting is the swivel and trunnion type. The desk mounting is changed to bracket form by the insertion of a small adapter between the top of the pedestal and the motor

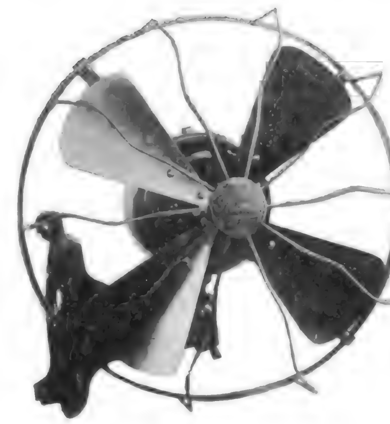

FIG. 23.—SHEDD "UNIVERSAL" FAN MOTOR.

body. The switch handle projects through a slot in the pedestal base as shown in Fig. 26. The direct-current machines run at 1000, 1300 and 1650 r.p.m. the 12-inch alternating-current fans run at 1300 and 1650 r.p.m., and the 16-inch fans at 1650 r.p.m. The fan blades are slightly dished, this form being claimed to give better air displacement than the flat type.

Jones Fan & Motor Company, New York, has brought out a new battery fan, which is illustrated by Figs. 27 and 28, and is known as the Perfection fan-motor. The field-magnet is of the familiar single-coil bipolar type, and the armature is of the polar type with three poles and coils; the armature core is laminated and the winding is protected at the ends by circular shields of insulating material, as indicated in the rear view, Fig. 28. The commutator is round and turned true with the shaft; the brushes are of copper gauze. The bearings are well lubricated by oil cups—not provided with

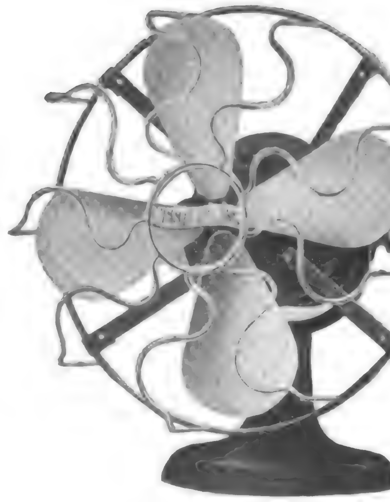

FIG. 25.—WESTINGHOUSE DESK FAN MOTOR.

mere holes through which a drop or two of oil can be administered. The fan is 10 inches in diameter, and the motor drives it at 950 r.p.m. when supplied with current at 6 volts, and takes 0.8 ampere at that speed.

Kendrick & Davis, Lebanon, N. H., have also brought out a new battery fan-motor

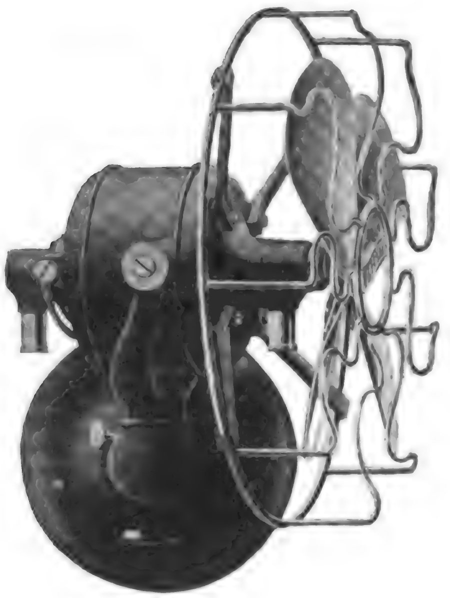

FIG. 26.—WESTINGHOUSE BRACKET FAN MOTOR.

this season. Fig. 29 shows the complete machine and Fig. 30 the motor dismantled.

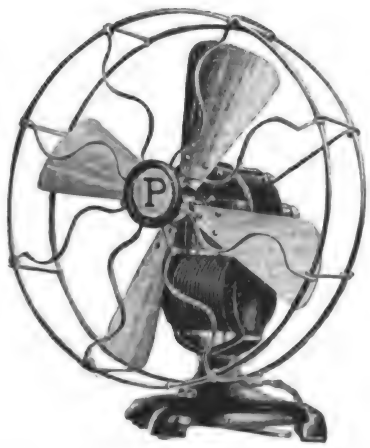

FIG. 27.—PERFECTION BATTERY FAN MOTOR.

The field magnet is cast in one piece and provided with form-wound and hand-insu-

FIG. 28.—PERFECTION BATTERY FAN MOTOR.

lated coils. The armature is of laminated construction with six polar projections and coils. The commutator is of the usual drum form, insulated with hard fibre. The brushes are carbon pencils fed to the commutator in boxes mounted in lugs which are cast on one of the end caps, as shown in Fig. 29.

FIG. 29.—KENDRICK & DAVIS' BATTERY FAN MOTOR.

The mounting of the machine is obvious from the engravings. It has a 6-inch fan, and runs at 2400 r.p.m. when supplied with current at 7 volts. The current taken at this e.m.f. is ½ ampere.

American Blower Company, Detroit, Mich., has improved its method of mounting this season. Fig. 31 shows the new

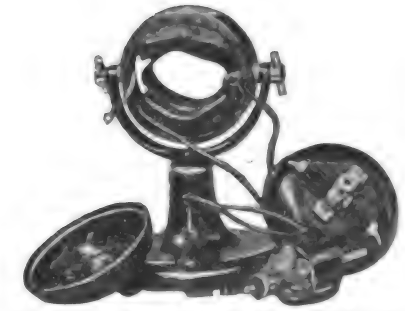

FIG. 30.—KENDRICK & DAVIS' MOTOR DISASSEMBLED.

arrangement, in which the motor is set on a substantial cast-iron foundation, and the

FIG. 31.—AMERICAN BLOWER OUTFIT.

fan casing is attached to the motor frame. Last year the fan casing was mounted on a base and the motor hung from it by braces. The motor used this season is the well-known Westinghouse Type S machine, for standard direct-current voltages. Any standard motor, however, may be used.

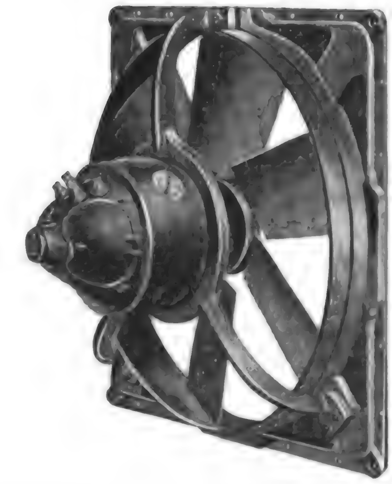

FIG. 32.—TRIUMPH FLAT-BLADE EXHAUST FAN AND MOTOR.

Fig. 32 illustrates the Triumph ventilating outfit built by the Specialty Manufacturing Company, Indianapolis, Ind. The motor is

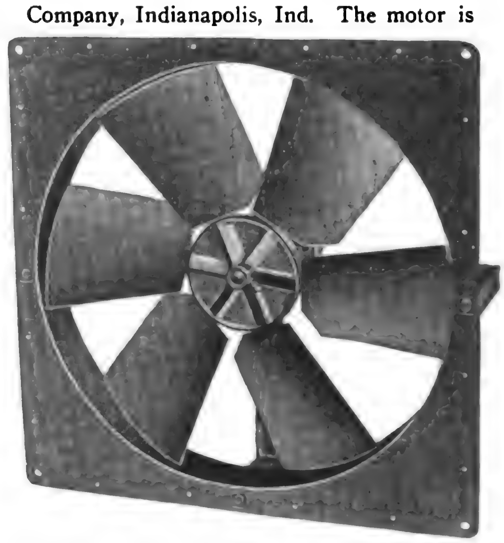

FIG. 33.—EXHAUST SIDE OF TRIUMPH FAN.

bolted to a three-armed spider, which is in turn bolted to a substantial cast-iron wall plate. The fan is mounted directly on the shaft by the motor. No outboard bearing

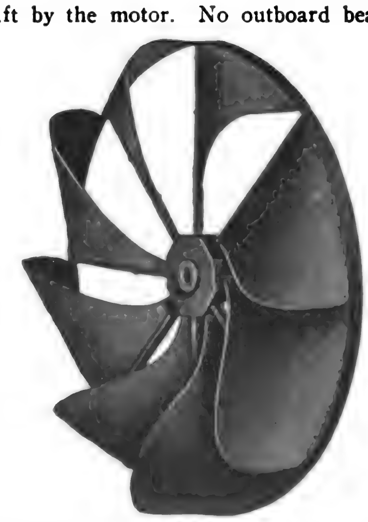

FIG. 34.—TRIUMPH PROPELLER BLADE FAN.

is needed. The method of mounting the fan blades on the hub is shown in Fig. 33, which is a view of the exhaust side of the fan. This type is built for the standard direct-current voltages in sizes of 24, 30 and

36-inch fans, the maximum speeds of which are 900, 700 and 650 r.p.m., respectively. The company also builds the propeller type of fan shown in Fig. 34, with the same style of mounting. The sizes and speeds of this type are 24 inches, 800 r.p.m.; 30 inches, 650 r.p.m. and 36 inches, 600 r.p.m. Speed regulators giving eight speeds, ranging from one-half to full speed, are furnished with both types The outfit comprising a Tri-

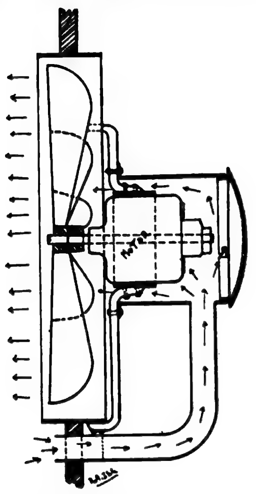

FIG. 35.—VERTICAL SECTION OF ELECTRIC VENTILATING COMPANY'S HOOD.

umph fan and a detachable motor, described two years ago in our annual fan-motor article, is continued as heretofore.

Electric Ventilating Company, Chicago, has brought out an attachment for motor-driven ventilating fans, which is designed to protect the motor from deleterious fumes, gases, etc., and also to provide artificial ventilation of the machine by means of a current of cool air taken from the outside atmosphere. The device consists of a hood completely surrounding the motor and covering one end of it, and a pipe leading from the side of this hood to the outer air, as shown in Fig. 36. The end of the hood toward the fan is open and the fan draws cool air through the pipe and hood, thereby reducing the temperature of the motor by convection. The main body of contaminated air drawn out of the room by the fan does not come into contact with the motor, the hood being interposed. Fig. 35 is a vertical section showing the motor within the hood. When the air or vapors discharged by the

FIG. 36.—ELECTRIC VENTILATING COMPANY'S OUTFIT.

fan are lighter than the outside air, as is usually true, the pipe leading from outside to the hood is located as shown in Fig. 36, so that it will not draw back any of the main discharge. When the main discharge is heavier than pure air, however, the hood pipe is arranged at the top, or exactly opposite to the arrangement shown in Fig. 36.

The following manufacturers are continuing their respective lines, which were fully described last year, no need for changes having developed. The Robbins & Myers Company, however, has added to its line of Standard machines a new Universal fan-motor which will be described next month, the engravings illustrating the constructional details being delayed by the engravers until too late to publish the description in the present article.

The D. L. Bates & Brother Company, Dayton, Ohio.—Direct-current desk, bracket, ceiling and column fans for the standard voltages.

Century Electric Company, St. Louis, Mo. —Alternating-current ceiling fan-motors for the usual frequencies and voltages.

The Colonial Fan & Motor Company, Ravenna, Ohio.—Direct-current desk and ceiling fan-motors for standard voltages.

General Incandescent Arc Light Company, New York.—Paragon desk and bracket fan-motors for standard direct-current voltages.

The Jandus Electric Company, Cleveland, Ohio.—Desk and bracket fan machines for direct and alternating current; also the "Gyrofan" mounting for either ceiling suspension or floor column.

The Pennsylvania Electric Company, Marietta, Pa.—Crescent desk, bracket and ceiling fans for direct-current circuits.

The Robbins & Myers Company, Springfield, Ohio.—Standard desk, bracket and ceiling fan-motors for the standard direct-current voltages.

Sprague Electric Company, New York.—Lundell desk and bracket machines for the regular direct-current voltages and alternating-current voltages and frequencies; also the ceiling fan described in 1903.

Sterling Electric Motor Company, Dayton, Ohio.—Ceiling fans for the usual direct-current voltages.

Western Electric Company, New York and Chicago.—Desk, bracket and ceiling fans for the regular direct-current voltages, as described in full detail last year.

Edison Manufacturing Company, Orange, N. J.—Battery fan motors and batteries.

Knapp Electric & Novelty Company, New York.—Battery fan motors and batteries.

B. F. Sturevant Company, Hyde Park, Mass.—Motor-driven ventilating fans and blowers of both "paddle-wheel" and propeller types, with direct-current motors of different types, according to the class of service, and wound for the usual voltages.

Massachusetts Fan Company, Waltham, Mass.—Ventilating fans adapted for motor drive and designed for the usual classes of service.

The Barney Ventilating Fan Works, Boston, Mass.—Barney "Compound" ventilating wheel, adapted for direct motor drive.

GERMAN CENTRAL STATION STATISTICS.

The *Elektrotechnische Zeitschrift* devotes considerable space to the yearly statistics of German central stations comprising a vast amount of information current up to April, 1904. While the present number of central stations in Germany is over 1100, the statistics cover only 1028 plants, and only those are included which sell current to consumers or supply public lighting. Isolated plants are not included. There were 51 plants having a capacity of more than 2000 kilowatts in 1904. The three largest are in Berlin, and their respective output is 85,136, 30,000 and 25,895 kilowatts. The total capacity of the 51 stations of more than 2000 kilowatts is 296,693 kilowatts, these stations being in 33 cities. The development of central stations and their connections in Germany in general is shown in the following table:

	1894.	1900.	1904.
No. of stations ...	148	652	1,028
No. 50 watt incan. lamps connected.	493,801	2,623,893	5,687,382
No. of 10 amp. arc lamps connected.	12,357	50,070	110,856
H.P. of motors (not incl. trac.)	5,635	106,368	263,036

In recent years several plants have been erected which supply current to a number of cities and towns in a district; thus the Bruehl central station supplies current for lighting and power to 66 towns at a distance of from 9 to 12 miles from the station. On the other hand, there are some small plants which supply current for power purposes to houses for the support of house industries. A typical example is the Anrath plant near Crefeld. All the motors connected to the mains are in this case between ¼ and ½ horse-power, and are used in the silk industry. In recent years the use of power has enormously increased, as is shown in the following table of comparison between the kilowatts used for lighting and for power, traction motors not being included in the latter case:

	Kw. for lighting.	Kw. for power.	No. of motors.
1885	250	.....	.....
1890	3,899	112	28
1895	10,752	2,252	663
1900	21,122	22,037	5,764
1904	36,195	44,448	12,933

There is only one plant in Germany which buys energy in bulk from a larger works and sells it in retail to consumers; this is the Spandau station, which gets the current from one of the Berlin works. Statistical data concerning the systems used are given in a following table:

	No. of works.	Kw. of machines.	Kw. of batteries.	Total capacity in kw.
Direct current with storage batteries..	803	175,263	69,957	245,220
Direct current without storage batteries	40	2,346	.....	2,346
Alternating cur., single ph. and two ph.	41	37,317	400	37,717
Three phase current	63	69,054	1,532	70,586
Monocyclic system	2	1,030	152	1,182
Mixed three phase and direct current .	64	141,330	23,169	164,499
Mixed alternating and direct current ..	15	8,542	855	9,397

Concerning the power used the statistics show that 570 plants with 341,248 kilowatts use steam power, 109 plants with 14,547 kilowatts use water power, 208 plants with 60,672 kilowatts use both steam and water power, and 94 plants of 10,050 kilowatts use gas power.

SOUTHERN MACHINERY DEALERS' CONVENTION.

The executive committee of the Southern Supply & Machinery Dealers' Association held a meeting at New Orleans on February 16 and 17 and made arrangements for the annual convention of the association, which is to take place April 25 to 28, at the De Soto Hotel, Savannah, Ga. The executive committee has appointed Mr. Denny, of the Georgia Supply Company, Savannah, Ga., chairman of the entertainment committee, and Mr. Dissosway, of the Cotton States Belting & Supply Company, Atlanta, Ga., chairman of the transportation committee. Favorable rates have been made with the De Soto Hotel and the programme that has been adopted is expected to be extremely interesting to every manufacturer and dealer in the United States.

The executive committee extends an invitation to all supply dealers, and also to the representatives of the different manufacturers with whom the supply dealers do business, to attend the convention.

The entertainment committee has made arrangements that insure every one present a fine time. Savannah is one of the most attractive cities of the South, and at the time of the year chosen for the meeting, the city will be seen at its best.

Some Recent Electrical Patents

Combined Circuit-Breaker and Motor-Starting Rheostat.—The now familiar automatic-return motor-starting rheostat was developed, of course, in order to guard against the possibility of connecting a standing motor to a supply circuit with the starting resistance partly or entirely cut out. In order to provide the same precaution in another way, the combination starting box and circuit-breaker, illustrated diagrammatically by Fig. 1, has been devised and patented by Robert H. Read, of Schenectady, N. Y. The circuit-breaker consists of a pivoted arm, 4, carrying an insulated contact, 3, which bridges the stationary contacts, 2, when the circuit-breaker is closed, as shown in the diagram. The circuit-breaker arm is held in the closed position by means of the latch, 6, which is pivoted near the potential magnet, 7, and held in the locking position by that magnet. The handle, 9, of the circuit-breaker is not rigidly connected to the circuit-breaker arm, 4; it is mounted on the same pivot, 5, and provided with a dental clutch, 10, as shown in the horizontal view at the bottom of the diagram. A forked arm, 11, under the influence of a spring not shown, normally holds the handle, 9, unclutched from the hub of the circuit-breaker arm, 4. This forked arm is pivoted at 20, and an integral lug at right angles to it is engaged by a bifurcated arm, 12, mounted on the same hub with the finger, 19. The arm, 14, of the starting rheostat is provided with a lug, 18, which engages with the finger, 19, when the resistance is all cut into the circuit.

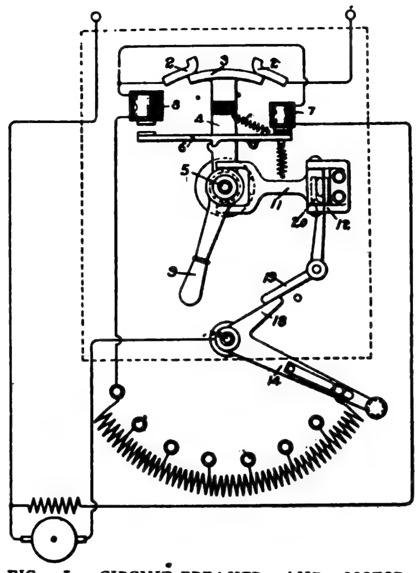

FIG. 1.—CIRCUIT-BREAKER AND MOTOR-STARTER.

Though the description is somewhat complex, the operation is very simple. When the arm, 14, is moved around to the left to cut out the resistance and start the motor, the finger, 19, is released and the spring controlling the arm, 11, throws out the clutch on the hub of the lever, 9, so that that lever cannot actuate the arm, 4, of the circuit-breaker. If the current supply should fail, the potential magnet, 7, will release the latch, 6, allowing the circuit-breaker to be opened by its spring; similarly, if the current taken by the motor should be excessive, the current magnet, 8, will lift the latch, 6, against the restraining influence of the magnet, 7, and thus release the circuit-breaker. As the arm, 11, holds the clutch on the hub of the lever, 9, disengaged, the circuit-breaker cannot be restored by means of the lever, 9. If, however, the lever, 14, is swung back to the zero position, as shown in the diagram, its engagement with the finger, 19, sets the dental clutch, 10, on the hub of the lever, 11, and enables that lever to reset the circuit-breaker. Patent 779,182.

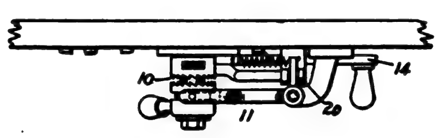

FIG. 2.

Commutator Brush Holder.—One of the disadvantages of the familiar box-type brush holder is that unless a spring is used which takes up a great deal of space, the pressure of the brush against the commutator becomes rapidly lessened as the brush wears away. In order to overcome this, Mr. Ernst Woehr, of Wilkinsburg, Pa., has devised the arrangement shown in Fig. 3. The brush is pressed toward the commutator by the toggle links 6 and 8, pivoted to the framework at 5 and having the knuckle at 7. A spiral spring, 9, pulls on the link, 6,

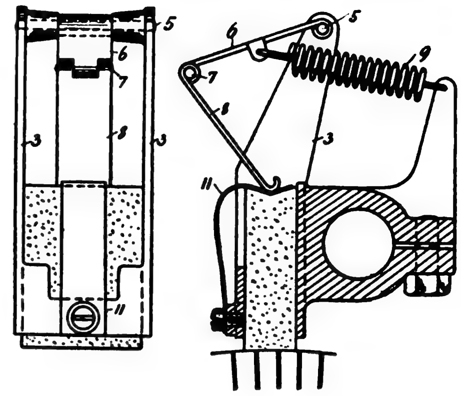

FIG. 3.—COMMUTATOR BRUSH-HOLDER.

and forces the brush downward; as it wears away and the lower end of the link, 8, follows it down, the toggle angle becomes

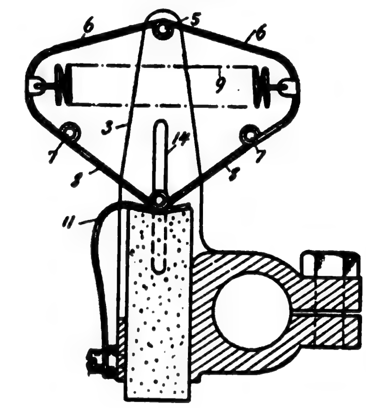

FIG. 4.—COMMUTATOR BRUSH-HOLDER.

greater and greater, increasing the leverage of the spring, 9, over the toggle sufficiently to compensate for the decreased pull of the spring as the spirals contract. A thin con-

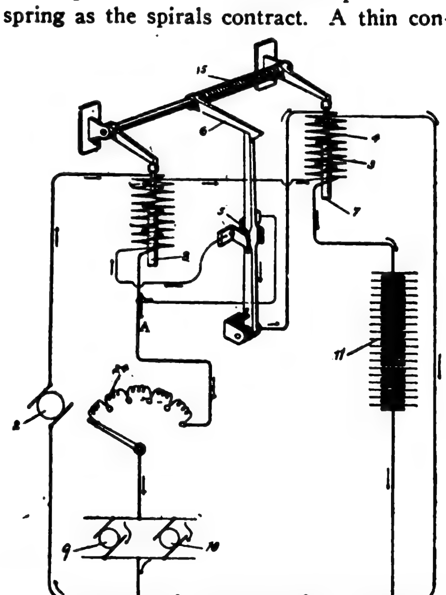

FIG. 5.—SCOTT'S DOUBLE-DUTY CIRCUIT-BREAKER.

ducting leaf, 11, is secured at one end to the brush box, and its other end is pressed against the upper end of the brush by the toggle link, 8. Fig. 4 shows a modification in which two toggles are used, the two being drawn together by a spring attached to both.

The lower ends of the links, 8, 8, are pivotally connected and the pivot pin extended through a guide slot, 14, to keep the ends on the middle of the brush-end; the latter is shaped to facilitate this in both cases. Patent No. 777,709.

Double Duty Circuit Breaker.—Ordinary overload circuit-breakers for the protection of electrical apparatus are, of course, perfectly familiar, and reverse-current circuit-breakers for preventing current flow in the wrong direction are also well known; Fig. 5 illustrates diagrammatically an ingenious combination of these two classes of apparatus which has been patented by Mr. William M. Scott, of Philadelphia. The circuit-breaker contacts are represented conventionally by the lever and jaws, 5. The lever is held in by the latch, 6, under the influence of the spiral spring, 15, and may be released by either of the solenoid plungers, 7 and 8. The two solenoids are provided with differential windings, the potential windings of the two being connected in series through the circuit-breaker and across the supply circuit, *A-B*, to which a storage battery, 11, is also connected. The series winding of one solenoid is in series with the motor circuit, *A-B*, and the series winding of the other solenoid is in series with the storage battery. The potential winding of the solenoid, 7, and the adjustment of its plunger are such that under normal conditions the potential winding is almost strong enough to lift the plunger. Consequently, the amount of normal current through the series winding must be very great in order to overcome the potential winding and trip the circuit-breaker. The motors, 9 and 10, and the storage battery, 11, are supposed to be mounted together with the circuit-breaker on a railway car, such as a mining locomotive, and the chief function of the circuit-breaker is to guard against excessive current delivery to or from the storage battery. For example, if the generator, 12, should fail for any reason, the battery, 11, would discharge back into the line, if the line circuit were closed, and it would discharge through the motors in any event. So long as the current taken by the motors remained normal, the cumulative effect of the potential winding and the series winding of the solenoid, 7, would be insufficient to raise the plunger, but if excessive current should flow from the battery to the motors, the plunger, 7, would be lifted and the circuit opened. Again, if upon the failure of the generator, 12, the line circuit remained closed, the storage battery would send a reverse current through the series winding of the solenoid, 8, and the cumulative effect of the series and potential windings would lift the plunger and open the circuit-breaker. Patent 779,376.

CENTRAL STATION ENGINEERS.

V.

Louis A. Ferguson.

Louis A. Ferguson was born in Dorchester, Mass., August 19, 1867. He was educated in the Boston public schools, graduating from the Dorchester high school in 1884. He then entered the Massachusetts Institute of Technology, and was graduated from that institution in 1888 with the degree of Bachelor of Science in Electrical Engineering. His thesis work consisted of original experiments to determine the "Law of Relation between Candle-power and Current, Voltage and Energy Consumed in Incandescent Lamps." At about the time that Mr. Ferguson was completing his studies at the Massachusetts Institute of Technology, the Chicago Edison Company began to develop its policy of expansion and the officials of the company were looking for competent engineering talent to carry out their plans. Mr. Ferguson, whose college work had attracted considerable attention, was offered a position in the company's underground department shortly after his graduation, which he accepted. His advancement thereafter was steady and rapid. In 1889 he was assistant electrical engineer of the construction department, and in 1890 he was appointed to the position of electrical engineer. His experience up to this point had been wholly on the engineering and operating side of the business, but the marked ability with which he handled such commercial work as came within his province attracted the attention of the management, and in 1893 his duties were enlarged to include the entire supervision of the company's contract business in addition to his engineering work. Mr. Ferguson was remarkably successful in this new field, particularly in the negotiation of valuable long-term contracts with some of Chicago's largest mercantile establishments, and on June 1, 1897, President Insull appointed him general superintendent of the company, in charge of the operating and electrical engineering departments, as well as the central station and isolated plant business. A year later Mr. Ferguson was also appointed general superintendent of the Commonwealth Electric Company.

LOUIS A. FERGUSON.

Mr. Ferguson's wide experience during his connection with the Chicago Edison Company has made him a recognized authority in this country on central station practice, and during the last fifteen years he has contributed a considerable number of papers to various associations, scientific societies and colleges. In 1895 he was on the staff of lecturers at the University of Wisconsin, and delivered a lecture on "Electrical Engineering in Modern Central Stations," which was subsequently published by the university. In 1896 Mr. Ferguson read a paper at the convention of the National Electric Light Association, held in New York City, May 5, 1896, on "The Commercial Value of Acetylene Gas as an Illuminant," giving the results of his experiments made with Messrs. Wilson and Knapp at Spray, North Carolina, in 1895, in the production of calcium carbide and acetylene gas. This paper was published by order of the National Association, and is considered one of the ablest contributions that have been published on this subject, being widely reviewed at the time by the technical press. Another important contribution was his work in conjunction with Dr. Louis Bell and James I. Ayer upon the preparation of a suitable specification for a standard incandescent lamp and the determination of a proper method for the commercial application of this standard. The result of this work was presented in an elaborate report entitled "Standard Candle-power of Incandescent Lamps," which was submitted to the National Electric Light Association at Niagara Falls, January 10, 1897. The subjects of other papers read before technical societies or published in the technical press are as follows: "The Economy in Distribution of Electric Energy," "Development of a Central Lighting System," "General Distribution from Central Stations by Direct Current," "The Methods of Charging for Electrical Energy," "Central Station Advancement," "Progress of Central Stations," "Storage Batteries for Small Stations," "Distribution of Electrical Energy in Large Cities," "Central Station Operation," and "Rates."

On July 9, 1902, the directors of the Chicago Edison Company and the Common-

wealth Electric Company recognized the importance of Mr. Ferguson's services by electing him second vice-president of both companies, which position he holds at the present time.

Mr. Ferguson was elected president of the Association of Edison Illuminating Companies for the year 1901-2, and re-elected to the same position for the year 1902-3. He was also elected president of the National Electric Light Association for the year 1902-3, and is now a member of the executive committees of both associations. He is also a member of the board of managers of the American Institute of Electrical Engineers, and at the International Congress, held in St. Louis last summer, he contributed a paper entitled "Underground Electrical Construction."

Mr. Ferguson is married, and resides in Evanston, one of the most beautiful suburbs of Chicago. While not a club man in the ordinary acceptation of the term, he belongs to a large number of clubs, including the Union League, Merchants, Chicago Athletic, Evanston Country Club and the Onwentsia, Glenview and Edgewater golf clubs.

Mr. Ferguson is credited with being the first engineer in this country to suggest a central station system generating three-phase alternating current with transmission lines to sub-stations, operating rotaries, converting from alternating to direct current for general distribution.

NOTES.

Results of a Year.—The International Committee of Young Men's Christian Associations has just issued a handsome booklet showing the progress of the Y. M. C. A. Railroad Department for the past year. The development of this branch in many respects has been phenomenal.

Directness of Exhaust-Steam Connections especially where high vacua are desired, is generally provided for in power-station design, but the relative effect of interposed valves is often greater than supposed. In a recent test at the Battersea electric central station, London, it was found that of a drop of vacuum from engine exhaust to condenser of 1½ in. of mercury, 0.8 in. was due to a non-return valve.

Evening Lectures at the Brooklyn Polytechnic Institute.—The first of a series of eight two-hour lectures on electrical power transmission was delivered by Dr. F. A. C. Perrine on February 9 at the Brooklyn Institute. This lecture had for its subject "The Economics of Transmission Problems.". The topics discussed by the speaker were: Adequacy of Supply, Extent of Market, Character of Market, Competitive Fuels, Transportation, Distribution, and the Importance of Controlling Property. On February 14 Mr. W. S. Barstow delivered his sixth lecture on "Central Station Practice," in which he discussed distributing systems. Mr. Barstow went very thoroughly into the details of the construction of distributing systems, such as ducts, cables, manholes, etc.

Size and Lift of Stop Valves.— It is the almost universal practice to make the diameter of the stop valve on a boiler the same as the diameter of the supply steam pipe to prevent throttling and to make the maximum lift equal to one-fourth of the diameter, in order that the cylindrical area of escape may be equal to the cross-section or bore of the pipe. Experience shows, however, these are extreme views of a valve's requirements as a local contraction in a pipe causes very little interference with the flow of steam, and in practice it is seldom a valve is open more than one-third to one-half the extent which by calculation would appear to be necessary.—*Exchange.*

Central Station Statistics.—In a very able paper on "Central Station Design," read recently by Mr. I. E. Moultrop before the American Institute of Electrical Engineers, the author stated that there are now 3738 electric power stations, the total cost of which was, in round numbers, $500,000,000. The income from these stations from lighting and power service aggregates $90,000,000 per annum. The aggregate power developed by prime-movers in central station work is 1,300,000 horse-power, of which 438,000 horse-power is hydraulic. There are in use 419,000 arc lamps and 19,000,000 incandescent lamps. In the discussion of the paper, President Lieb gave the interesting information that extensive observations taken in one of the principal large New York central station plants had shown that of the total generating capacity 10 per cent was used only twenty-five hours per annum, and that twenty-five hours was contained in a single month; 25 per cent of the plant was used seventy-five hours per year, all within the scope of two months, and 50 per cent was used only 500 hours per year, within the limits of seven months.

Steam Pipe Covering Tests.— Tests of a steam pipe covering of asbestos 1.53 in. thick and made in flat sections 3 by 2 ft. in size, wrapped around the pipe and laced with copper wire, were reported recently in *The Electrician*, of London, from results obtained at the National Physical Laboratory. The covering averaged 2 lb. weight per running foot or 1.7 lb. per square foot of the external surface of the 4-in. pipe used in the tests. The trials were conducted in a usual manner with a 14.34 ft. length of the pipe inclined 6 in. in this distance. The radiating surface of the pipe was 16.85 sq. ft. With a steam temperature of 392.7 degs. and air temperature of 67.7 degs., the condensation of the bare pipe was 1.66 lb. steam per square foot per hour, and the heat loss 4.27 b.t.u. per square foot per hour per degree difference in temperature. With a steam temperature of 393.4 degs. and air temperature of 64 degs., the condensation with the covered pipe was 0.212 lb. per square foot per hour, or 0.54 b.t.u. per square foot per hour per degree. It was calculated that the losses with steam pressures of 190, 200, 210 and 220 lb. by gauge were, for the covered pipe, 168.4, 170.6, 172.7 and 174.6 b.t.u., respectively, per hour per square foot, and, for the bare pipe, 1339, 1357, 1373 and 1389 b.t.u., respectively.

Pacific Coast Water Powers for Railroad Work.—Mr. Robert McF. Doble, of San Francisco, recently read a most interesting paper before the Pacific Coast Railway Club of that city, on "The Use of Pacific Coast Water Powers in the Electrical Operation of Railroads," in which he pointed out that although only a small portion of the available water powers on the Pacific Coast has been developed, the present conditions would appear to make the operation by electricity of some of the railroads in that section profitable. The author pointed out that the capacity of the steam locomotive must necessarily be that required to exert its maximum effort, even though the duration of maximum pull be extremely short, whereas the average load of a power station supplying a railroad line will be much less than the total maximum capacity of the electric locomotives supplied by it. This would materially reduce the cost of operating, especially under the conditions found on the Pacific Coast, where several power plants can feed into a single network. Reference was also made to the reduction in cost and maintenance of the roadbed of the electrically-equipped railroad as compared with one using steam locomotives, the possible increase in the capacity of existing railroads, and the ease of operation and maintenance.

The Search for Men.—In an interesting address on this subject recently delivered by Mr. H. J. Hapgood at a local branch of the Young Men's Christian Association, the speaker stated that one of the greatest evils among business customs is the indiscriminate giving of letters of recommendation by employers. He said that the best testimonial he ever saw contained exactly fifteen words, reading as follows: "Worked for us four years at $50 a week; wish we could have him back." He also pointed out the injustice of the assumption by employers that a man over forty years old is ineligible for responsible positions, and predicted that within a few years large employers would abandon the present prejudice in favor of men between thirty and thirty-five years of age, which is now working serious injustice to older men. He stated that a study of the employment problem had led him to believe that the demand for capable men in almost every line of skilled employment, except artisans, is far in excess of the supply. "High-salaried positions," he said, "are not vacant, but they are filled by men not big enough for them. Over 1000 men of the proper ability could secure positions in New York to-morrow at salaries of $5000 a year and over." It should be carefully noted that Mr. Hapgood, in all of his statements, prescribed men of the *requisite degree of ability*, not men who fancy themselves capable of filling any position.

ESTABLISHED 1889.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED

Electrical Industries.

Address all business communications to AMERICAN ELECTRICIAN, *114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, draft, express or postal money order, payable to McGraw Publishing Company.

Vol. XVII. MARCH, 1905 No. 3

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue, 18,000 copies are printed. The total number of copies printed so far this year is 56,000, or an average of 18,666 per issue.*

CONTENTS.

Motor-Driven Steam Plant Auxiliaries.

The proposition to drive all the steam plant auxiliaries of an electric lighting or power station by electric motors is a most attractive one on the surface, and we have always advocated this practice—under proper conditions. No rule is universally applicable without discrimination, excepting, of course, the few fundamental rules in the moral code. Motor-driven pumps, fans, etc., are immeasurably preferable to the steam-driven machines in all cases where there is available from other sources a sufficient supply of feed-water-heating steam which would otherwise be wasted. For the vast majority of cases it will be found safe to adopt the policy of using enough steam-driven apparatus to furnish all the exhaust steam needed under the most exacting conditions for heating the feed-water, and, if there remains any auxiliaries not provided for, to apply motor drive to those. Naturally, in following this policy, those auxiliaries which are worst adapted for motor drive should be put in the steam class first, arranging the list as far as possible, so that the last machines to be considered will be those best fitted for motor driving.

This is not all there is to the problem, however. It is not enough merely to put down the list of machinery and blindly follow the general policy outlined above. In many cases it may be found upon careful analysis that it would pay deliberately to use a non-condensing main engine in order that the auxiliaries may be motor-driven, the feed-water heat being obtained, of course, from the main engine exhaust. Where water is free and the character of the load not ordinarily favorable for condensing engines, it will nearly always be preferable to use a non-condensing compound engine and drive all of the auxiliaries by electric motors, excepting the exciter dynamos in a small station generating alternating current. These may always be profitably belted to the alternators or to the engines driving them. Even in a few cases where boiler feed-water had to be bought, it has been found economical to run non-condensing main engines in order to get the exhaust heat for the feed-water. Unless the engine exhaust is insufficient in such cases, motor-driven steam-plant auxiliaries throughout will always be found preferable if they are properly designed and installed.

The alleged inflexibility of control sometimes urged against motor drive for pumps and blowers exists only in the imagination of steam-drive partisans or in the practice of hopelessly incompetent builders. That there is the slightest difficulty in regulating the work of a motor-driven machine of the type named will not be conceded for a moment by any progressive engineer. Direct-current motors, of course, should invariably be used where speed regulation is needed—and it is indispensable in about 99.9 per cent of the cases. There is not a station in existence where direct current is not necessary, and it is a simple matter to provide a supply large enough to include pump and blower motors. Given such a supply, the engineer who could not provide an efficient, simple and easily-maintained variable-speed motor would deserve only the usual fruits of dire failure—not sympathy or extenuation. But it should never be forgotten that motor drive is not inherently an engineering panacea.

High-Tension Insulator Pins

The question of wooden *vs.* iron insulator pins for high-tension lines drew out considerable discussion at the Power Transmission section of the recent International Electrical Congress, even though the subject was not specifically mentioned on the program. The insulator and pin are so intimately related that any discussion of insulators must sooner or later bring up the question of pins. The evidence is not all in as yet on either side of this question. The leaning of most of the congress members seemed to be toward the use of wooden pins for ordinary transmission work, although it was admitted that steel towers and long conductor spans might be the practice of the future on the more important lines, and that with these would come the use of steel pins, with insulators electrically strong enough to permit of bringing ground potential clear up into the insulator, as is done when metal pins are used.

The arguments on wooden *vs.* iron pins take a peculiar turn sometimes. One man will argue that if the insulators are made good enough, they do not need any assistance from the pins as far as insulation is concerned. Another will follow up that argument by saying that if the insulators were so good that iron pins could be used, they would be good enough so that there would be no trouble from leakage and burning of wooden pins if wood were used; therefore, "why use iron"? There is apparently a good deal of truth in this argument, but as we said before, the evidence is not all in. There are apparently some contradictory things about the evidence thus

far presented. On the face of it, the fact that sufficient leakage can be obtained over a given insulator under given conditions to burn or disintegrate a wooden pin would seem to show that the use of iron pins would only transfer the trouble to another point, either where the pin enters the cross-arm or where the cross-arm is attached to the pole. On the other hand, one participant in the Congress discussion cited his experience to the effect that the substitution of iron for wooden pins under the same insulators in a certain district had resulted in an enormous reduction in the number of insulator break-downs, in locations where wooden pins would be destroyed in four to six months.

Just why iron pins should give satisfactory service under insulators which permitted enough leakage to rot out or burn wooden pins is difficult to explain on sound theoretical grounds. The experience of one pioneer company in very high voltages has shown that there may be enough leakage over cross-arms and poles so that the concentration of this leakage by the use of metal lag screws and braces may produce serious results in the way of burning at these points. In view of this, it is possible, although not absolutely proven, that the use of iron pins in high-tension insulators which will not give satisfactory service on wooden pins would cause a burning or rotting at the points where the pin enters the cross-arm or at the point where the cross-arm is attached to the pole.

As to whether or not there is a certain insulating value in that part of a wooden pin which is entirely protected by the insulator, there is no room for argument. Dry wood properly treated is a good insulator, and if the core of a glass or porcelain insulator is filled with the end of a dry wood pin rather than by a metal pin, the equivalent thickness of the insulator at that point is certainly increased a certain amount. There is apparently some disagreement among high-tension transmission experts as to the cause of the burning and disintegrating of pins. Some apparently think it due to leakage directly through the insulator, and others attribute it to leakage over the surface of the insulator. There is also a discrepancy in the use of the terms describing the nature of the phenomenon which causes pin burning. That the burning of wooden pins starts by the disintegration caused by a brush discharge seems generally accepted, but as to just where this brush discharge takes place in practice on a working insulator on a pole line doctors disagree, and we need more testimony based on experience and careful observation.

Machine-Tool Drive.

An interesting paper on the electric driving of machine-tools was read recently before the Engineers' Club, of Philadelphia, by Mr. E. L. Walker. The author brought out several important points, but made the curiously inconsistent statement that "the ideal condition would be to get constant torque which would necessitate a larger horse-power at the higher speeds; nevertheless, it is a step in the right direction to get even a constant horse-power at all speeds." As he had already pointed out in a preceding paragraph, all of the multi-voltage systems give constant torque at all voltages, and therefore at all speeds, excepting such gradations as are effected by field control; but this is not always satisfactory for the reason that most machine tools require the greatest power at the slowest speeds. Power being the product of torque and speed, it is obvious that the ideal condition for tools requiring maximum power at slow speeds is decidedly not that of constant torque, but that of torque varying inversely with the speed and at least in direct ratio. This result is obtained by means of field regulation alone, and this is characteristic of many motors now manufactured.

The author also appeared to advocate the use of a mechanical speed-changing arrangement comprising an appalling conglomeration of gears, clutches, etc., which he characterized as having "solved this problem very nicely," and stated that "A speed-changing mechanism properly designed to give speeds in the ratios of 1 to 2, 4 to 8, etc., in connection with a variable-speed motor with a range of 1 to 2, will give every speed between the lowest and highest range." He might have omitted the variable speed motor and substituted some of the finely-graded speed-changing devices; then his mechanical museum would have been complete. Less discriminating engineers, however, would probably be satisfied to labor along with a variable-speed motor having a maximum range of 6 to 1, together with the ordinary simple back-gears on the machine tool.

A feature not discussed in the paper is that of controller arrangement. A motor regulated by field variation has the advantage that the controller may be made much smaller than one of any other type. This makes it easier to arrange the controller for direct manipulation by the tool operator; in fact, in many cases, the controller may be mounted directly on the apron of a lathe carriage or some convenient part of another form of tool, which is rarely, if ever, feasible in the case of other types of controller. There is the attendant disadvantage, however that the motor starting-box must be separate from the speed-regulating controller, if an ordinary type of motor starter be used; the consequence would be that with frequent starting and stopping, mounting the speed-controller on the machine tool would not be an appreciable improvement over a combined motor starter and speed regulator with the usual mechanical connections. But there would be a conspicuous advantage in using some one of the several good motor-starters controllable from a distance, together with a field-control rheostat, the latter being mounted within easy reach of the machinist and including in its construction a small switch, actuated by the speed-regulating handle, for cutting in and out the motor starter. The latter would be mounted preferably, but not necessarily, on the frame of the motor.

Why Not Auto Fire Engines?

If the familiar steam fire-engine is not an anachronism in this age of electricity and gas engineering, it comes perilously near it. In view of the remarkable progress in motor-driven vehicle design and construction during the past few years, it seems rather odd that the old-time fire engine, with its profusion of inutile polished surfaces and its inconsistent capacity for belching forth amazing volumes of carbon dioxide has not been ere now threatened with extinction by one or the other of the principal types of automobile, or a combination of the two. It requires no great imaginative power to discern the advantages that could be embodied in an automobile fire engine of the combination type, for example, as compared with the ancient form now persisting. With an internal combustion engine driving a direct-current dynamo at constant speed, and motors supplied from this dynamo and driving the traction wheels and pumps of the outfit, a speediness and facility of control could be obtained which is absolutely out of the question with the old type of machine. Some little work has been done in this or a similar direction, we believe, but no tangible results are manifest. Of course, one serious obstacle in the way of progress in this particular field is the difficulty in producing the necessary "change of heart" in the proper municipal officials.

DESIGN AND CONSTRUCTION OF SMALL DYNAMOS AND MOTORS.

BY CECIL P. POOLE.

Commutator and Brush Holders.

By far the wisest course for the amateur dynamo or motor builder to pursue with regard to the construction of commutators and brush-holders is to buy these from some of the many manufacturers of such apparatus. In buying a commutator it is necessary to give the manufacturer (1) the diameter of the barrel, (2) the width of barrel face parallel to the shaft, (3) the diameter over the lugs, (4) the diameter of the shaft-hole, (5) the voltage of the machine, and (6) the current per commutator segment. Although each

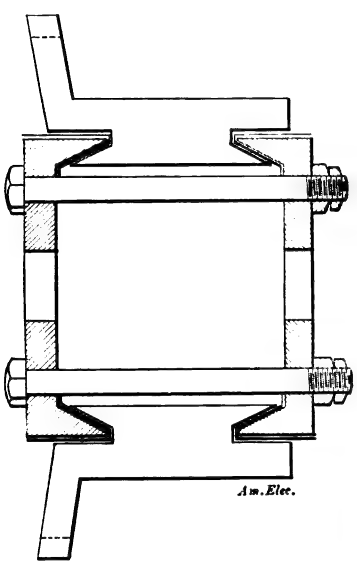

FIG. 24.

brush will doubtless touch two or more segments at any instant, it is well to put the current per segment at twice the current per armature wire when ordering a commutator.

For brush holders, the builder cannot do better than buy a set of the familiar Bayiis reaction holders and arrange his brush-holder mounting to suit them.

However, if the ambitious amateur is determined to make his own commutator and brush-holders the types herein described will be found easier to construct than the more conventional forms with which commercial machines are commonly equipped. Commutators of larger sizes may be constructed readily and cheaply along the lines indicated in Figs. 24, 25 and 26; that is to say, commutators which are large enough in diameter to give room for the

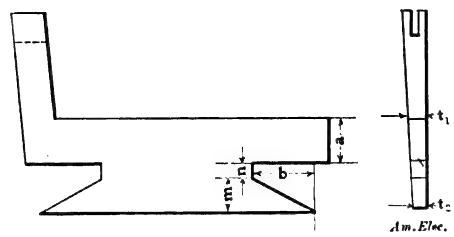

FIG. 26.

clamping bolts between the under edges of the segments and the shaft. The segments are held together by two cast-iron plates or discs and four finished machine bolts as indicated in Fig. 24, which shows two diametrically-opposite segments, two of the four bolts, and cross-sections of the clamping plates. The mica insulation between the flanges of the plates and the recesses in the ends of the commutator bars is indicated by the thin black lines between the opposing faces of these parts. This insulation should in all cases be not less than 1-16 inch thick. The essential dimensions on the end-plates and each segment are given in Table XV, reference letters being used to identify the various diameters and lengths. The distance, lengthwise of the bar, between the recesses in each commutator bar should be approximately one-half as great as the width of the commutator face parallel to the shaft.

TABLE XV.
Commutator Data.

Barrel diam., D_k =	Up to 3"	3" to 6"	Over 6"
Dimension a =	1/4"	3/8"	5/8"
Dimension b =	3/8"	1/2"	5/8"
Dimension c =	3/16"	5/16"	3/8"
Dimension m =	3/16"	1/4"	5/16"
Dimension n =	5/32"	5/32"	5/32"
Diameter D_{ka} =	D_k — 13/16"	D_k — 1 1/16"	D_k — 1 9/16"
Diameter D_{kb} =	D_{ka} — 1/8"	D_{ka} — 1/8"	D_{ka} — 3/16"
Diameter D_{kc} =	D_{kb} — 3/8"	D_{kb} — 1/2"	D_{kb} — 5/8"
Diameter D_{kd} =	D_{kc} — 1/4"	D_{kc} — 5/16"	D_{kb} — 3/8"
Diameter D_{kh} =	17/64"	25/64"	33/64"
Diameter D_{ko} =	D_s — 7/64"	D_s — 7/64"	D_s — 7/64"
Thickness t_1 = in all cases ($\pi \times D_k \div$ No. of bars) — 0.03"			
Thickness t_2 = in all cases ($\pi \times D_{kc} \div$ No. of bars) — 0.03"			

The mica strips between adjacent bars *must* be 30 mils thick and absolutely uniform.

The building up of the commutator is a trying job. The bars must be assembled loosely, with the mica strips between them, and gradually drawn together radially until the mass is perfectly tight. This is easiest done by first setting the bars on end on a level surface, in a hole in a block of wood about one-half as thick as the commutator face is wide, so that half of each segment stands above the surface of the block; and then drawing the segments centerward by means of screws in a ring of iron having a bore about 1½ inches greater than the diameter of the commutator barrel is to be. Curved shoes must be interposed between the screw points and the commutator bars to prevent gouging the latter. This assembling ring with screws and shoes is shown in Fig. 27. It will be noticed that the ring has flanges which extend beyond the heads of the set screws; these are for the purpose of chucking the ring for turning up the commutator, and in tightening up the set screws when assembling the segments care must be taken to keep the rough circle described by the outer faces of the segments concentric with the assembling ring.

When the segments have been drawn toward the center of the mass as tightly as possible, the assembling ring is chucked in a lathe and the inner circle of the segment edges trued up; next, the recess in the end then exposed must be tooled to the proper dimensions. The assembling ring is then reversed in the chuck and the recess in the other end tooled out to size. The end-plates are then put in place, with their intervening insulation, and the clamping bolts tightened up solid; then the whole structure is mounted on a mandrel, the assembling ring removed, and the commutator barrel and lugs turned down to size. It will be obvious, upon consideration of the impossibility of centering the segments in the assembling ring with absolute accuracy, that much more allowance for finish must be made in the segment pattern than would be allowed for ordinary work.

For commutators larger than 2 inches

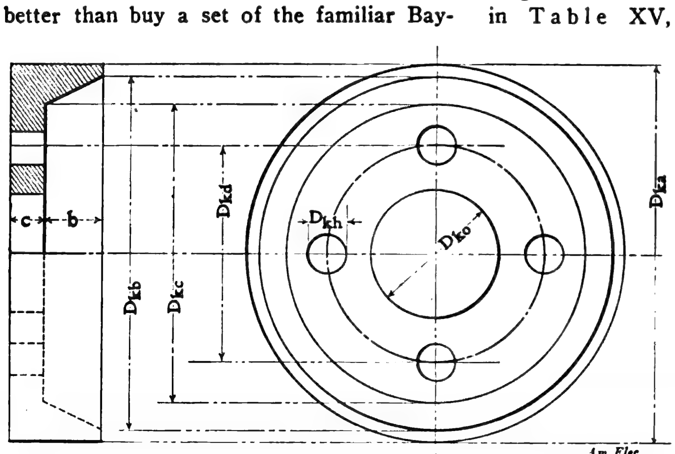

FIG. 25.

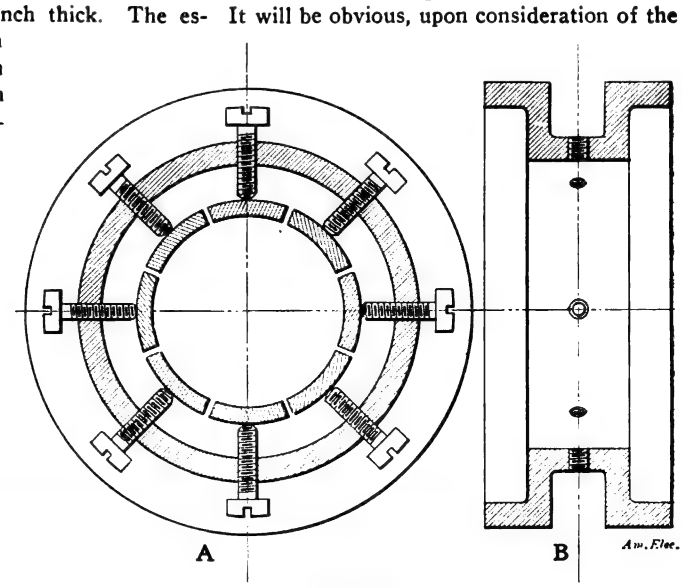

FIG. 27.

barrel diameter but not large enough to permit the construction shown in Fig. 24, the clamping plates should be made with central hubs projecting into the commutator almost far enough to touch each other, and the bolt-holes omitted. After the commutator segments have been tooled out on the inside and both ends, one of the clamping plates should be slipped on the shaft up against the shoulder of the *a* and *c* parts, the mass of segments (still held in the assembling ring) set into the flange of this plate, and the second plate then set in place in the outer end of the commutator and tightened up by means of a nut on the shaft, the outer end of the part, *c*, of the shaft having been threaded for this purpose.

For commutators of 2 inches barrel diameter or smaller, the easiest method is to cast the commutator in a solid piece and saw it into segments on a milling machine or with a milling attachment to a lathe. The solid casting should first be bored out to the diameter D_{kc} and mounted on a mandrel; then the ends should be finished up and a rough cut taken over the barrel face merely to true it with the finished recesses in the ends. Next, a hard wood mandrel should be made to fit the bore of the casting very snugly, the mandrel extending beyond the ends of the casting only far enough to give ample support to the edges of the metal around it. The casting may then be centered in a chuck, using curved shoes between the chuck jaws and

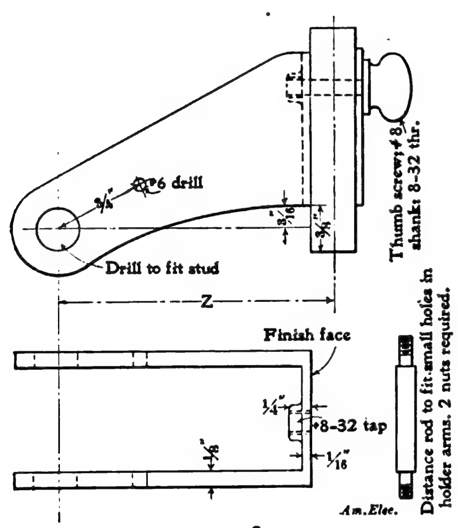

FIG. 28.

the casting which encircle the entire casting; the chuck jaws should catch only enough of the casting to hold it securely. The casting may then be slitted from the free end to a point well beyond the center of its length, using a saw 25 mils thick and cutting as many equidistant slits as there are to be commutator bars. Then the casting is to be reversed in the chuck and the other end slitted in the same way, the shoes under the chuck jaws serving to hold the segments in place during the final slitting of the casting. The slits last cut must, of course, match *absolutely* those first cut in the other end of the casting, so that the sides of the resulting segments will be true. The commutator is then assembled between the end plates without the use of an assembling ring, the nut on the shaft being relied on to draw the segments to place. During the tightening up of the nut, however, the faces of the segments should be tapped gently with a wooden mallet to assist the nut in overcoming the sliding friction between the beveled faces.

The easiest form of brush holder for the

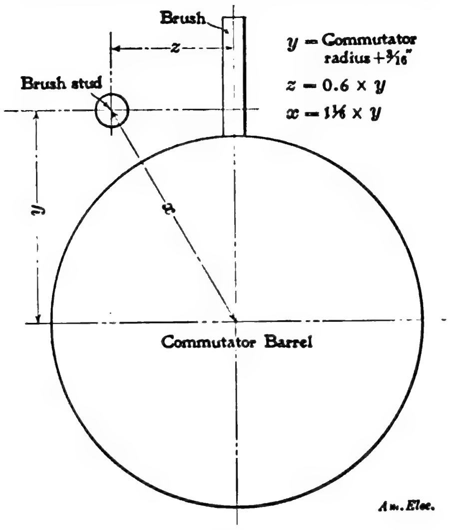

FIG. 30.

amateur to make is the pivoted type, shown in Fig. 28. This is mounted on the brush stud with its tension collar, Fig. 29, between its lugs and the spring in place. The carbon brush is bolted to the face of the holder with a single wing or thumb screw, a thin plate being used to distribute the pressure of the screw head. Fig. 30 shows how the distance from the center of the brush to the center of the pivot hole and the distance from the center of the shaft to the center of the stud are determined. The sketches give all necessary information as to dimensions and finish. The holder is of cast composition, of course.

THE TELEPHONE SUB-STATION AND ITS CONNECTION TO THE CENTRAL OFFICE.

BY A. DALLAM O'BRIEN.

By no means the least important problem that confronts the telephone engineer is the arrangement of the sub-station lines which radiate from the central office and the equipment which is necessary at the sub-station. The sub-station line has its beginning at the main distributing frame, as the connection from this point to the switchboard forms a part of the internal equipment of the exchange itself and simply furnishes a means of extending the outside line to the switchboard. The dividing line between the inside and outside portions of the sub-station line occurs absolutely at the arresters, which are located on the main distributing frame.

In large offices the outgoing sub-station lines are led from the arresters by means of cables to the underground conduits which enter the building. The size and number of pairs of conductors in these cables depend largely upon the length and number of the lines terminating at the office, the cables ranging from those having fifty pairs of conductors of No. 16 or No. 18 wire to those having four hundred pairs of No. 22 wire, these latter finding their principal field in the larger cities. The office manhole plays a most important part in the outside distribution system, as it is from this point that the subway leading to the office begins. The cables coming from the office are brought into this manhole and their conductors spliced to conductors in other cables by which they are led towards the sub-station.

It often happens that the location of a central office is such that the entering lines cannot all be brought in through one office manhole; in such cases several manholes are provided, each having a line of conduit leading from it to the office. There are a number of methods in common use, by means of which the underground lines are arranged for distribution to the sub-stations, and several of these methods will be described in detail.

The terminal pole block system is very largely used in cities and where the right of way over housetops is easily secured, furnishes a ready solution for the distribution problem. The territory to be served is divided into blocks and a terminal pole located preferably in a small street or alley as near the center of the block as possible. The main conduit line is connected by means of a single line of conduit running from a manhole in the main line to the base of the terminal pole. This single line is technically known as a lateral, and the conductors for serving the block are carried in a cable from the manhole in the main line to the base of the terminal pole, where the cable is brought up above the ground inside an iron pipe to a point on the pole some eight or ten feet above the ground level. From this point the lead-covered cable is carried up the side of the pole to within three or four feet of the top.

The top of the pole is equipped with a cable box which has a capacity of from fifty to two hundred pairs, according to the requirements of the block. The cable boxes for this class of work are provided with two sets of lugs or connectors, one set serving to carry the conductors from the cable and the other to carry the line wires leading to the sub-stations, the two sets being electrically connected by a fuse. The cable is ended at the base of the box with a pot-head and weather-proof wires spliced to the cable conductors and fanned out to the lugs or connectors on the cable side of the box. The terminal pole also carries an iron distributing ring on which are mounted glass insulators, the number of such insulators depending upon the diameter of the ring, which varies with the capacity of the cable box.

The sub-station lines are led from the line side of the box to the insulators on the ring, where they are connected to weather-proof wire conductors which lead directly to the sub-station, the insulators serving to take up the strain due to the span and to prevent any strain coming upon the wires in the cable box. It is, of course, advisable that the length of the span from the distributing pole to the sub-station be made as short as possible, although there are cases where spans of from 300 to 400 feet are necessary.

The span from the terminal pole is fastened to the outside of the sub-station in one of a number of ways. It may be terminated on pins mounted on a wooden trestle on the roof, or on a more durable structure of iron pipe, and from this point led down the side of the building wall to insulators fastened on the wall at the point of entrance to the building. Where the span is short the trestle may be dispensed with and the wires connected directly to the insulators on the wall. The entrance to the building is most conveniently effected through the top of a window-frame, holes being drilled through the frame and hard rubber tubing slipped through the holes, the tubing extending an inch or two on the outside. The line wires are brought into the sub-station through the tubing and are then led directly either to the protector or to the instrument: in the former case the wires to the instrument are led from the protector. The use

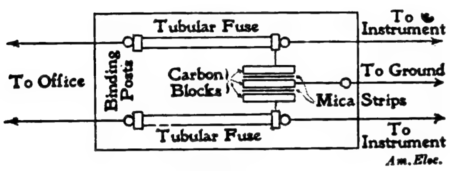

FIG. 1.

of the sub-station protector is not always necessary, but where the outside span crosses or comes in the vicinity of trolley wires or high-tension lines, it is absolutely necessary for the protection of the subscriber that provision be made at the sub-station to open the line in case of an accidental cross with a high-tension wire. The type of protector that is usually employed for this purpose is shown in Fig. 1, the fuses serving to protect the instrument from a heavy current; the carbon blocks, with their fusible plugs and ground connection to the center carbon, serve to afford an easy path to ground for the high-tension current which results from lightning discharges or from crosses with high-tension transmission lines.

Where a protector is employed, the wiring from the protector to the instrument is preferably done with twisted pairs which may be covered with an insulation to conform with the woodwork of the interior and thus avoid the unsightly appearance of two black wires. Where the line is led directly to the instrument, the twisted pair is spliced to the entering wires as close as possible to the point of entrance. A loop should be made in each conductor, on the outside of the building, the bottom of the loop hanging below the point of entrance to the hard rubber tubing; this feature affords a low point in the system from which rain water can readily drip and by means of which the passage of such water along the wire and its subsequent entry into the sub-station is avoided.

The efficiency of the protector depends to a very great extent upon the care and thoroughness with which the ground connection is made, and as a good ground is in most cases an easy thing to procure the connection should certainly receive careful attention. Probably the best means of making a connection of this kind in a sub-station is to run the ground wire from the protector to a water pipe. Carefully clean the outer surface of the pipe and wrap it with eight or ten turns of No. 16 bare copper

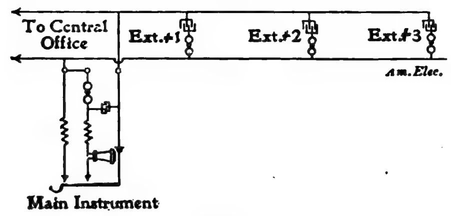

FIG. 2.

wire, the wire being soldered to the pipe wherever it is possible to do so. To the end of this coil the ground lead from the protector is spliced. It is very rare indeed that trouble arises from a connection of this kind. Where it is not possible to connect to a water pipe, a satisfactory ground may be obtained by connecting the lead from the protector to a copper plate or coil of copper wire buried in the ground at a depth of about three feet, care being taken to secure a place where there is some liability of continual dampness.

In the sub-station itself, there are many possible combinations and arrangements of instruments, which add to the satisfaction of the subscriber and to the efficiency of the telephone service from the standpoint of the user. The combinations and arrangements mentioned of course refer to the use of extension instruments or extension bells in connection with the main instrument on the exchange line. Where it is considered desirable that all telephone calls incoming to the sub-station should be answered from one point, but where the location of the instrument makes it necessary that the ringing of the telephone bell should be audible at a point remote from the telephone, the extension bell will serve every purpose, and for all practical purposes an unlimited number of extension bells may be connected on a sub-station line. The usual method of connecting these bells in the circuit is shown by the diagram in Fig. 2. In this instance a main instrument and three extension bells are shown connected to the circuit. The bells themselves are of the same type as the bell on the main instrument and are connected in parallel across the line circuit,

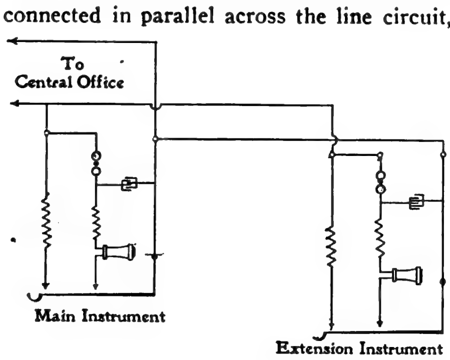

FIG. 3.

a switch usually being inserted in the branch circuits in order that the extensions may be rendered inoperative at will. It is, of course, apparent that by increasing the number of bells which are permanently bridged across the line, the resistance of the circuit will be decreased. The amount of current, however, which flows through each bell remains the same, whether there be two or ten extensions on the line. There are a great many ways of connecting extension instruments in order that calls to the station may be answered over any instrument at will, and in order also that any one of the instruments may be capable of being directly connected with the central office. In addition to these features, the circuits are oftentimes so arranged that the extensions may call the main instrument without the medium of the central office.

The simplest method of connecting extension instruments is shown in Fig. 3. Here the extension is bridged directly across the line; both the extension and main instruments being provided with bells, so that calls from the central office may be received on either instrument and the central office may be reached from either the extension or main station. There is nothing in this method of connecting instruments which limits the number that may be connected to a single line. There is, however, one feature which may at times prove disadvantageous, since the conversation which is being carried on at one instrument may be overheard at the other. Fig. 4 shows diagrammatically the same method of connecting the instruments except that the extension instead of being directly bridged across the line is connected by a switching key at the main instrument, so that when it is desirable the extension instrument may be entirely cut off from the line, while any

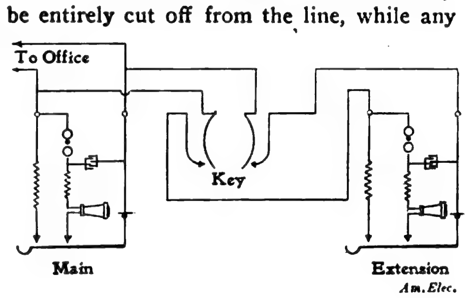

FIG. 4.

connection originating at the extension may be supervised from the main instrument.

It is not the usual practice for telephone companies to install extension instruments which are connected in such a way that conversation may be carried on between the main and extension instruments other than through the central office, but cases may arise where it is desirable to depart from this general rule, and a convenient method of accomplishing this end is shown in Fig. 5.

In this diagram it will be observed that the line from the central office is led to the instruments through the contacts of a switching key which is normally arranged so that the instruments are disconnected from the line, but at the same time, signals may be received at the main station through the bell which is bridged across the entering line from the central office and which has a condenser inserted in series with it. The operation of this arrangement will be easily understood. On an incoming call the signal is given by the perma-

nently bridged bell, and by throwing the switching key to the outer contacts the subscriber at the main instrument is placed in connection with the operator at the central office and the call may be received. Should the person desired be more conveniently reached at the extension station, it is only necessary for the person at the main instrument to request the operator to ring over the line, at the same time replacing the receiver of the main instrument on the hook. When the operator rings, the bells at both stations are actuated and the desired connection readily obtained. As previously stated, the normal position of the switching key is that with the line to the central office disconnected from the instruments. When this condition is obtained the diagram shows that the battery, the terminas of which are connected to the inner contacts of the key, is bridged across the line, thus connecting the two stations. Should one station desire to signal the other, the operation of the hand generator causes a current to flow through the bell of the station desired and makes the connection possible. The ringing current in this instance is prevented from finding its return circuit through the battery by means of the impedance coils, one of which is connected on either side of the source of current supply. These coils are of low resistance, but are wound with a number of turns on an iron core and have in consequence a high impedance to the alternating ringing current and prevent the circuit from being completed through the battery when the called station has responded to the signal.

It will be noted that the talking circuit between the two instruments is of the simplest character and comprises a direct line between the two stations with a battery bridged across it. The advantages of this arrangement for some sub-stations lie in the fact that the extension instrument is at all times under the control of the main station, that no calls for outside points can originate except with the knowledge of the subscriber at the main instrument, and that communication may be quickly and readily obtained between the two stations. It follows very naturally that in but rare cases two extension instruments are the maximum number which are connected to a single line: the reason for this is a two-fold one. In the first place, where the necessity exists for more than three instruments in a sub-station there is usually a considerable use of the line, and consequently, the liability is great that two stations may desire to obtain connections at the same time, thus delaying calls. In the second place, the operating telephone companies are desirous of increasing their traffic as much as possible and avoiding lost or delayed calls. In cases where it might be possible to consider the installation of a larger number of extension instruments it is the policy of the telephone companies to recommend and insist upon the use of private branch exchanges, which permit of easy intercommunication between the extension stations and, at the same time, provide for more than one connecting trunk line to the central office.

As the requirements of a sub-station increase the utility and advantages of the private branch exchange as an auxiliary to the central office become more and more apparent, and with the present conditions which govern the devlopment of the telephone sub-station the private branch exchange may unquestionably be considered as the limit towards which the sub-station is constantly tending.

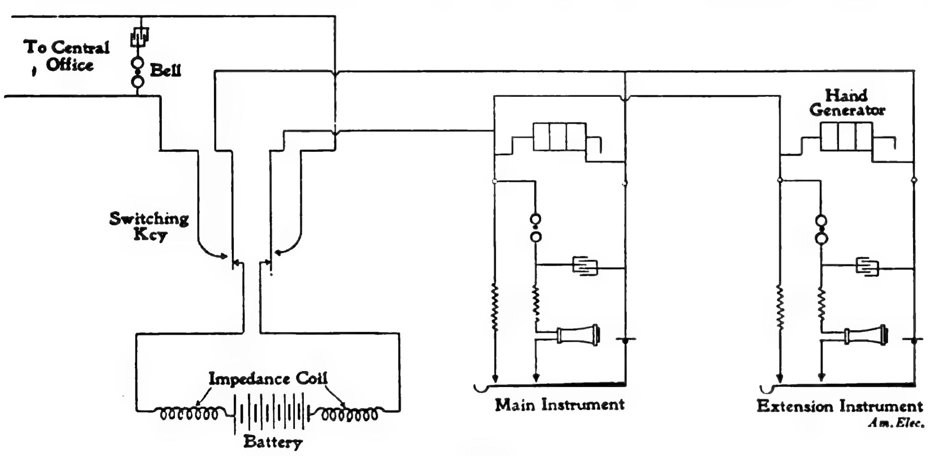

FIG. 5.

GENERATOR COMMUTATOR REPAIRS.

BY ARTHUR B. WEEKS.

When a suspicious spark begins to manifest itself on a generator commutator, the cause should be sought at once. The construction of some generator connections is such, that the flat connecting strips are free to vibrate, and sooner or later they begin to weaken and finally break off. The sparking commences with the make and break of the connection, and if not discovered and repaired, the commutator will require turning. If a wooden wedge be used to pry slightly between the vertical connections in line with a bar which shows any discoloration, the fault will usually be located at once. Undue prying, however, is injurious and must be avoided. The trouble should be located as speedily as possible. It should not be laid to a bad brush, and ignored, but the machine should be shut down as soon as convenient and the trouble investigated.

The connection usually breaks at the surface of the commutator, as at *A*, Fig. 1. The connector lugs of strip copper are frequently separate from the commutator bars and are riveted and soldered in place. They open out at the top to admit the arma-

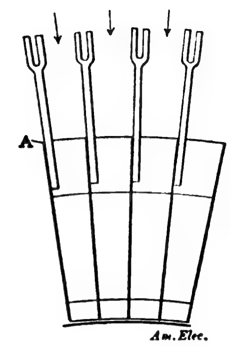

FIG. 1.

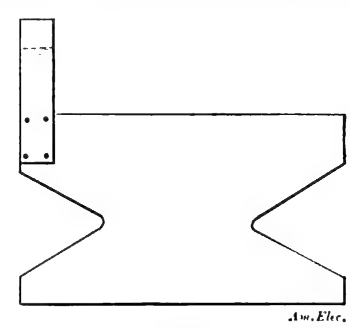
ture conductors, the number depending upon the system of winding. Fig. 2 shows a side view of a commutator bar and an attached lug.

To repair such a break requires judgment and skill in the use of a chisel. The first thing to be done is to push asbestos in between adjacent bars, so that heat from the torch will not affect them. Asbestos should also be worked in at the back if possible, for the purpose of keeping solder from places where it would cause trouble. Then unsolder the armature leads from the lug and remove the latter. Next, with specially made cape chisels, cut a slot in the commutator bar for a new lug. Great care and skill are required not to destroy the mica insulation between the segments. The slot should be cut one-quarter to three-eighths inch deep. The connector is then soldered in place.

With care a satisfactory connection can be made in this way, which will last well.



FIV. 2.

If it does not last, the trouble in almost every case is due to poor soldering. Short circuits sometimes occur after this operation, because of solder falling in at the back and lodging on lower connections. In large machines, especially rotary converters, the excessive current flowing is quite likely to melt this solder, and the machine may buck, throwing out the melted solder, after which it may be all right again. While the bar connector is out, however, asbestos should be packed in back of it to prevent this occurrence, which may be a serious affair.

All surplus solder and the asbestos packing should be removed after the connection is finished, and the connections cleaned with compressed air. The armature should be turned over slowly, air being applied all the while. Even this may not remove all solder, and things may be running along nicely, when a sudden great flash at the brushes occurs, and melted solder is found on the generator frame in line with the commutator connections.

Fig. 3 shows an armature of this kind, which has just been rewound, the band

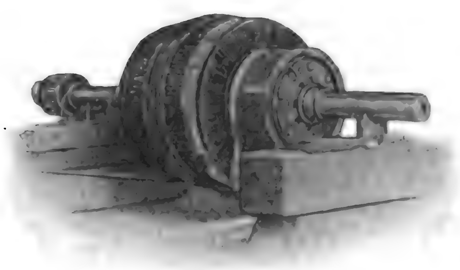


FIG. 3.—ARMATURE OF ROTARY CONVERTER.

wires being put on while the armature is turned by means of a hand winch. A rope from the winch is wound around the armature several times, as shown, and the winch lever turned, giving motion to the armature.

Before soldering the armature leads into the radial commutator lugs, tapered hardwood wedges should be driven in between the connectors all around the armature, as indicated by the arrows in Fig. 1. The soldering flux is then applied, and the solder put on with torches. Before connecting and soldering, a piece of cloth should be arranged back of the commutator to catch surplus solder, and when the work is completed, this can be drawn out between the spider legs at the back, by means of strings previously fastened to the cloth and passed out at the back of the armature.

After soldering the excess solder is turned off when the armature is replaced in the machine, or swung in a lathe. Of course, in its present condition, current cannot be applied to turn it. If it is the armature of a rotary converter, which is true of the one illustrated, the starting motor can drive it. The wedges are then removed. Finish the connections finally with a good black air-drying insulating paint.

ECONOMY OF FEED-WATER HEATING.

It is, of course, a matter of common knowledge among steam engineers that heating the feed-water of a boiler before delivery into the boiler effects a considerable saving in fuel, or, what amounts to the same thing, enables the boiler to evaporate more water per pound of coal. The percentage of increase in water per pound of coal is not the same as the percentage of decrease in coal per pound of water, but the difference is usually small. For example, if the amount of water evaporated per pound of coal is 10 per cent. greater by heating the feed-water, the reduction in coal per pound of water evaporated is not 10 per cent., but 9 per cent., or, academically, 9.1919 per cent.

A table of factors of evaporation furnishes a most convenient means of estimating the saving in fuel or the increase in steaming capacity due to heating the feed-water. In order to ascertain approximately the saving in fuel it is only necessary to divide the factor of evaporation corresponding to the conditions of heated feed-water by the factor corresponding to the conditions with unheated feed and multiply the result by the coal consumption with unheated feed. For example, if a boiler is operated at 120 lbs. gauge pressure with unheated feed-water at a temperature of 70° Fahrenheit, the factor of evaporation is 1.1915; if the feed-water were heated to 200° Fahrenheit, the factor would be 1.0561. Dividing this last factor by the first one gives 0.886, so that the coal per pound of water with feed-water at 200° Fahr. would be 0.886 × the coal per pound of water with feed-water at 70° Fahr. Or, if the coal consumption under existing load conditions is 10 tons per day, the amount burned with the feed-water heated to 200° Fahr. would be only 8.86 tons per day.

Again, if the feed-water is heated by exhaust steam from auxiliaries which is insufficient to get the temperature above 150° Fahr., for example, and the working boiler pressure is 120 lbs. per sq. in., the evaporation factor will be 1.1083. If by decreasing the efficiency of the auxiliaries their steam consumption would be increased so that their exhaust steam would heat the feed-water up to 210° Fahr., the factor then would be 1.0456, and the required fuel would be $1.0456 \div 1.1083 = 0.943$ of the quantity burned with the lower feed-water temperature. Whether or not it would pay to use less efficient auxiliaries, therefore, would depend on the cost of coal, and also on the efficiency of the feed-water heater to some extent. This problem is quite a complex one, and not within the scope of the present article, the object of which is merely to point out the application of the table of factors of evaporation to the question of fuel saving by feed-water heating.

If one should desire to reverse the problem and ascertain the increase in water that can be evaporated per pound of coal it is only necessary to reverse the relationship of the two evaporation factors; that is to say, divide the larger factor by the smaller and multiply the result by the present water evaporation to find the water that could be evaporated per pound of coal with the higher feed-water temperature.

FACTORS OF EVAPORATION.

American Electrochemical Society.—The next annual meeting of the American Electrochemical Society will be held at Boston and Cambridge, Mass., April 25, 26 and 27. The program will include papers by Dr. J. W. Richards, Dr. H. S. Carhart, Dr. W. D. Bancroft, Dr. Carl Hambuechen, Prof. Blake, Prof. H. R. Carveth, Arvid A. Reuterdahl and C. G. Richardson. A number of excursions will be held and some interesting exhibits will be made at the convention headquarters. The hotel headquarters will be The Lenox, Boyleston and Exeter Streets, Boston, Mass.

DISEASES OF ELECTRICAL MACHINERY.

BY F. B. CROCKER AND S. S. WHEELER.

The promptness with which a difficulty with electrical machinery may be overcome will always have much to do with the success of the plant. The following statement of troubles or "diseases," with their symptoms and remedies for the various types of generators and motors, has been prepared to facilitate the detection and elimination of these troubles. It is evident that the subject is somewhat complicated and difficult to handle in a general way, since much depends upon the particular conditions in any given case, each of which must be stated in such a way as to distinguish it from all others. Nevertheless, a great deal can be covered by systematic treatment. It may frequently happen that a trifling oversight, such as allowing a wire to slip out of a binding-post, will cause as much annoyance and delay in the use of electrical machinery as the most serious accident. Other troubles, equally simple but not so easily detected, may also occur. In such cases even a slight knowledge on the part of the man having the machine in charge, guided by a correct set of rules, will enable him to overcome the difficulty immediately and save much time, trouble and expense. The principal object should always be to separate clearly the various causes and effects from each other. A careful and thorough examination should be first made, and as far as possible one should be sure of the facts, rather than attempt to guess what they are and jump at conclusions. Of course general precautions and preventive measures should be taken *before* any troubles occur, if possible, rather than wait until a difficulty has arisen. For example, one should see that the machine is not overloaded and should make sure that the oil-cups are not empty. Neglect and carelessness with any machine are usually and deservedly followed by accidents of some sort.

A. Sparking at the Commutator.

This is a common trouble that is not very objectionable if moderate in amount and duration. Beyond these limits, however, it is likely to become serious because it burns and roughens the commutator, thus aggravating the difficulty. At the same time it produces heat that may spread to and injure the armature or bearings. Any machine having a commutator is liable to spark, including practically all direct current and some alternating current machines. Most alternating current machines have collecting rings which are not likely to spark; but rotary converters, self-exciting or composite wound alternators, as well as series and other types of self-starting, single-phase motors, require a commutator which may spark. This trouble can be prevented in most cases by proper design and construction. The inductance per section must be limited by correct form of slot, sufficient number of sections and strength of magnetic field. Carbon brushes also tend to reduce sparking. A certain amount of sparking occurs normally in most constant-current dynamos for arc lighting, where it is not very objectionable, since they are designed to stand it, and the current is small.

Cause 1.—Armature carrying too much current, due to (*a*) overload (for example, too many lamps fed by a generator, or too much mechanical work done by a motor); a short circuit, leak or ground on the line may also have the effect of overloading a generator; (*b*) excessive voltage on a constant-potential circuit or excessive amperage on a constant-current circuit. In the case of a motor any abnormal friction due to the armature striking or rubbing against the

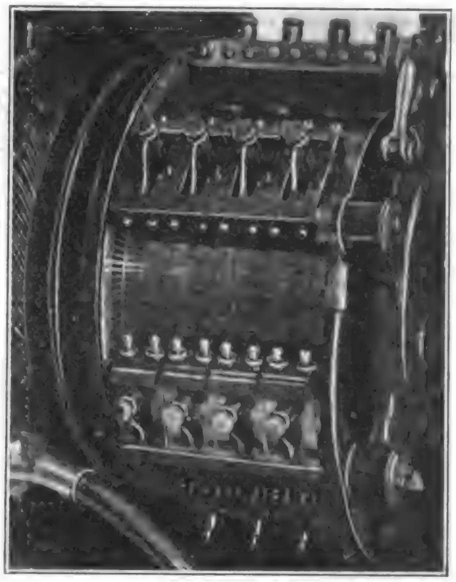

FIG. 1.—COMMUTATOR IN GOOD CONDITION.

pole pieces, or the shaft not turning freely will have the same effect as an overload. It often happens, especially with a new machine, that an overload, short-circuit, etc., creates a very excessive current. This may produce, even if only momentary, a burned and rough spot on the commutator.

Symptom.—If the excessive current flows for any considerable time the whole armature becomes overheated. The belt (if used) is very tight on tension side, sometimes squeaking, because it slips on the pulley. Overload, due to friction, may be detected by stopping the machine, and if not too large, turning it slowly by hand or with a lever, the load being disconnected. A convenient and sensitive test for any size of machine is to determine the current required to run the armature free (operating as a motor), which should not be more than about 4 or 5 per cent. of the current at rated load, except in machines of 10 horse-power or less, which may take 6 to 10 per cent. The field current should be measured first, with the armature circuit open, and deducted from the ammeter reading. (See "Heating of Bearings" and "Noise.")

Remedy.—(*c*) Reduce the load, or eliminate the short circuit, leak, or ground on the line; (*d*) decrease the size of driving pulley, or (*e*) increase the size of driven pulley; (*f*) decrease magnetic strength of the field in the case of a dynamo or increase it in the case of a motor. If excess of current cannot satisfactorily be overcome in any of the above ways, it will probably be necessary to change the machine or its winding. Overload due to friction is eliminated as described under "Heating of Bearings" and "Noise," Cause 2.

If the starting or regulating rheostat of a motor has too little resistance, it will cause the motor to start very suddenly and spark badly at first. The only remedy is to increase this resistance.

Cause 2.—Brushes not set at the neutral point.

Symptom.—Sparking varied by shifting the brushes with rocker arm or ring.

Remedy.—Carefully shift the brushes backwards or forwards until sparking is reduced to a minimum. If only slightly out of position, heating alone may result, the conditions not being bad enough to show sparking. If the brushes are not exactly opposite, or in a four-pole machine 90° apart, and so on, they should be made so, the proper points of contact being determined by counting the commutator-bars, by measuring with a strip of paper, or by separately adjusting each set of brushes to its minimum sparking point.

The usual position for the brushes is opposite the spaces between the pole pieces, but in some machines the brushes must be set in some other position which can be determined by finding the non-sparking or minimum sparking points. If the brushes are placed exactly wrong, namely, half-way toward the proper position for the next set of brushes, they will cause a dynamo to fail to generate and a motor to fail to start, and in the latter case the fuse will blow or the circuit-breaker open.

See "Dynamo Fails to Generate," Cause 6.

Cause 3.—Commutator rough, eccentric or has one or more "high bars" projecting beyond the others, or one or more flat bars, commonly called "*flats*," or *projecting mica*, any one of which will interfere with good

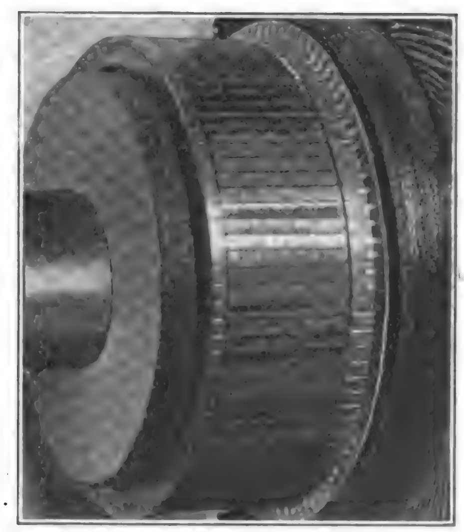

FIG. 2.—COMMUTATOR HAVING HIGH MICA AND BLACKENED BARS.

contact of the brushes or cause them to be thrown out of contact with the commutator (Fig. 2). Flat or high bars in machines usually result from looseness of the nut or screws which hold the commutator parts together. The effect of eccentricity may be produced by the shaft being loose in the bearings while the commutator is perfectly true on shaft. This will allow the whole ar-

mature to chatter when running at full speed. Hard mica between the bars which does not wear as rapidly as the copper will tend to throw the brushes off.

Symptom.—Note whether there is a glaze or polish on the commutator, which shows smooth working; touch the revolving commutator with tip of finger-nail and the least roughness is perceptible, or feel of the brushes to see if there is any jar. If the machine runs at high voltage (over 250) the commutator or brushes should be touched with a small stick or quill to avoid danger of shock. In the case of an eccentric commutator, careful examination shows a rise and fall of the brush when the commutator turns slowly, or a chattering of the brush when running fast. Sometimes by sighting in line with brush contact one can see daylight between the commutator and brush, because the latter jumps up and down.

Remedy.—Smooth the commutator with a fine file or fine sandpaper, the latter being applied by a block of wood which exactly fits the commutator. Carborundum paper or a carborundum hone is also applicable, but *emery should never be used.* In all cases

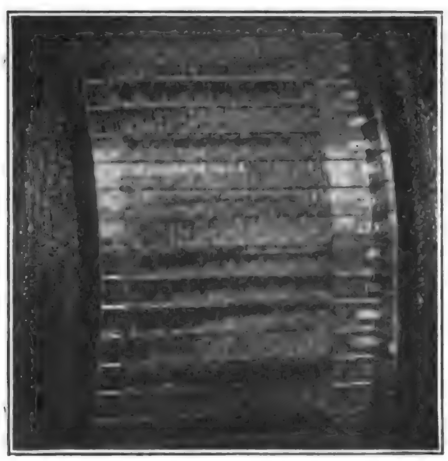

FIG. 3.—BURNED COMMUTATOR.

particles of grit or copper should be very carefully removed before the brushes are allowed to touch the commutator. To set up a loose nut on a commutator requires considerable force, a long wrench being used. The effective length of a wrench may be increased by slipping over the handle a piece of iron pipe. Screws may be tightened by means of a heavy screw-driver. If the bearing is loose, put in a new one. If the commutator is very rough or eccentric, the armature should be taken out, put in a lathe, and the commutator turned off. Large machines may be provided with a slide-rest attachment or grinding device, so that the commutator can be turned off or ground true without removing the armature. This is clamped on the pillow-block or rocker ring.

For turning off a commutator, a diamond-pointed tool should be used, with a very sharp and smooth edge, only an exceedingly fine cut being taken off each time in order to avoid catching in or tearing the copper, which is very tough. The surface is then finished by applying a "dead smooth" file while the commutator revolves rapidly in the lathe. Any particles of copper should then be carefully removed from between the bars.

In order to have the commutator wear smooth and work well, it is desirable to have the armature shaft move freely back and forth about an eighth of an inch in the bearings, but in some machines this is not practicable. A commutator should have a dull glaze of a brown or bronze color. A very bright or scraped appearance does not indicate the best condition. Sometimes it is desirable to apply a very little vaseline or a drop of oil to a commutator which tends to become rough. Much oil is very bad, and causes the following trouble.

Cause 4.—Brushes make poor contact with commutator.

Symptom.—In general, all of the cases under Cause 3 will have this effect, but the two classes are usually distinguishable. Close examination shows that brushes touch only at one corner, or only in front or behind, or there is dirt on the surface of contact. Sometimes, owing to the presence of too much oil or from other causes, the brushes and commutator become very dirty, and covered with smut. They should then be carefully cleaned by wiping with a slightly oily rag or one moistened with benzine, or by other means. In some cases a commutator becomes sticky, which causes the brushes to "chatter," and, therefore, to make poor contact.

Occasionally a "glass-hard" carbon brush is met with. It is incapable of wearing to a good seat or contact, and will touch only at one or two points. Some carbon brushes are of abnormally high specific resistance, so that they do not make good electrical contact. In both cases new brushes should be substituted. Vibration (Sparking, Cause 10), also interferes with good brush contact.

Remedy.—Carefully clean the commutator, also fit, adjust and clean the brushes until they rest evenly on the commutator, with the maximum surface of contact and with sure but not too heavy pressure. In order to fit copper brushes properly on the commutator, a brush jig is required. Carbon brushes may be fitted perfectly by drawing a strip of sandpaper back and forth between them and the commutator while they are pressing down. A band of sandpaper may be pasted or tied around the commutator, and the armature slowly revolved by hand or by power and the brushes pressed upon the commutator.

It sometimes happens that the brushes make poor contact, because the brush-holders do not work freely.

Cause 5.—Short-circuited or reversed coil, or coils in the armature.

A short-circuit is often called a "short" and sometimes a "cross." The former term, however, applies properly to an accidental connection between conductors belonging to the same circuit, while the latter is applied to an accidental contact between two separate lines or circuits. A "flying" short-circuit is one that exists only when the machine is running, being caused by centrifugal force.

Symptom.—A motor will draw excessive current, even when running free without load. A generator will require considerable power, even without any external load. For reversed coil see "Heating of armature," Cause 6.

The short-circuited coil is heated much more than the others, and is very apt to be burned out entirely; therefore, the machine should be stopped immediately. If it is necessary to run the machine to locate the short-circuit, one or two minutes is long enough, but may be repeated until the short-circuited coil is sufficiently warmed to be found by feeling the entire surface of the armature.

A screw-driver or other iron or steel tool held between the pole pieces near the revolving armature vibrates very perceptibly as the short-circuited coil passes. Almost any armature, particularly one with teeth, will cause a slight but rapid vibration of a piece of iron held near it, but a short-circuit produces a much stronger effect only *once* per revolution. Care should be taken not to allow the piece of iron to be drawn in and jam the armature.

The current pulsates and the torque is unequal at different parts of a revolution, these being particularly noticeable when several coils are short-circuited or reversed and the armature turns rather slowly. If a large portion of the armature is short-circuited the heating is distributed and more difficult to locate. In this case a motor runs very slowly, giving little power, but having full field-magnetism. A short-circuited coil can also be detected by the drop-of-potential method. (For generators, see "Dynamo Fails to Generate," Cause 3.)

A "flying" short-circuit may not have any effect when the armature is standing still. It can often be forced to show itself momentarily, by pounding the armature core or the end of the shaft with a mallet or stick of wood. It is detected by the drop-of-potential method which would indicate intermittent variations in resistance.

Remedy.—A short circuit is often caused by a piece of solder or other metal getting between the commutator bars or their connections with the armature, and sometimes the insulation between or at the ends of these bars is bridged over by a particle of metal. In any such case the trouble is easily found and corrected. If, however, the short-circuit is in the coil itself, the only effective remedy is to rewind the coil.

One or more "grounds" in the armature may produce effects similar to those arising from a short-circuit. (See Cause 7.)

Cause 6.—Broken circuit in the armature.

Symptom.—Commutator flashes violently while running, and the commutator bar nearest the break is badly cut and burned; but in this case no particular armature coil will be heated as in the last case (Cause 5), and the flashing will be very much worse, even when turning slowly. This trouble, which might also be confounded with a bad case of "high bar" in, or eccentricity of the commutator ("Sparking," Cause 3), is distinguished therefrom by slowly turning the armature, when violent flashing will continue if the circuit is broken, but not with an eccentric commutator or even with a "high bar," unless the latter is very bad, in which case it is easily felt or seen. A very bad contact at some point would have almost the same effect as

a break in the circuit. In the case of a so-called "flying break" the circuit is only open when the machine is running, the effect of centrifugal force.

Remedy.—A break or bad contact may be located by the "drop" method or by a continuity test, while the armature is not running. Under these conditions a "flying break" does not manifest itself, but may be made to do so momentarily by pounding the armature core or the end of the shaft with a mallet or stick of wood, as in Cause 5. The trouble is most often found where the armature wires connect with the commutator, and not in the coil itself, and the break may be repaired or the loose wire properly connected and fastened. When the trouble is due to a broken commutator connection, which cannot be repaired immediately, the disconnected bar may be temporarily connected to the next by solder; or the brushes may be "staggered" by putting one forward or the other backward so as to bridge over the break. It may be impracticable to "stagger" radial brushes, but usually a brush is thick enough to make contact with more than one commutator bar. If the break is in the coil itself, rewinding is generally the only cure. But this may be remedied temporarily by connecting together by wire or solder the two commutator bars or coil terminals between which the break exists. It is only in an emergency that armature coils should be cut out or commutator bars connected together, or other makeshifts resorted to, but it sometimes avoids a very undesirable stoppage. A very rough but quick and simple way to connect two commutator bars is to insert a copper peg or wedge, or to force the metal of the bars together across the mica insulation at the end of the commutator. This should be avoided if possible, but if it has to be done in an emergency the bruised material can afterward be picked out and the cavity filled in with wood. In carrying out any of these methods care should be taken not to short circuit any other armature coil, which would produce sparking (Cause 5).

Cause 7.—Ground in the armature.

Symptom.—Two or more "grounds" (accidental connections between the conductors on the armature and its iron core or the shaft or spider) would have practically the same effect as a short-circuit (Cause 5), and should be treated in the same way. A single ground would have little or no effect, provided the circuit is not intentionally or accidentally grounded at some other point. On an electric railway (overhead trolley) or other circuit which employs the earth as the return conductor, or a three-wire system with the neutral conductor grounded, one or more grounds in the armature would allow the current to pass directly through them, and would cause the machine to spark and have a very variable torque at different parts of a revolution.

Remedy.—A ground may be detected by testing with a magneto bell. It may be located by the drop-of-potential method. Another way to locate it is to wrap a wire around the commutator so as to make connection with all of the bars, and then connect a source of current to this wire and to the armature shaft (by pressing a wire upon the latter). The current will then flow from the armature conductors through the ground connection and the magnetic effect of the armature winding will be localized at the point where the ground is. This point is then found by the indications of a compass needle slowly moved around the surface of the armature. The current may be obtained from a storage battery or from the circuit, but should be regulated by lamps or other resistance so as not to exceed the normal armature current. The armature core may be more or less insulated from the shaft and ground by the insulation between the laminæ, in which case one contact with the conductors would not have the effect of a ground. Sometimes the ground may be in a place where it can be corrected without much trouble, but usually the particular coil and often others have to be rewound. A ground will be produced if the insulation is punctured by a spark of static electricity, which may be generated by the friction of the belt; in fact, a belt usually gives off electric sparks while running. If the frame of the machine is connected to the earth the static charge will flow away harmlessly, but such grounding by means of a good conductor is sometimes undesirable. In those cases the frame may be connected to the earth through a Geissler tube, a wet thread, a heavy pencil-mark on a piece of unglazed porcelain, or other very high resistance which will carry off the static charge of very high potential and almost infinitesimal quantity, but will not permit the passage of any considerable current that might cause trouble. Large direct-connected machines are almost necessarily grounded.

Cause 8.—Weak magnetic field.

Symptom.—Pole pieces are not strongly magnetic when tested with a piece of iron. Point of least sparking is shifted considerably from normal position, due to relatively strong distorting effect of armature reaction. Speed of a shunt motor is usually high unless magnetism is very weak or *nil*, in which case it may run slowly, stop, or even run backwards. A generator fails to produce the full voltage or current.

The particular cause of trouble may be found as follows: A *broken circuit* in the field of a motor is found by purposely opening the field circuit at some point, taking care first to disconnect the armature (by putting wood under the brushes, for example), and to use only one hand, to avoid shock. If there is no spark when circuit is thus opened, there must be a broken circuit somewhere. Usually a *short-circuit* is confined to one magnet, and will therefore weaken that one more than the others, and a piece of iron held midway between the pole-pieces will be be attracted to one more than to the other. It may be found by the drop-of-potential or other method to determine whether one coil has considerably less resistance than any of the others. It is highly improbable that simultaneous short circuits would affect two or more coils equally. It is to be noted that a short circuit in one of the field coils, which are usually in series, causes that coil to be heated *less* than the others. *"Grounding"* is practically identical with short-circuiting, but one ground will not produce this effect until another occurs. A double ground, through which the current finds a complete circuit, is equivalent to a short-circuit. With overhead trolley electric railways a ground return is used, and the neutral conductor of three-wire systems is often grounded, in which cases one ground may be sufficient to cut out one or more field coils.

A field coil reversed and opposed to the others will weaken the field magnetism, and cause bad sparking. This may be detected by examining the field coils to see if they are all connected in the right way, or by testing with a compass needle to find whether the poles are alternately N. and S. (See "Dynamo Fails to Generate," Cause 4.) The series-coil of a compound-wound machine is often connected wrongly, and has the effect of forcing down the voltage the more the load is increased instead of raising it.

Remedy.—A broken circuit or a short-circuit or a ground is easily repaired if external or accessible. If it is internal, the only remedy is to replace or rewind the faulty coil. A shunt motor will spark badly in starting if the armature is connected before the field. This may be avoided by proper arrangement and manipulation of the switches. If the voltage is too low on the circuit, it is likely to cause sparking in a shunt generator or motor; and if it cannot be raised the resistance of the field circuit should be reduced by unwinding a few layers of wire or by substituting other coils.

To suit the speed of an engine or on account of a mistake in the size of pulleys or gearing, the speed of a generator may be higher than that at which it was designed to run. In such a case the field is necessarily weakened by means of its rheostat in order to obtain the rated voltage, thus producing a tendency to spark. The only remedy is to reduce the speed to the prescribed value. The same difficulty may occur in a shunt motor which is run above the rated speed by weakening its field. To avoid sparking it may be necessary to strengthen the field and change the pulley or gearing ratio or the speed of the driven machine to suit the diminished speed of the motor, unless the latter was specially designed to operate with weakened field in order to vary its speed. This method is now commonly employed, but is not applicable to ordinary types of shunt motor working at or near full torque. By reducing the load or current in such a machine below the rated amount, a corresponding field weakening is permissible without excessive sparking. For example, a motor intended for 40 amperes with full field may carry 30 amperes with its field weakened to give about 20 per cent. increase in speed.

These conditions apply to other commutator machines in which there is any considerable variation in field strength, such as a booster for charging storage batteries, its voltage being regulated between wide

limits by means of its field rheostat. The general fact is that the allowable current is reduced as the field is weakened.

Further information on this subject may be found under "Sparking," Cause 9; "Speed Too High or Low," "Motor Stops or Fails to Start," and "Dynamo Fails to Generate."

Cause 9.—Unequal strength of magnetic poles. This might be regarded as a special case of the preceding cause of sparking—"weak magnetic field"—but is sufficiently important and different in principle to warrant separate consideration.

Symptom.—With bipolar generators or motors, one pole carries the same flux as the other, there being only one magnetic circuit. The distribution may differ, owing to different pole shape or magnetic leakage, but is not likely to produce sparking or other trouble. In a machine having more than two poles the flux in one may be much greater or less than that in each of the others. Multipolar armature windings for generators or motors (except railway motors as stated later) are usually of the parallel or multiple-circuit type which offer as many paths for the current as there are poles. With this arrangement, the fluxes through the several poles must be exactly equal in order that equal e.m.f. shall be generated in the corresponding portions of the armature. If one pole were weaker than the others a back current would flow through that part of the armature winding even with the external circuit open, all of the positive brushes and all the negative brushes being respectively connected together so that the paths of the armature winding act in parallel.

A difference in e.m.f. of only 1 or 2 per cent. might cause the full armature current to flow, although there may be no external current. With greater differences in flux and e.m.f. this internal current may rise above the normal value and cause sparking. Fortunately this trouble tends to counteract itself, because the back current strengthens a weak pole and current in the proper direction weakens a strong one. Nevertheless, differences of this kind often exist and should be looked for when sparking occurs with little or no external current, especially in a new machine. To detect them, the brushes are disconnected from each other or when this is difficult they are all raised from the commutator and two small temporary brushes of copper leaf or wire are applied successively in the usual brush positions. These brushes being connected to a voltmeter, any difference in e.m.f. between the different portions of the armature may be determined.

Remedy.—This difference is usually due to the fact that the armature is closer to one or more poles than to the others, tending to give greater flux and e.m.f. at the former. In such a case it is usually perceptible to the eye or found by measuring with a wedge that the armature is not properly centered. This condition may be corrected by slightly shifting the bearings, but with most machines, especially when direct-connected, it is preferable to shift the field magnet. Ordinarily, this adjustment can be made by putting in or taking out sheets of iron between the lugs or feet on the field ring and the bed plate. Some machines are built with several thin sheets of iron interposed between each field core and the ring, so that adjustment of the individual poles can readily be made at any time.

When the armature gets out of center, owing to considerable wear in the bearings, the proper remedy is to renew the latter. To anticipate slight wear the armature is sometimes adjusted a little nearer the upper poles. Another way to remedy this trouble is to vary the number of turns of wire in the several field coils until the same flux is produced by each. Of course, this trouble cannot occur in a bipolar machine, not only because the fluxes are equal for the two poles, as already noted, but also because it is not possible for one path through the armature to have less e.m.f. and act as a short-circuit for the other. For the same reason, a multipolar armature with series or two-circuit winding is free from this trouble. This type of winding, however, is not generally used, except for railway motors.

Cause 10.—Vibration of the machine.

Symptom.—Considerable vibration is felt when the hand or a stick held in the hand is placed upon the machine, and the sparking decreases when the vibration is reduced. Vibration of the brushes, due to a rough or sticky commutator, is hardly sufficient to cause the whole machine to vibrate, nevertheless, reference may be made to "Sparking," Causes 3 and 4.

Remedy.—The vibration is usually due to an imperfectly balanced armature or pulley (see "Noise," Cause 1), "knocking," due to looseness of the engine parts, a bad belt (see "Noise," Cause 6), or to unsteady foundations, and the remedies for these troubles should be applied.

Any considerable vibration is likely to produce sparking, of which it is a common cause. This sparking may be reduced by increasing the pressure of the brushes on the commutator, but the vibration should be stopped by the remedies referred to above.

Iowa Telephone Association.—The Iowa Telephone Association will hold its ninth annual meeting at the Chamberlain Hotel, Des Moines, Ia., March 14, 15 and 16. The association will hold its session in one of the private dining rooms on the parlor floor. Exhibits will be made by telephone supply men and manufacturers on the fourth floor of the hotel. The occasion is expected to be a most enjoyable one, and an elaborate program is being prepared. The banquet will be held on Wednesday evening, March 15. Mr. C. C. Deering, Boone, Iowa, is the secretary of the association.

Principles of Electrical Apparatus

THE STATOR OF AN INDUCTION MOTOR.

The stationary part, or stator, of an induction motor combines the functions of a field magnet with some of those of an armature. As its windings and the current in them produce the magnetic flux which causes the rotor to revolve, it is a field magnet, but in all other repects it behaves precisely as though it were a stationary armature within which a field magnet is being revolved. On this account, instead of being provided with physical poles of the ordinary type the core is made exactly as that of an external armature would be made, except that the slots are larger, as illustrated by Fig. 1. The core is laminated, as the sectional view, Fig. 2, indicates, for precisely the reasons that armature and transformer cores are laminated.

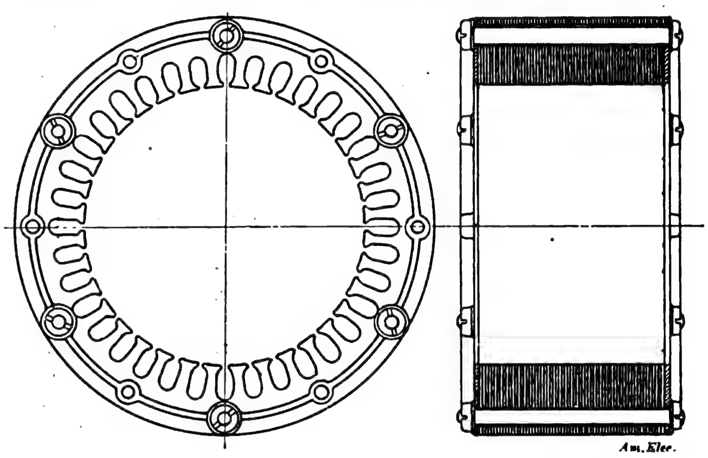

FIG. 1.—STATOR CORE OF AN INDUCTION MOTOR.—FIG. 2.

There are several other reasons why the form universally employed for the stator is preferable to the more familiar type of field magnet with projecting poles; it will perhaps suffice to give one. The windings of the rotor and those of the stator must approach as nearly as possible the conditions of the primary and secondary windings of a transformer, because their inductive relations are the same—the flux induced by the primary (stator) winding must be enclosed by the loops of the secondary (rotor) conductors to the greatest possible extent in order to give the machine good efficiency and a reasonable power factor. If the two

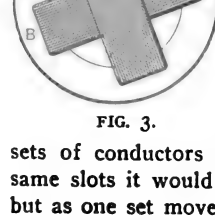

FIG. 3.

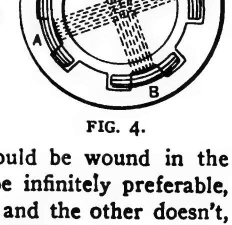

FIG. 4.

sets of conductors could be wound in the same slots it would be infinitely preferable, but as one set moves and the other doesn't, this is obviously impossible.

In order to simplify the explanation of the combined effect of two sets of field

windings supplied with two currents differing in phase, the stator of an elementary induction motor was described in a previous article as having the coils mounted as indicated in Fig. 3, which is repeated from that article for convenient reference.

Am. Elec.

FIG. 5.—BIPOLAR STATOR.

In practice, even if bipolar motors were used, the coils would not be thus mounted. Referring to Fig. 4, also repeated from the article referred to, it will be evident that the coils, A and B, can be maintained in their present positions in the stator core by simply parting the end portions and bending them around against the ends of the core, as indicated in Fig. 5, and this is what would be done in an actual machine.

As the rotating magnetic field sweeps around it is "cut" by the wires in the stator slots precisely as the wires of an alternator armature cut the lines of force of the magnetic field, and this "cutting" induces in each winding, A and B, an e.m.f. which is equal to $4.44\ \Phi\ f\ N \div 100{,}000{,}000$, in which Φ is the number of lines in the rotating magnetic field, f is the frequency of the magnetic current, and consequently the number of revolutions per second of the magnetic field (in a bipolar motor); and N is the number of complete turns in each winding. This is precisely analagous to the action of a direct-current dynamo, in which the e.m.f. generated in the armature winding is equal to $\Phi\ f\ w \div 100{,}000{,}000$. Most of the apparent discrepancy between this formula and the formula given above is due to the facts that here w, representing the wires on the armature, is used instead of N, the number of turns, and that the wires are not all in series on the armature, whereas they are so on the stator. If we consider the turns, N', on a drum armature instead of the wires, the formula becomes $E = 2\ \Phi\ f\ N' \div 100{,}000{,}000$; and if we only consider those turns, N'', that are in series with each other, it becomes

$$E = 4\ \Phi\ f\ N'' \div 100{,}000{,}000.$$

The only difference between this and the induction motor formula is that the constant is 4 instead of 4.44; the reason for this is that the wires on the stator of an induction motor are not so distributed as those on the direct-current armature, and consequently the difference in the rates at which the different wires of the winding are cutting lines of force at any given instant is much less and the total e.m.f. considerably higher. When the stator winding is more distributed, as the multiplicity of slots in Fig. 1 truthfully indicates that it is in practice, the e.m.f. induced in the winding by the rotating flux is less than the formula makes it, the correction usually being made by retaining the constant 4.44, which is fundamental, and introducing another constant representing what is usually termed the coil-breadth factor. In most two-phase motors this second constant is between 0.91 and 0.92, which is equivalent to reducing the constant 4.44 (which is a shortening of the more accurate figure, 4.442853) to 4, making the alternating current formula agree with that for a direct-current armature.

The e.m.f. induced in the stator windings by the magnetic flux opposes the e.m.f. which is applied to the stator terminals, and furnishes the counter e.m.f. of the machine. As the flux remains constant it would seem that the counter e.m.f. would be constant, which would not be logical. The reaction of the rotor upon the field, however, causes the counter e.m.f. to vary with the load. This will be discussed in a future article.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Motor-Driven Machine Tools.

Last month's article on motors for machine tools, by Mr. Hanchett, was read with much interest and profit. However, his remarks on field control motors do not include a late type of field control which has not the disadvantage he mentions. There are motors of this type which have a range of speed of 2 to 1, without any waste of power in resistance, give full power at all speeds, do not spark, and have the advantage of operating on a two-wire system. Of all the methods of speed control the armature-resistance method is the poorest, and the multi-voltage system, where voltages as low as 50 volts are used, is almost as bad. At low voltages, an increase in power causes excessive drop in the lines. As the work done by machine tools is usually governed by the heat at the point of the tools, it follows that at slow speeds—with heavy cuts—more power can be used to advantage. Then it is an advantage to use a slow-speed motor, but at times higher cutting speeds are desired, and as the desire is to do the work as fast as possible, the same power is sometimes required at all speeds, that is, at all times, to work the machine tool to its limit. It is understood that a shunt motor is referred to. Now, if a motor will exert one horse-power at 2300 r.p.m. and also at 1200 r.p.m., it is certainly an advantage to use it, as it will be no larger than a standard motor at 1200 r.p.m. Such a motor, with field control, holds a constant speed at the point set, which is surely to be desired, since any change in the load would cause other types of motors to speed up or slow down. We are all familiar with the action of a series motor on variable loads, and this is the way (though not to the same extent) that a motor controlled by an armature resistance would act on its low speeds, taking a heavy cut. A resistance-controlled motor, if set at the right speed for a cut, will run at a lower speed when cutting; consequently, after the cut is started the speed must be increased. There are none of these drawbacks when using the latest types of field-control motors (I do not refer to electrical field control, but magnetic). Mr. Hanchett's formulæ condemn the use of armature-resistance control, as they show that for a lathe of about 18 ins. swing a 6-h.p. motor would be used, while with field control but one horse-power is necessary. Putting 6-h.p. motors on 18-in. lathes would make the cost of the tools rather high, and the article if read by inexperienced purchasers or tool makers might prevent the use of motor drive for tools. I do not wish to start a controversy, but only desire to know what is best and to increase my knowledge. If I am wrong, I will be glad to learn why.

JAMES E. MCHUGH.

Pleasant Ridge, Ohio.

Brush Arc Dynamo Commutators.

I have had several years' experience with the old Brush direct-current arc machine, and I find that there are a great many of these dynamos still in use throughout the country. Most of the difficulty with these troublesome old machines is with the commutators, and there have been more than a dozen "patent" commutators gotten out, almost all of which are worse than useless. I will try to describe a kind of commutator that I have been making and using for two years, not because it is ideal, but because it serves the purpose better than anything else I have been able to find. It is not unlike the original Brush commutator, for the electrical principle is exactly the same, and I use the same kind of segments and wood blocks. The Brush commutator consisted of a wooden hub on which was laid a layer of paper, then the brass segments, and finally the copper segments and wood blocks. The lead-in wires passed from the brass segments down through the paper layer, under which they ran out to the end of the commutator. Some of the objections to this arrangement were that the paper did not furnish a solid support for the segments and wood blocks, and the holes made by the screws soon became worn beyond repair. To make my commutator I take a piece of well-seasoned maple and turn up a hub of sufficient diameter, so that I do not need any paper at all under the segments. On the surface of this I mark out the exact positions in which I want the wires to lay. Then while the work is still between the centers of a small lathe I place a special tool in the rest and cut slots for the wires about 3/8 inch deep by drawing the carriage back and forth by hand. Then the wires are laid in these slots, leaving one end of each sticking up just where it is to be soldered to its segment. This done, I glue in strips of wood to fill up the slots and keep the wires down in the slots. When the glue is dry I boil the whole in paraffine; this helps the insulation and stops all further

shrinking and swelling. Finally, I mount the segments and wood blocks in the usual way, and have a good, solid, true commutator. I connect the commutator to the armature leads by means of small screw-connectors instead of soldering them. Any engineer can make this commutator easily and quickly himself, and it is so cheap that one can always be kept on hand so that when one wears out or becomes damaged it can be pulled off and replaced by this one in a few minutes.

ALBERT G. FULTON.

Oconto, Wis.

Care of Storage Batteries.

Referring to Mr. R. P. Bryan's letter on storage batteries, in the January number of your paper, would say that I charge them to 2.5 or 2.6 volts per cell, with the specific gravity at 1200 degs. to 1205 degs., according to the temperature of the battery room, for as the temperature rises 10 degs. Fahr., the specific gravity will rise 3 degs., and *vice versa* when it lowers. I have found in my experience that the specific gravity is just as important as the voltage, if not more so, as the latter when the battery is fully charged, before disconnecting the charging circuit, may rise to 2.5 volts per cell, and yet the specific gravity may not be up to what it should be; but when the specific gravity rises to 1200 degs. or 1205 degs. the voltage will at all times be normal, except when a short-circuit in the battery comes on. The average specific gravity drops during discharge and the number of points lost should be regained on the charge; the voltage will then be correct if one always takes into consideration the drop and rise in the temperature of the battery room, as stated before.

ERNEST F. HARTWELL.

Hoboken, N. J.

Noticing a question raised by R. P. Bryan in your January issue on storage batteries, I submit the following views on the subject, thinking they may be of some interest to Mr. Bryan in handling his plant. The fall of e.m.f. of a storage battery after the battery has been taken off the charging circuit always occurs. The battery will generally come back to the normal of 2 volts per cell and hold that almost to within 80 per cent. of the charging capacity, providing it is of a good standard make. I should advise Mr. Bryan to accustom himself to the use of an acidometer, generally called hydrometer, to test the density of his electrolyte and not go altogether by the voltmeter. Take, for instance, a battery of cells used for lighting purposes, which has by overdischarging formed a thin coat of sulphate of lead on the plates; after being on the charging circuit for the time required for a practical charge, the battery will come to a boil, or become cloudy, and perhaps the voltage is up a point above 2 volts per cell. It will be found on taking this battery off the charging circuit that its storage capacity is not by any means up to standard. The cause is the sulphate on the face of the active material. The slower charging process for destroying sulphate is recommended, and I have found it successful if properly applied. The condition of a battery may usually be noted by a look at the edges of the plates, both negative and positive, when one has become accustomed to the various changes of color during the process of charging. If the positive plate shows a dark seal brown coating and the paste or active material is easily removed by rubbing a finger tip over it, I will vouch for the plate being in a good condition to take its normal charge. The negative plate should be a clear slate gray color, a shade dark. The acidometer will detect sulphate by not registering as much as before the sulphate formed. My advice is not to discharge a battery further than to cause a fall of over 20 degs. ordinarily, and never over 25 degs., in the specific gravity of the electrolyte. Beyond this point, a number of things happen if discharging is continued, such as sulphating both plates, hardening the grids and making them liable to buckle and break, hardening the active material and causing it to shrink and possibly fall out of the grids, etc.

H. N. SNYDER.

Santa Paula, Cal.

Unequal Heating of Commutator Brushes.

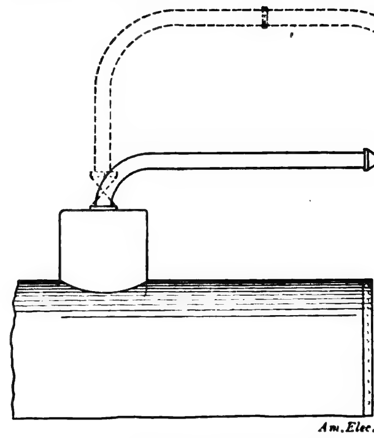
On page 99 of the February issue of the AMERICAN ELECTRICIAN, M. I. H. asks why the negative brushes of a rotary converter become overheated sooner than the positive brushes with an overload. There is a very good reason for it, for while a brush is negative with reference to the circuit, it is positive with reference to the commutator. In other words, the current travels from the negative brush to the commutator and from the commutator to the positive brush. It is a well-known fact that when two electrodes are placed in a direct-current circuit, and especially when the electrodes are of carbon, the positive electrode will heat a great deal more than the negative. This is demonstrated in the arc lamp. While the brush may not be actually flashing yet, on overload the sparking under the face is enough to decidedly overheat the negative brush. At the positive brush, however, the positive electrode is the connector, which is a much better conductor of heat, and having a much greater radiating surface it leaves the positive brushes comparatively cool.

E. C. MEILLORET.

Woodhaven Junction, N. Y.

Mr. Walthall's Boiler Connections.

In the January issue of the AMERICAN ELECTRICIAN, Mr. M. E. Walthall asked for the opinions of others on his boiler connections. According to my notions, both of his ideas are at fault, if the boiler is in a battery and steam is used from the other boilers through this same header. The connection shown in the solid lines does not allow for expansion of the header, which is liable to break the fittings at the valve. The piping should also drain toward the boiler from the valve and the header should drain toward the engine. The arrangement shown in dotted lines allows for expansion and also



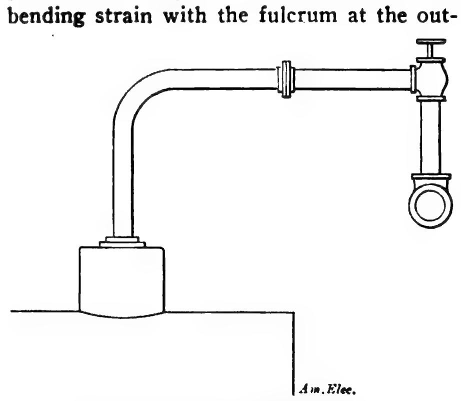
BOILER CONNECTIONS.

allows water to collect over the valve in the pipe. I should prefer the arrangement shown by the accompanying sketch. By placing the angle valve over the header and draining the piping as stated before, it does not allow any water to collect in the connections, and also allows for expansion.

M. C. ST. JOHN.

Rayne, La.

Referring to Mr. Walthall's question on boiler connections in your January issue, to which Mr. Brand and Mr. Trotman replied last month, I cannot agree with the solution offered by either. The piping as shown by the solid lines is clearly wrong in that no provision is made for expansion, and the stress due to this cause will come against the header springing it sideways, and upon the connections at the dome. If the header is properly braced so as to be absolutely rigid in all transverse directions, then the elongation must take place toward the boiler and if the bend is sufficiently stiff might be stressed beyond its elastic limit. I cannot agree with Mr. Brand that the strain at this point is shearing, but consider it rather a bending strain with the fulcrum at the out-



MR. ST. JOHN'S ARRANGEMENT.

side of the curve of the pipe near the dome and the probable point of rupture on the side toward the header.

The connection, as shown by the dotted line, is the more desirable since, owing to the considerable length of the vertical pipes and the flexibility of the bends, it will have sufficient spring to take care of its own ex-

pansion and the effect upon the connections will be harmless.

The introduction of other bends or loops would be needless as far as expansion is concerned, and would only tend to obstruct the flow of steam. There should be a valve at both the boiler and header, and if the boiler is operated within the limits of New York City this will be required. This will eliminate any condensation taking place when the boiler is out of commission.

Long sweep bends in boiler delivery, engine supply pipes, etc., have become standard practice, and are to be found in all the large modern power stations.

LOUIS C. REYNOLDS.

New York.

Referring to the question raised by M. E. Walthall in the January number regarding boiler connections with steam mains, I should say, by all means, that the pipe shown in the dotted lines is the best. If there is anything in steam piping that must be allowed for it is expansion, and if it isn't considered it soon makes itself known. Let anyone bend two pieces of wire, one in the shape of the curved pipe and one the direct pipe, then see how much easier the bent wire will give when the ends are pressed toward each other.

I have charge of a battery of four boilers which were connected to the main in practically the same way as the lower connection in the illustration, and they were always a source of trouble.. Almost every time a boiler was shut down the flanges had to be repacked. One gave so much trouble that we decided to put in a long bend connection very similar to the one shown by the dotted lines, except that a gate valve was inserted near the flanged joint in the highest part of the pipe. That prevented any water from collecting in the pipe.

Since putting in this new pipe we have had no trouble with it whatever, and we will probably equip the other boilers in the same way.

The stress due to pipe expansion was so great on this particular boiler that it strained the nozzle on the boiler, and came very near fracturing the ell in the piping.

If it is thought advisable to have two valves one should be put at either end and suitable drains placed in the piping to let out the water which collects in them. In starting a fire in an idle boiler under such conditions one valve should be opened, and when ready to connect with other boilers the water above the valve should be drawn off, otherwise disastrous water hammer is likely to occur.

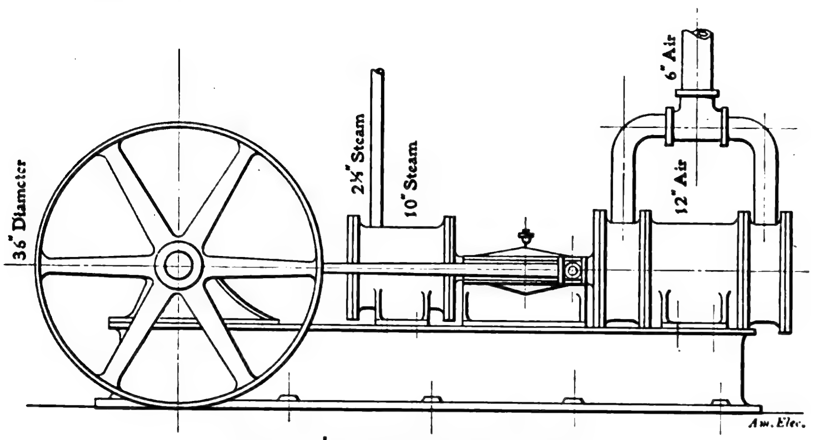
Doubling the Capacity of a Vacuum Pump.

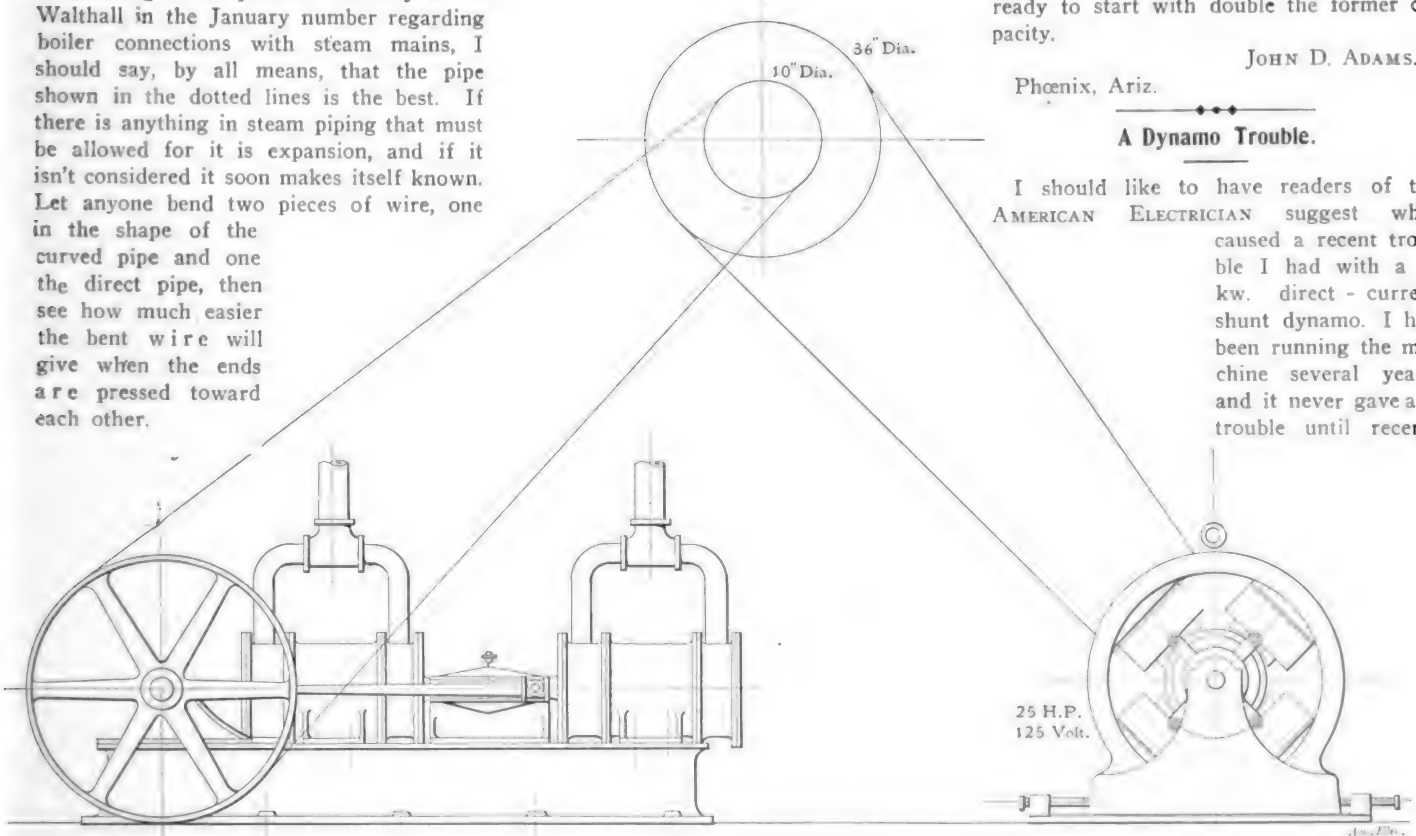


MR. ADAMS' ORIGINAL VACUUM PUMP.

We had a 10 in. by 12 in. by 12 in. stroke, straight line steam-driven, vacuum pump maintaining a vacuum of 15 in. according to the mercury gauge. It was necessary to have a pump of greater capacity, and as we had a couple of small pressure pumps for the sprinkler system alarm in the same room, we decided to replace the steam drive with its 100 ft. of piping, by a belt driven machine, and use a motor to operate the three pumps. Instead of buying a new pump, we had our own machine shop turn out a duplicate of the present air cylinder with which to replace the steam cylinder and drive both by a belt on the flywheel. The new arrangement will be evident by referring to the sketch herewith, and proved very desirable in every way. The change as made in our own shop was much cheaper than a new machine, and as for the electric drive it gave less trouble than the 100-ft. steam line, and also enabled us to handle the small pressure pumps advantageously. Everything was in readiness, so that when the pump was shut down Saturday noon, the work of making the change was commenced and by Monday morning everything was ready to start with double the former capacity.

JOHN D. ADAMS.

Phœnix, Ariz.



MR. ADAMS' VACUUM PUMP, HAVING DOUBLE THE CAPACITY OF THE ORIGINAL.

A Dynamo Trouble.

I should like to have readers of the AMERICAN ELECTRICIAN suggest what caused a recent trouble I had with a 2-kw. direct-current shunt dynamo. I had been running the machine several years, and it never gave any trouble until recently, when two leads became short-circuited in the armature. The armature was taken out and the trouble repaired, which only consisted of a single wire being burned close to where it is soldered to the commutator.

The armature was replaced and the machine started up, but it would not pick up. We tried every way possible to make it do so with the same condition under which it had run before, but without success. We finally discovered that the residual magnetism tended to excite the fields in the wrong direction. We, of course, reversed

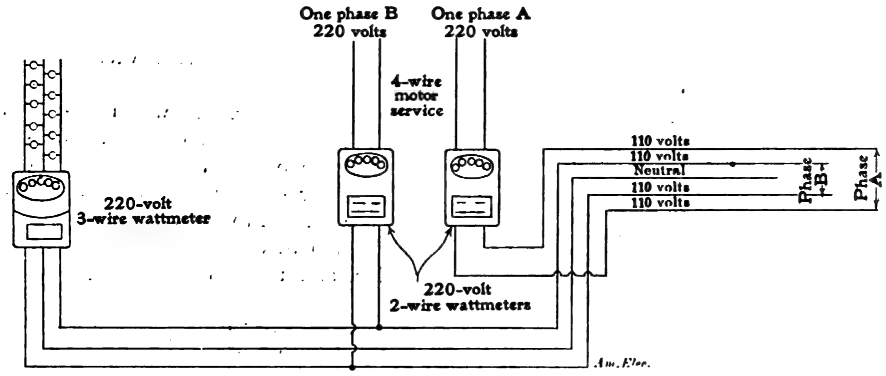


FIG. 1.—DIAGRAM OF SERVICE WIRES SUPPLYING CURRENT FOR LIGHT AND POWER.

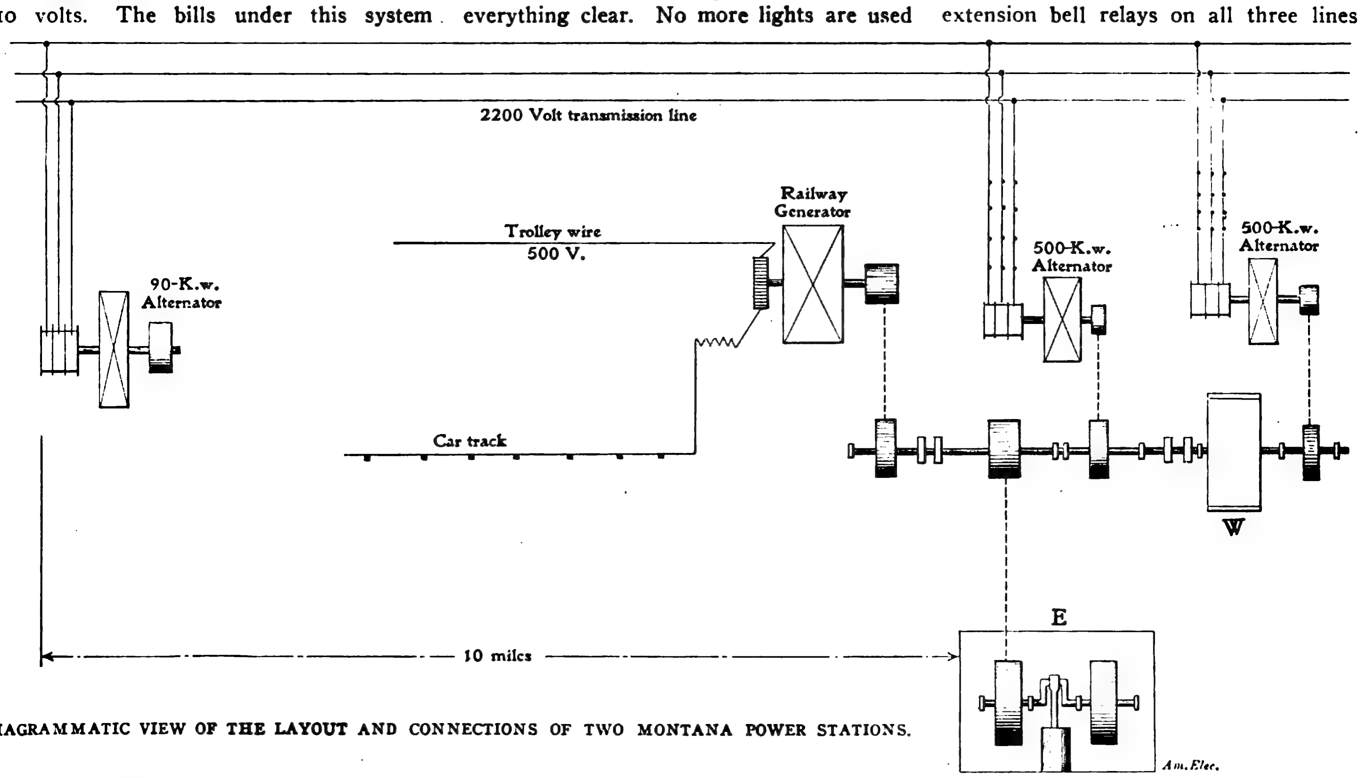
the field leads and the machine immediately picked up. Now, why was it necessary to reverse the fields after the machine had been running for years without trouble? The armature connections were not changed, neither was the position of the brushes altered.

J. T. Bannister.

Richmond, Va.

Excessive Current Consumption.

I would like to know what would cause an increase in the bills for electricity consumed in the following case: The lighting system installed eight years ago was a two-wire, single-phase, alternating current of 110 volts. The bills under this system



DIAGRAMMATIC VIEW OF THE LAYOUT AND CONNECTIONS OF TWO MONTANA POWER STATIONS.

ranged from $35 to $40 per month, using 16-c.p. lamps. About ten months ago the lamps were changed to 8-c.p., 3½-watt lamps, and the bills amounted to $15 and $17, which was exactly what was looked for by the consumer. This continued for about six months, when the consumer decided to have a 2-h.p. motor installed. The company furnishing the current decided to have this motor two-phase, four-wire, 220 volts, and in running in the service wires for this motor they used five wires, and decided to change the old lighting system from a two to a three-wire system. On the day this change was made the reading was taken for the light consumed during the month and the bill amounted to about $15. The month following this change of wiring the bill amounted to $32, and since then is anywhere from $32 to $40. The motor being on a separate meter, for which a separate bill is rendered, the above amounts are for light only. The consumer naturally made strenuous objections to this increase, and the company claims to have made every known test, and not finding anything wrong, are still claiming payment at the increased rate. The bills, however, remain unpaid. I am at a loss to account for the increase. I have made tests for grounds, and find everything clear. No more lights are used than before, and these are not used any longer than when the bills ranged from $15 to $17. I would like very much to get a solution of this problem through your valuable paper. Fig. 1 is a diagram of the service wires which supply the motor and lights.

J. C. Vogel.

Philadelphia, Pa.

A Question in Station Operation.

The enclosed diagram shows roughly the layout and connections of our two power stations. At the main station there are two 500-kw. alternators, driven normally by the water-wheel, *W*, the engine, *E*, being used only in emergencies. The pulleys on the line-shaft of the water-whel are provided with clutches. The alternator in the distant station is a 90-kw. machine, but it is impossible to make it take more than 20 to 22 amperes without dragging on the machines at the main station. Also, when a heavy load comes on the railway generator at the main station, it throws an extra load on the distant alternator. The exciter of this latter machine is speeded at only 1900 r.p.m., although the speed on the name-plate is 2200. I will appreciate it if readers of this paper will express their opinions as to the causes and remedies of the troubles mentioned.

L. R. Clarke.

Bozeman, Mont.

Problem in Telephone Connections.

I would like to submit a small problem to readers of this paper. We have three telephone lines centering at one place, with a single telephone set which may be connected to any one of the three lines, and extension bell relays on all three lines to receive calls. The lines are all metallic circuit, the instrument the ordinary bridging type. It is desired to arrange standard knife-bade switches so that when any two of the lines are connected together the third

may be independently called or answered.

Laurence P. Brode.

Colton, Cal.

Information Desired.

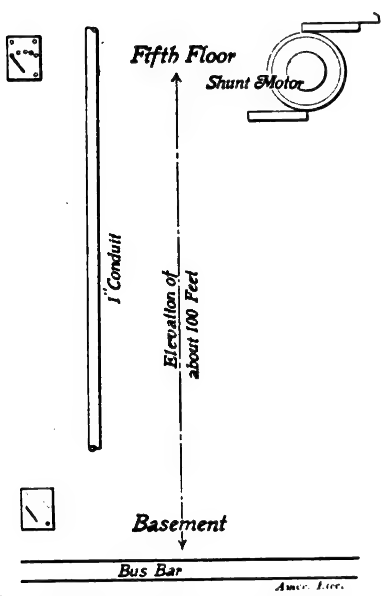
Can any of the American Electrician readers instruct me as to the proper winding for the S. K. C. ½-h.p. alternating-current motor for 100 volts and 66 cycles? The machine has four poles, and the armature 56 slots.

L. G. Esther.

Halifax, N. S.

Problem in Motor Connections.

I have a motor problem which is rather puzzling, and I think it will be of interest to your readers. A 7½-h.p. direct-current motor is to run on a 220-volt circuit. One starting box is in the basement on the



PROBLEM IN MOTOR CONNECTIONS.

switchboard; the other is on the fifth floor with the motor. The motor is to be started from either place or stopped from either place. The wires that go to the starting box and motor are to be run through a 1-in. conduit. The total length of conduit is about 200 ft., but the elevation to the motor is 100 ft. It does not make any difference what kind of apparatus is used, so long as the work will pass inspection. The machine is a shunt-wound motor. It might be well to say that three No. 6 or four No. 8 wires can be run through the pipe. The accompanying sketch shows the apparatus located in the proper places.

Harold M. Wolf.

Cleveland, Ohio.

Sleet on Electric Line Wires.

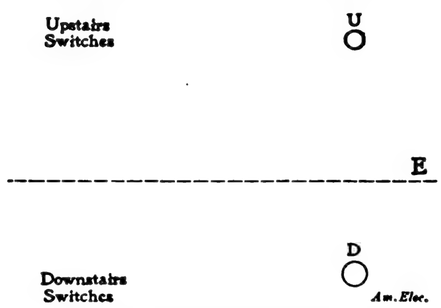
The statement is often made that sleet does not form on bare, high-tension wires, and in that connection I would like to say that as this letter is being written (February 8) it is sleeting, and our 12,000-volt, three-phase transmission line is covered with ice ½ inch thick—with current on the wires. I should like to ask through this department of the American Electrician, whether any of its readers ever saw sleet, snow or ice on a 50,000 or 60,000-volt transmission line?

F. P. Catchings.

Gainesville, Ga.

Problem in Switch Connections.

Perhaps the accompanying diagram will afford some mental exercise to readers of the American Electrician. The diagram represents an incandescent lamp, *U*, in the upper hall of a residence, another lamp, *D*, in the lower hall and the main entrance for the wiring, *E*. The problem is to connect



PROBLEM IN SWITCH CONNECTIONS.

the two lamps with switches located in the two halls in such manner that the lamps can be put in circuit in parallel from either one of the switch stations, or put in series at the upstairs switch station; also, either lamp can be extinguished from either switch, leaving the other lamp burning. Only standard switches and the least practical quantity of materials must be used. Summing up, the following results must be obtainable:

At either switch station, either one or both lamps may be lighted at full candle-power and extinguished, regardless of the condition of the switches at the other station, except that when in series, they can only be extinguished and lighted from downstairs—not controlled separately.

At the upstairs station, in addition, the lamps may be connected in series for night service, regardless of the positions of the switches downstairs.

B. F. M. Weaver.

Wilmington, Del.

Mr. Westervelt's Insulation Resistance.

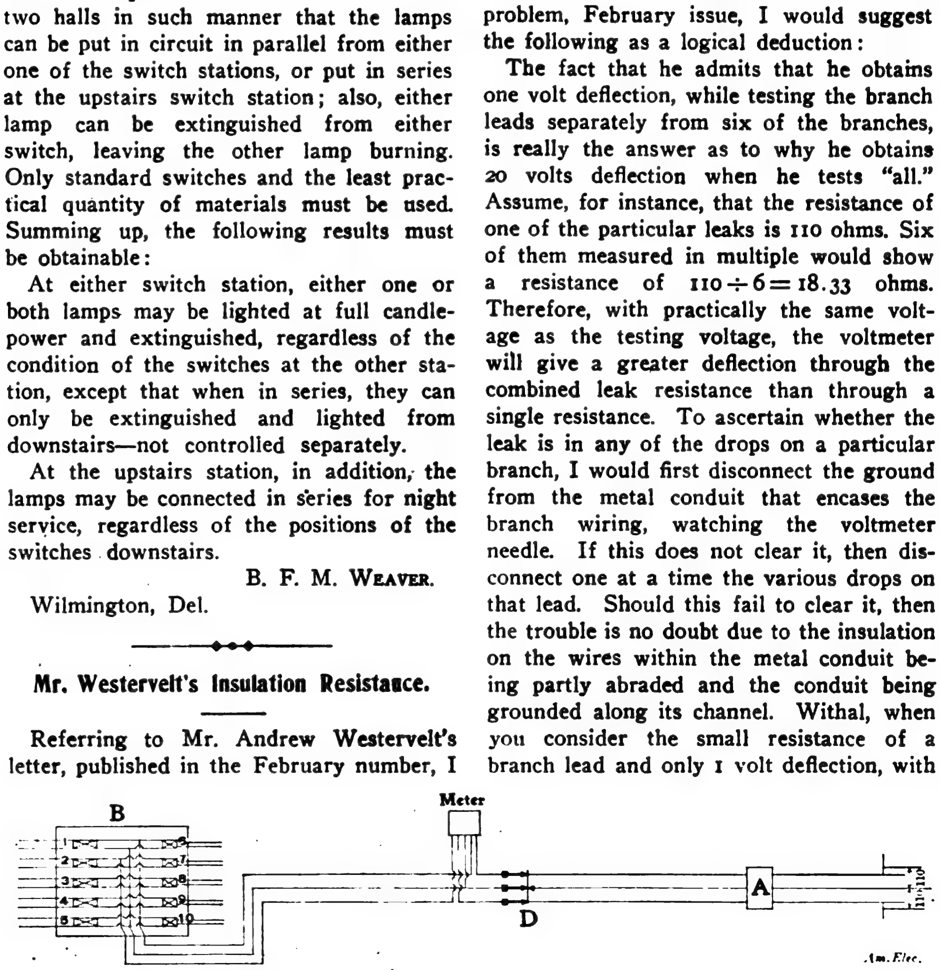
Referring to Mr. Andrew Westervelt's letter, published in the February number, I should think his trouble due either to dampness in the fittings and switches, or possibly in the wire. I would say it was what I have frequently found, grounds due to dampness in the fittings which were mounted on the metal outlets of the conduit, but as he says that in each of the six circuits he only had one volt to each, and yet 20 volts in the total branches, it puts the trouble in a different light. Finding the resistance of each of the six circuits by the formula,

$$R = r\left(\frac{E}{v} - 1\right),$$

in which r is the resistance of the voltmeter; E the line voltage, and v the voltage to ground indicated by the meter, and then finding the joint resistance of the six circuits, would not give a total of 20 volts leack. I think it possible that when Mr. Westervelt took the reading of the separate branches he obtained a ground reading of one volt, but in taking the reading of the fuse block he got a reading showing that there was a shunt path for the outside line voltage of 220 volts, which excluded the ground. I do not think he had the meters connected as shown, for he would have had a high reading on the side on which the meter armature was shunted.

W. A. Loveland.

Philadelphia, Pa.



MR. WESTERVELT'S INSULATION RESISTANCE PROBLEM.

Referring to Mr. Westervelt's insulation problem, February issue, I would suggest the following as a logical deduction:

The fact that he admits that he obtains one volt deflection, while testing the branch leads separately from six of the branches, is really the answer as to why he obtains 20 volts deflection when he tests "all." Assume, for instance, that the resistance of one of the particular leaks is 110 ohms. Six of them measured in multiple would show a resistance of $110 \div 6 = 18.33$ ohms. Therefore, with practically the same voltage as the testing voltage, the voltmeter will give a greater deflection through the combined leak resistance than through a single resistance. To ascertain whether the leak is in any of the drops on a particular branch, I would first disconnect the ground from the metal conduit that encases the branch wiring, watching the voltmeter needle. If this does not clear it, then disconnect one at a time the various drops on that lead. Should this fail to clear it, then the trouble is no doubt due to the insulation on the wires within the metal conduit being partly abraded and the conduit being grounded along its channel. Withal, when you consider the small resistance of a branch lead and only 1 volt deflection, with 110 volts, I doubt very seriously the necessity for giving the wiring much concern.

James B. Dillon.

Louisville, Ky.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

Would it be advisable to use a three-phase induction motor for operating an elevator of 6000 lbs. capacity, the motor to be supplied from a 230-volt monocyclic circuit? The motor would be a 25-h.p. machine. B. A. S.

No; either get a monocyclic motor or change your supply to symmetrical polyphase.

A home-made arc lamp, operated on a 100-volt, alternating-current circuit in series with resistance coils, works all right, but a short time after starting up it begins to hum. What is probably the cause? R. L. C.

Some of the mechanism loosens up from expansion due to the warmth of the lamp; any loose joints, screws, etc., in an alternating-current lamp mechanism will hum.

In thawing out frozen water pipes by electricity, does not the current spread into the surrounding earth between the ends of the pipe, and if so, how is the middle part of the pipe thawed out? A. E. G.

Some current may pass through the adjacent earth, but that does not prevent most of it from passing through the iron pipe, which is of much lower resistance.

How can a single-phase, four-pole induction motor be changed from 100 volts and 125 cycles to 200 volts and 50 cycles without changing its horse-power? D. L. F.

It can't be done, but if the motor be rewound for two poles with twice the original total number of turns in the stator winding, it will work moderately well at almost the original power.

What is the best way to utilize 2080-volt transformers on a 2300-volt circuit? (2) Can I use transformers wound for 2080-volt primary e.m.f. and 230-volts secondary on a 2300-volt primary circuit and get 220 volts at the secondary terminals? W. J. N.

Use them as though they were intended for 2300 volts. The secondary e.m.f., however, will be somewhat higher than the rated e.m.f. (2) No; the secondary e.m.f. will be 254 volts.

What is the best insulator to use on a 2200-volt line in a damp climate? (2) Is there any compound with which the wire could be coated at the points where the wire is attached to the insulators for decreasing the leakage in wet weather? (3) What is a cycle? G. H. B.

A glass or porcelain insulator of the multi-petticoat type, made for the conditions mentioned. (2) No; the entire wire is coated with a good compound by the manufacturer, if it is a standard brand. (3) We have defined the word many times in the past year or two. See pages 411 and 424, August, 1904.

Is it good practice to use rubber-covered, lead-sheathed conductors for underground work? (2) In running a number of underground circuits parallel with each other, would it be better to put all the positive conductors in one conduit and the negatives in another, or to put in each conduit both conductors of each circuit contained therein? J. M. D.

Yes; but it is rather expensive. (2) If there is no possibility of ever using alternating current, one method is as good as the other electrically; but where alternating current is used or may be used in future, all the conductors of any one circuit must go in the same tube.

What is the best way to equip a house 50 x 65 feet with lightning rods? (2) What material should be used in the rods? (3) Should they be insulated from the house? F. E. B.

The best way to attempt protection from lightning is to erect four or five poles about 25 feet from the house, equidistant from each other, and so located that a line drawn from pole to pole successively will encircle the house. Put an individual rod on each pole. The rod tips should be considerably higher than the house—say 15 to 20 feet above its highest point. If, however, you put the rods on the house, put one at the apex of each gable, or, if a mansard roof, one at each corner. Use individual grounds for the rods. (2) Copper. (3) Preferably.

What is the best method of testing out the plan of armature-to-commutator connections of a direct-current dynamo or motor? B. C. H.

Disconnect one lead from one coil; connect one terminal of a voltmeter to the disconnected lead and the other terminal to a circuit of appropriate voltage; disconnect two other coil leads, each about one-third of the commutator circumference away from the first one, and leave them free; with a lead from the other side of the supply circuit, test the commutator bars until one is reached which causes the voltmeter to give an indication equal to the voltage of the circuit. This last commutator bar will be connected to the other lead of the coil which is connected to one post of the voltmeter, and the distance apart of the two bars to which this coil is connected will be the basis of the winding plan.

What is the correct arrangement of leads and instruments in connecting a compound-wound direct-current dynamo to the bus-bars? (2) What simple solution can be used for oxidizing copper-plated metal? A. W. R.

The lead from the free terminal of the series winding should go directly to one pole of the main switch; the lead from the junction of the series winding and brush connection goes to the equalizer switch; the remaining lead, from the free brush terminal, should go first to the circuit-breaker, then to the individual ammeter and finally to the main switch. It is usually more convenient mechanically to carry the last-mentioned circuit from the circuit-breaker to the main switch, and put the ammeter between the switch and the bus-bars; it is of small importance which sequence is observed, but logically the main switch should be last in the chain from the machine to the bus-bars. (2) Dip the object to be oxidized in the following solution: Liver of sulphur, 3 ozs.; ammonia, 1 oz.; water, 1 gallon.

What potential will be required to run a series-wound dynamo as a motor at full speed, the dynamo being capable of supplying 20 lamps of 50 volts each? (2) Why does not a vacuum show gauge readings corresponding with the readings of a steam gauge under similar conditions? G. P.

About 1000 volts, that being the e.m.f. of the machine when used as a dynamo. (2) Because a vacuum is absence of pressure. A vacuum gauge will vary oppositely to the variations of a steam gauge pointer under similarly varying conditions; thus, a rise in steam pressure will cause the gauge to give a higher reading, but an increase in the pressure within a vacuum chamber will lower the reading of the vacuum gauge, which registers the difference between the internal pressure and the atmospheric pressure. If a pressure gauge and a vacuum gauge be connected side by side to a vacuum chamber, any variation in the degree of vacuum will cause the two pointers to move in opposite directions.

In this department of the January number you gave to J. W. W. data for rewinding a compound-wound dynamo for a higher voltage; will the machine run at the original speed after being rewound? (2) What is the formula for rewinding machines for different voltages at the same speed? (3) What is the formula for rewinding for a different voltage and different speed? J. J. H.

Practically the same speed. (2) Divide the voltage for which the machine was built by the voltage to which it is to be changed; multiply the result by the cross-sectional area of the wire now on the machine, and the final result will be the cross-sectional area of the wire to be used in rewinding. This applies to both the armature and field windings of the machine. The shunt field winding should occupy the same cubic space as before. To ascertain the number of turns for the new series field winding, or the new total number of turns on the armature divide the original voltage by the original number of turns and multiply the result by the proposed voltage. The proper division of the total armature turns into individual coils is a matter of dynamo design and cannot be covered by a mere formula. (3) There is none; no such radical changes can be made successfully without knowledge of dynamo design.

Can a dead short-circuit across two commutator bars of a dynamo or motor be located without removing any of the armature leads from the commutator lugs? (2) What is meant by the rating of an induction regulator at so many kilowatts? (3) What is the difference between a current transformer and a potential transformer? E. M.

Yes; secure the armature so it cannot turn, pass full-load current through it by means of connections from the brushes to a supply source in series with a regulating resistance, such as a water rheostat, and test the difference of potential between each pair of adjacent commutator bars all the way around. If at any pair of bars there is no deflection whatever of the voltmeter needle, those two bars are short-circuited together, either in the commutator itself or in the armature coil connected to them. The voltmeter must be very low-reading, the full scale being not more than 10 volts. (2) That the maximum counter e.m.f. of the regulator, multiplied by its maximum current capacity equals its rating in *watts*. (3) It is purely structural; the current transformer has a very low-resistance primary winding—frequently a single turn of conductor—and the potential transformer has a high-resistance winding. The former is connected in series with the work circuit while the latter is connected in parallel with the circuit.

A MODERN HOT AIR ENGINE.

BY G. EMIL HESSE.

In these days of industrial activity it is only natural that the external combustion engine, as represented by the Ericsson type, should receive the attention which the hot air engine deserves, especially as the internal combustion engine, which belongs to the same class, has met with such pronounced success both from a technical and a commercial standpoint.

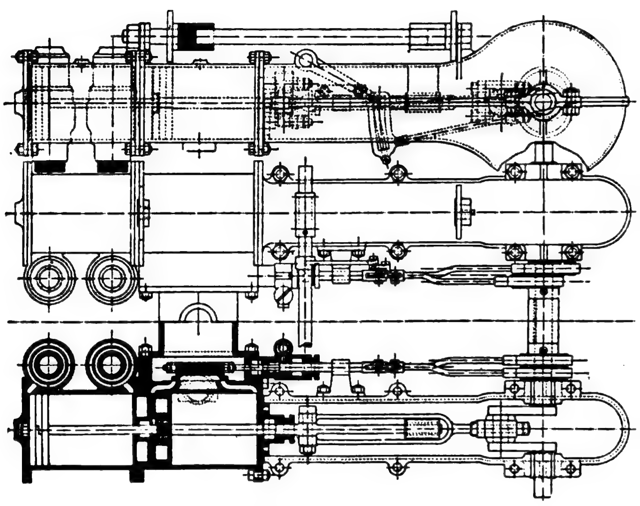


FIG. 1.—6-H.P. SVEA CALORIC ENGINE.

So many inherent, natural difficulties had to be overcome when the gas engine was first taken hold of, and so many still remain, in spite of the time and skill bestowed upon it, that it is a pleasure to record the perseverance of the pioneers in this industry. A rapid way of heating the air had been discovered, however, and the builders knew that they were building on the right foundation.

It was for this reason that the external combustion engine was neglected.. The means employed by Ericsson to heat the air by simply allowing the warmer air, nearest to the heated plates, to rise into the cooler layers above, is too slow to allow its adoption for even a few horse-power.

This was thoroughly demonstrated by Ericsson himself, who built several large hot air engines and the impracticability of heating large volumes of air in the manner employed was well recognized by the creative element in the engineering profession, who severely left it alone for the better method, offered by the internal combustion engine.

If boiling oil is poured on top of cool water it will be found that the heat is only slowly communicated to the layers below, but heat the water from below and it is done rapidly.

Air heated by the ascent of the warm layers into the stationary above is slow, but allow a cool and well divided up body of air to pass over the heated plates at a velocity, which is under absolute control, and the result will be satisfactory. It is well known that the hot gases generated in the furnace on their way through the tubes of a boiler give off the heat to the water. It is this system reversed which is employed in the Svea caloric engine.

The cool air sweeps over the heated plates in a finely divided state at a certain velocity the whole body of air moving and none stationary as in the Ericsson engine, absorbing on its way the heat emitted from the plates. In the large stationary or marine type the air is used under pressure, as in the Rider and Lehmann type, and is used over and over again, but the system of heating it is the same. This, it is claimed, will make the Svea type practical for the largest power without prohibitive size or weight.

The Svea Caloric Engine Co. is now building a six-horse-power engine, applicable for launches, automobiles, etc., and has under way a 100-h.p. stationary engine. The cylinder of the 6-h.p. engine is 4¼ inches in diameter, with a stroke of 4⅞ inches making 450 revolutions per minute. It is self-starting, double-acting, reversible, and, it is claimed, easily controlled, which makes it suitable for all classes of work. The heater is 20 inches in diameter, 16 inches long, and has a heating surface of 60 sq. ft. The total weight of engine and heater complete is 450 pounds, as compared to 1700 pounds for a ½-h.p. Ericsson engine.

The saving of coal accomplished by the hot air engine lies in the fact that it utilizes a medium, which is already in a vapor and consequently does not require the large amount of heat, which water does, before it is vaporized. This is considerable, and is an absolute loss no matter whether it goes into the atmosphere or the condenser.

One kilogram of water at 100 degs. C. requires an expenditure of 537 thermal units, before it is converted into saturated steam of the same temperature. The saving accomplished by the condensation is:

$$\frac{10{,}334 \times 1{,}649}{424\left(\frac{10}{9}-1\right)}\left[1-\left(\frac{1649}{14.55}\right)\right]^{\frac{1}{9}} = 76 \text{ units},$$

making a total net loss of $537 - 76 = 461$ units.

This explains why there should be a great future for the hot air engine. No economy is claimed for the Ericsson engine, which in fact is a fuel eater. The reason for this is that most of the heat goes through the chimney and also on account of the large heat-radiating surface per horse-power exposed to the air. The exposed surfaces of both heater and cylinders of the Svea engine are not larger than those of the steam engine plant. It is besides possible to utilize the heat generated in the furnace in the same economical manner as in a boiler, thereby putting it on an equal footing with the steam engine. No cooling water is needed for the cylinder, which is a great saving, a fact well known to the gas engine designer.

WESTINGHOUSE SINGLE-PHASE RAILWAY SYSTEM.

The successful introduction of an alternating-current railway system removes many of the limitations which have been felt under former conditions, and opens the way for an immense development of electric traction. The new system retains

FIG. 1.—CENTENARY LINE CONSTRUCTION.

some of the best characteristics of the direct-current system; namely, a single working conductor, and the speed-torque characteristics of the series motor, while eliminating many of the weak points inherent in that system.

FIG. 2.—BOW TROLLEY.

The great superiority of the alternating current for the generation and transmission of power has long been recognized, and means have been found, through the rotary converter, to partially utilize alternat-

ing current for railway operation. This is accomplished at the expense of increased complication, and the comparatively low trolley voltage and rheostatic losses still remain.

The Westinghouse single-phase railway system, it is claimed, possesses the successful features of the direct-current system, with efficiency and elasticity of service greatly increased. Expensive rotary converter sub-stations are replaced by small transformer houses containing apparatus, which requires only occasional attention.

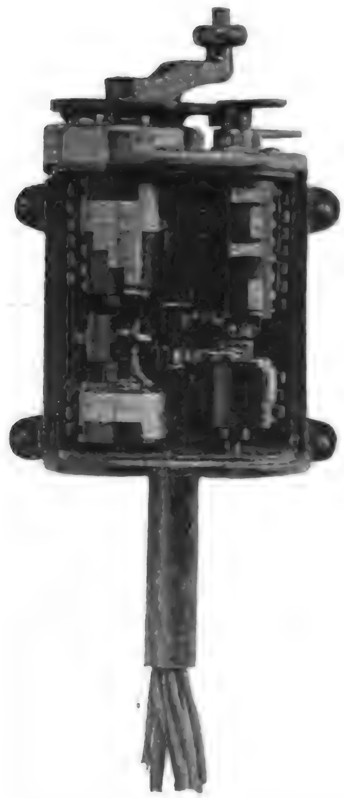

FIG. 3.—MASTER CONTROLLER FOR MULTIPLE CONTROL.

Line losses are decreased, and rheostatic losses practically abolished. The power is supplied to the car at a high voltage, so that the difficulties of collecting heavy currents are eliminated. The method of voltage control enables emergency conditions to be economically met. As transformers are interposed between all apparatus and the line, the problem of protecting single-phase motors from lightning becomes very simple.

A frequency of 25 cycles is standard for the Westinghouse single-phase system. This frequency is now used in most existing railway and power installations, so that the new system is perfectly adapted to present systems of generation and transmission.

The single-phase system involves no complications in the generating stations or transmission line. Standard polyphase generators with a frequency of 25 cycles are used. The generation and high tension transmission may be single-phase, two-phase or three-phase, according to local conditions but the ease of changing from two to three-phase, or *vice versa*, by transformer connections makes it possible to adapt the whole or a part of any existing system to single-phase railway work.

The high voltage of the transmission is stepped down through transformers to the voltage used on the trolley. The transformers used for this purpose are placed at the proper points along the line, usually in small transformer houses. In these houses is also placed the proper overload and lightning protection; there is no moving machinery, and only occasional inspection is required. The contrast between such a station and the rotary sub-station is very marked, and the absence of attendants is an item of no small importance, while the decreased complication is certain to result in improved continuity of service. In some cases the transformers are mounted on trucks and the spare transformers kept at central points along the line, so that when it is necessary to repair a transformer at any station it may be replaced by another taken from one of the central points. This practice reduces the number of space transformers required, as well as the number of repair men. In other cases, where the traffic is temporarily increased on some section of the line, as by some great gathering of people on certain days or certain seasons of the year, spare transformers may be placed on a car, and a temporary transformer station readily installed, to reduce the loss in the trolley. Such an arrangement materially cuts down the cost of transformer equipment. The distance between transformer stations depends on the trolley voltage used, the density of the traffic, etc.

The standard trolley voltages are 2200 and 3300 volts, though in cases where it is required, a lower voltage may be used within city limits. For changing the connections on the car in passing from one voltage to another, a simple change-over switch is all that is necessary. In many cases of suburban and interurban service all trolley feeders may be dispensed with, the trolley itself being sufficient to carry the necessary current. Union standard or bow trolleys are used according to trolley voltage and speed of cars.

An auto-transformer installed on each car supplies the motors, reducing the voltage of the trolley to 250 volts, which is

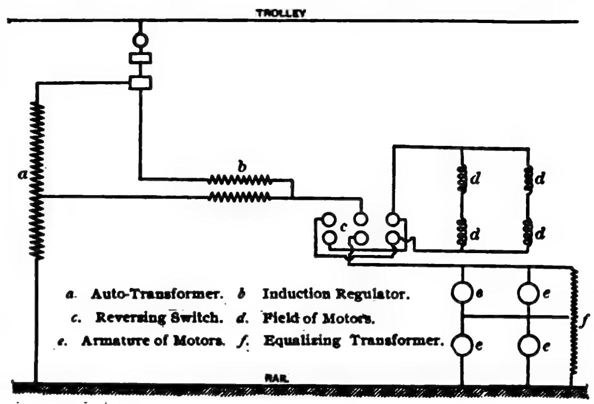

FIG. 5.—DIAGRAM OF CONNECTIONS

standard for the motors. The lamps, heating apparatus, and the small motor which drives the air-pump for braking, etc., are also supplied from an auto-transformer.

The induction regulator is virtually an auto-transformer with movable secondary, which is used to vary the voltage at the motor terminals. The variation is produced entirely by induction, without breaking any circuit in passing from one voltage to another. The regulator is connected in series with the circuit, and its variable voltage is added to or subtracted from that of the main transformer.

The regulator, as well as the reverse switch and circuit-breaker is operated by compressed air from the motor-driven system. The control is through a small controller, which operates electromagnetic valves by means of current from a storage battery. This system of control is said to be admirably adapted to multiple unit operation, and an equipment may be operated continuously, it is said, on the lowest speeds, maintaining good efficiency and a smooth motion. This feature is important in city work when, to obtain the low

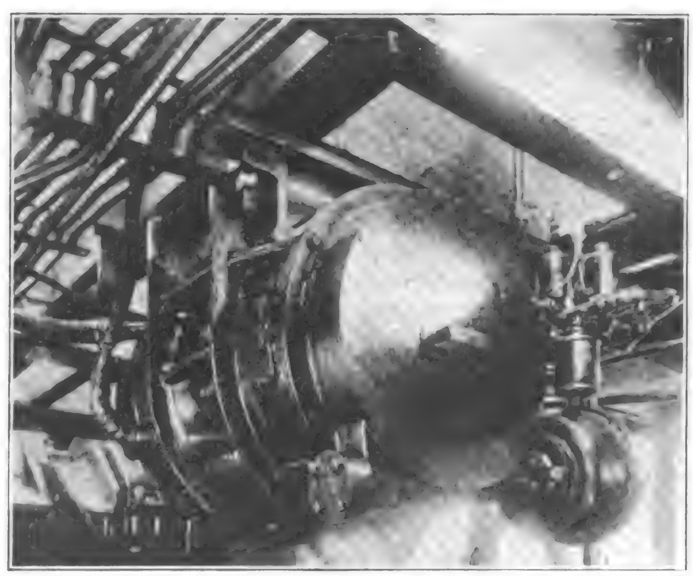

FIG. 4.—MASTER CONTROLLER UNDER CAR.

speeds required, a direct-current equipment must be moved by a series of jerks, since the resistance is not designed for continuous operation at low speeds.

With the alternating-current system of voltage control every point is a running point. The two coils of the regulator are shown diagrammatically in Fig. 5. They are wound on separate cores, and so mounted that their relative angular position may be varied at will. The primary coil, *b*, is connected between the trolley and the motors. One end of the secondary coil is connected to the auto-transformer, *a;* the other joins the primary at the motors. This arrangement provides a voltage range double that of the regulator, and consequently permits the use of a smaller size than would otherwise be possible.

The air for operating brakes and other apparatus is held in reservoirs in which the pressure is maintained constant by a small single-phase motor in a manner similar to that used in large direct-current equipments.

The Westinghouse single-phase railway motor is made in standard sizes of 50, 75, 100 and 150 horse-power, nominal rating, and the line includes motors suitable for practically every class of service. The normal rated voltage of these motors is 250 volts. This low motor voltage, combined with a high trolley voltage, the manufacturer claims, is the ideal condition, and is made possible by the use of transformers, as previously explained.

In general appearance the single-phase railway motor differs little from the standard direct-current forms. It is of the box type, the outer frame being of cast steel, and supporting the annular laminations of the field. The end brackets are accurately fitted on machined seats and carry the armature bearings, which are of the most modern type. The brush-holders are also bolted to the end brackets. The armature closely resembles that of standard direct-current motors in general appearance. It is of the drum type, and is provided with generous ventilating spaces between the laminations. The bearings and shaft are of ample dimensions, and the entire mechanical design embodies the results of a wide experience in the manufacture of railway motors.

FIG. 6.—100-H.P. SINGLE-PHASE RAILWAY MOTOR.

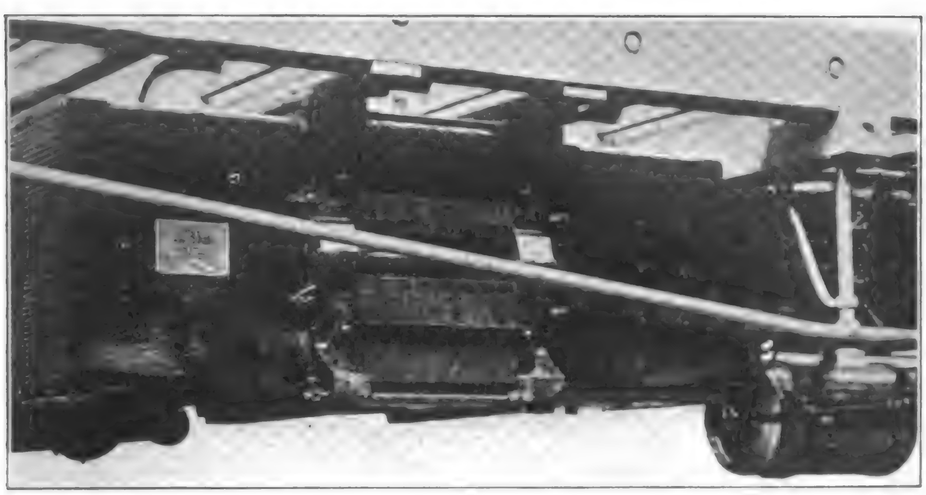

FIG. 7.—AUTO-TRANSFORMER UNDER CAR.

Every motor is subjected to a rigid test and careful inspection of every part while in process of construction. This is supplemented by a final run under load, after which the insulation is given a high-potential break-down test.

Although the system just described is in its primary form a straight alternating-current system, when provided with the proper controlling devices, the motors may be used on direct-current circuits, so that suburban roads may, when it is necessary, run cars into or through towns or cities, using the direct-current trolleys already installed. Where such an arrangement is used, the motors are generally connected in series, and their speed controlled by the ordinary rheostatic system. The adaptation of single-phase motors to direct-current circuits enables the change from a direct to an alternating-current system to be made gradually—operating extensions to the system by alternating current, replacing old direct-current motors as fast as necessary by single-phase motors, and finally changing the whole system, removing all rotary converters, trolley feeders, etc. The accompanying engravings are of a road now in operation.

"TYPE N" LOMBARD GOVERNOR.

The Lombard Governor Company, Boston, Mass., has placed on the market an entirely new type of hydraulic governor which is especially adapted for the requirements of large stations. This new governor is made in two styles, both of which are vertical; Fig. 1 illustrates the vertical type. One large casting forms both the main cylinder and the bearings for the terminal shaft. The base forms the lower cylinder head, and the upper cylinder head is integral with the cylinder; this form of construction being used to obtain maximum strength with the least weight of metal, and to obviate the possibility of joints loosening under the great stresses involved. The straight cylinder construction with piston motion along the axis is retained for the economy of metal and symmetrical distribution of stresses which have been found by experience to be thereby obtainable. The linear motion of the piston is transformed by racks and pinions to rotary motion at the terminal shaft. In order to reduce the vertical height of the governor and also to transmit the force at the piston to the rotating shaft efficiently, double racks and pinions are used, the racks being connected to an equalizing yoke, and the racks are located alongside the cylinder instead of beyond it as has been the custom heretofore.

The steel terminal shaft is 2 15-16 in. in diameter, and it is supported by bearings both sides of the pinions; the total length of bearing of this shaft is 26 inches. The releasing clutch mechanism is of the well-known Lombard design, properly proportioned for the power of the machine. All keyways are extra wide, and the terminal shaft pinions are not only keyed, but also shrunk on at a high temperature. The main piston-rod gland cap is cup-shaped so as to prevent leakage over the machine. The usual form of hand-wheel is employed; this is out of gear when the governor is in regular operation. The working fluid for this governor is a special oil kept under pressure in a vertical draw steel tank. Oil is forced into this tank by a powerful pump which is part of the equipment of the governor.

The special novel feature of the "Type N" governor is the relaying valve mechanism. In the earlier types of Lombard governors, an ingenious mechanical relaying device was used to multiply the comparatively small force and movement of the centrifugal balls sufficiently to control accurately the main valve of the hydraulic cylinder. This mechanism consisted of a combination of an auxiliary valve a small hydraulic cylinder with two outside racks, and a floating gear. As the size of governors increased, this style relaying mechanism proved rather cumbersome, occupying too much valuable space and complicating the remainder of the machine to an undesirable extent. Therefore, there was invented a hydraulic equivalent for all this outside mechanism which has made it possible to build governors of any size and proportion without conforming the design to the relaying device as was formerly the case. This new relaying device is said to have given in service considerably better results than have ever been obtained before by any other mechanism.

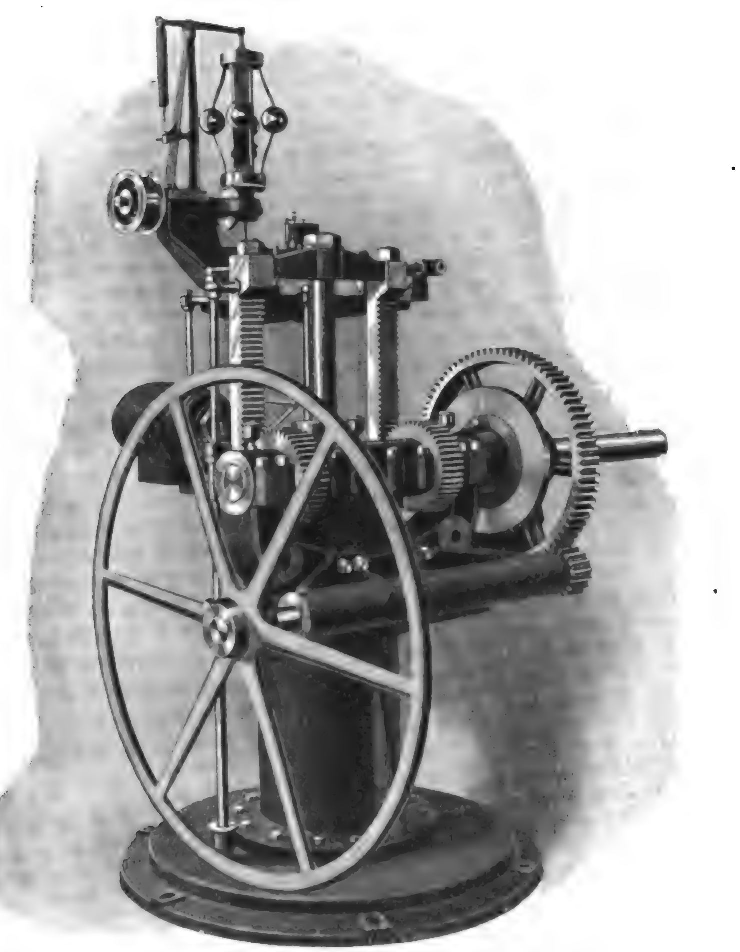

FIG. 1.—TYPE "N," LOMBARD WATER-WHEEL GOVERNOR.

The main valve of the governor consists of a large double hollow piston contained in the horizontal cylindrical case back of the hand wheel rim at the left of the engraving. The wearing surfaces of this valve are made of hardened steel and the cylinder in which it travels has a hardened steel sleeve or bushing through which the ports are cut. The valve itself is perfectly balanced, so as to require comparatively slight force to move it. Reliance is not placed, however, on this fact, but powerful hydraulic plungers, supplied from the pressure system of the governor, are provided to insure its movement. These plungers are under the simultaneous control of a very small primary valve attached to the stem of the centrifugal balls and of a small valveless displacement pump in the slender vertical cylinder at the left of the engraving. The piston of this pump is attached to and moves with the main piston of the governor. The relation of these parts is such that the least displacement of the primary valve by the centrifugal balls causes an instantaneous and positive movement of the large main valve. The main valve is immediately restored to its closed position by the action of the displacement pump as soon as the primary valve is again closed. There thus results an exact immediate magnification by the main valve of the movement of the primary valve, and this magnification is the principal reason for the accurate speed regulation given by this governor. In an ordinary hydraulic governor the least speed variation which will produce motion of the governor depends upon the lap of the valve controlled by the centrifugal weights; the smaller the lap the greater the sensitiveness. On the other hand, small lap of the valve is conducive to large leakage and short life. With the relay valve form of construction used in the Type N governor, the lap of the main valve influences in no way the sensitiveness of the machine and still insures freedom from leakage. In order to take the utmost advantage of this feature of its construction the Type N governor is provided with a primary valve having an outside micrometer adjustment for varying the amount of lap. By this means it is easy to alter the sensitiveness of the governor while it is running so that it will respond to speed changes of greater or smaller magnitude down to the limit where the governor is kept in motion by speed changes too small to detect. This micrometer adjustment also serves to take up the loss of lap of the primary valve due to wear.

The anti-racing mechanism of the Type N governor is of the well-known type used in Lombard governors for many years. Certain improvements have been made in the nature of adjustment and in design, however, so that the effect in making the governor dead beat is much more marked at the beginning of the stroke, when the water-wheel gates are just opening.

The capacity of the Type N governors is said to be much greater than that of any standard governor manufactured hitherto. The piston is 10 inches in diameter with a 24-inch stroke, and 200 lbs. per square inch is the normal pressure, so that the governor exerts 31,000 foot-pounds of energy per stroke. The factor of safety under this pressure is ample. Under emergencies the pressure has been increasd over 50 per cent without harm to the governor.

Persons actually interested in the object may be even more interested in seeing results obtained by the use of this governor than by a mere description of the machine itself. Any one feeling thus is cordially invited to visit the new Lombard factory at Ashland, Mass., where these governors may be seen under service conditions, regulating full-sized turbines. Fig. 2 is a *fac simile* of a speed recorder strip obtained in service with a Type N generator.

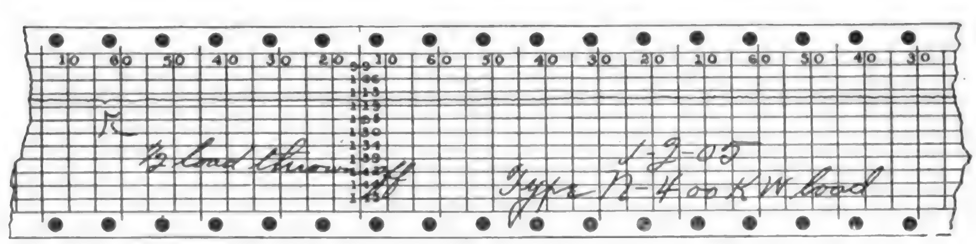

FIG. 2.—SPEED RECORDER STRIP.

New Apparatus and Appliances

MURRAY FEED-WATER HEATER AND PURIFIER.

The open feed-water heater and purifier, shown by Fig. 1 herewith, is made by the Murray Iron Works, of Burlington, Iowa. The supply is regulated by an automatic float valve which admits only as much water to the heater as the boiler requires. The water first passes over a series of removable pans which catch such impurities as precipitate at a temperature of nearly 212 degrees. From here the water passes to the settling chamber where oil and such other impurities as come to the surface of boiling water are skimmed off, the water being in contact with the exhaust steam from the engine all the time. The water thus purified passes to the pump suction chamber through a series of syphon goose-necks, which take the purified water from beneath the surface in the settling chamber only. Three-sixteenth-inch holes are provided in the goose-necks one-half inch above the main openings, so that the syphoning is stopped by the admission of air into the goose-necks when the surface of the feed-water falls below these holes in the goose-necks. The water in this chamber is kept hot by the exhaust steam pipe that passes through it. The heater, it is claimed, creates no back pressure, condenses part of the exhaust steam, purifies the feed-water as well as heating it to the maximum temperature attainable by this method.

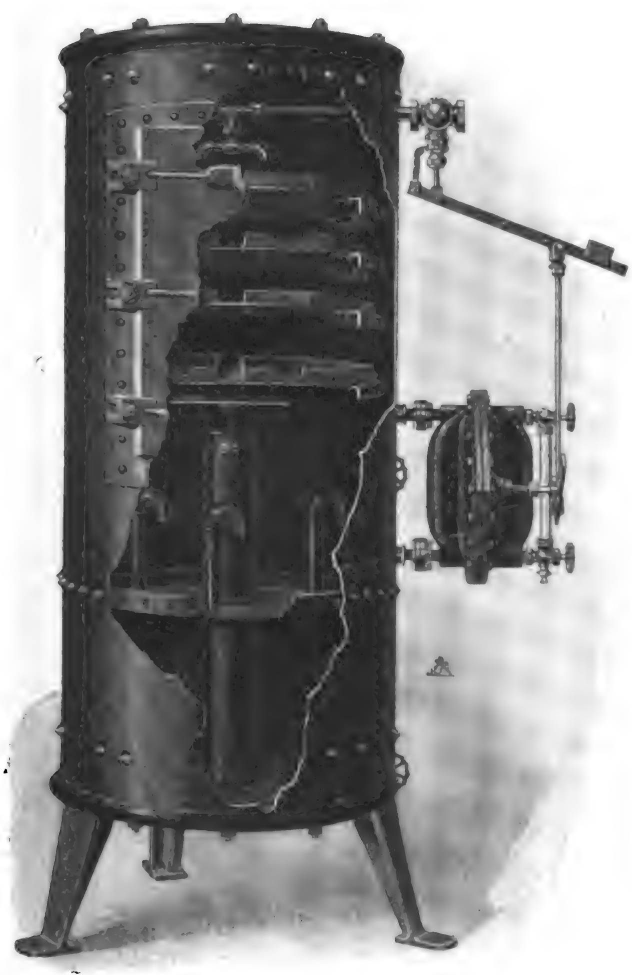

FIG. 1.—MURRAY OPEN FEED-WATER HEATER AND PURIFIER.

CONTROLLER FOR BOILER FEED PUMPS.

The controller for boiler feed pumps illustrated herewith is essentially a governor for the pump which is controlled by the relative pressure of the steam and water. This is made clear by reference to the illustration, from which it is seen that the working parts are a balanced valve and a differential piston. The initial steam pressure being on the ends of the valve, has access, through the neck, to the full area of the piston and will force it into a position giving a full valve opening, where it will remain until overcome by the water pressure from the pump acting against the opposite side, which is of reduced area. The excess pressure required to overpower the initial steam pressure is equal to the reduction of area on the water side of the piston; so that were the reduction 10 per cent., the water pressure must be 10 per cent. greater than the steam pressure to give the same thrust on the piston. When this pressure is reached the valve is held only wide enough open to admit steam to the pump to keep up this excess pressure. If this excess pressure should become greater, the steam valve is forced nearly closed, thus nipping the cause of the rise namely, too great a piston speed. The water-pressure varies only as the steam pressure varies, always keeping the same per cent. of excess. The controller is made by the Federal Valve Company, of Seattle, Wash.

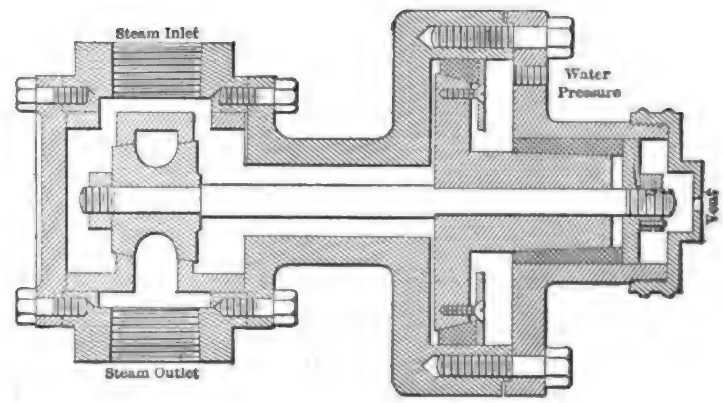

FIG. 2.—AUTOMATIC CONTROLLER FOR BOILER FEED PUMPS.

CHOKE COILS FOR PIPE THAWING OUTFITS.

Quite a number of thawing transformer outfits are now on the market, embodying more or less complicated regulating devices but it has seemed to some that it is needless to tie up a transformer to such intermittent service. Realizing that nearly all central stations carry a few reserve transformers for emergency requirements, the Peerless Electric Company, of Warren, Ohio, has brought out the regulating or choking coil shown by Fig. 3 herewith. The coil can be utilized with any make of standard transformer having sufficient size. This affords a most successful thawing outfit at moderate cost, and leaves the transformer available for ordinary use. The apparatus consists of two coils of heavy copper bar, having large carrying capacity, in connection with which are two plunger cores of laminated steel, to be raised from or lowered into these coils for the purpose of either increasing or decreasing the amount of current as desired for various

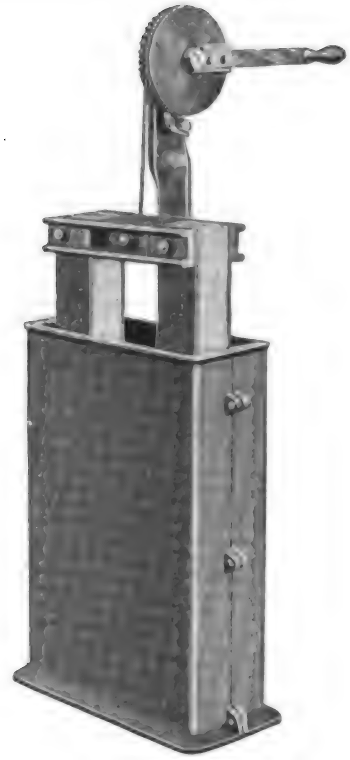

FIG. 3.—PEERLESS CHOKE COIL.

sizes and lengths of pipe. The current traversing the pipe is heavy enough to readily heat it to a degree of temperature for thawing purposes, but not to cause injury, even though this be very small iron or lead service pipe. The regulating coil is well made and exceedingly simple in its working parts. The windings are given an insulating treatment that renders them water-proof, and are enclosed in a strong iron case. The core is raised or lowered by a simple device, operated by a hand wheel with cable and ratchet attachment, which is strong and positive in its action. The apparatus is designed to be used with any standard 110-volt transformer, either 60 or 133 cycles, of capacity from 10 to 30 kilowatts. Properly installed in connection therewith, injury to the transformer from short circuit is impossible, as the choking effect of the coil is such that only normal current will flow in secondaries of transformer even though the leads be short-circuited when the plunger is inserted its full length in the regulator. The coils are equipped with heavy terminals for connecting up cable leads. Results vary so greatly, according to conditions, that a definite schedule covering exact working voltage, length and diameter of pipe and time necessary to thaw the same cannot be given; but the maker claims that with the choke coil herein described, the temperature of 100 feet of ½-inch iron pipe frozen solid can be raised 20 degrees in five minutes. There is no danger of ever melting the pipe, as the ice or water contained therein is an ample safeguard. As soon as the water begins to flow freely, the work is done. With each apparatus is furnished a blue-print plainly showing the connections to the choke coil and the transformer, and also containing full directions.

THE ZEEK BORING TOOL.

Fig. 4 herewith shows the Zeek boring machine manufactured by James McCrea & Co., Chicago, Ill. The device is intended

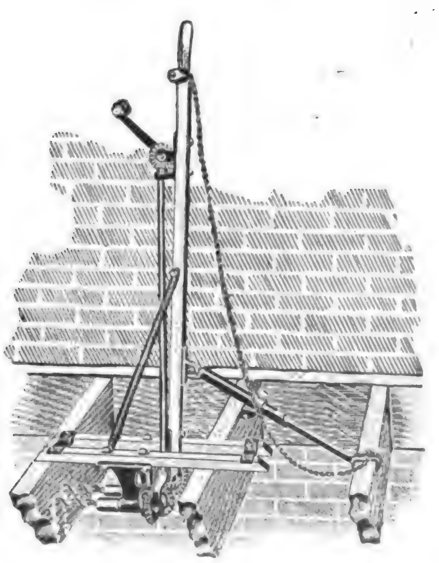

FIG. 4.—ZEEK BORING TOOL.

for boring holes below while standing on the joist. It bores two holes at once, 3¾ inches from center to center and 3½ inches from the top of the joist, which is a sufficient distance to void nails. The operation is said to be both easy and rapid, since the operator stands upright to his work. All holes are on a line, insuring a straight run of wire as well as all the other advantages of straight work. The method of operating the machine is clearly shown in the engraving.

NEW PROTECTED SWITCH.

William T. Pringle, of Philadelphia, Pa., has brought out the "Underwriters" switch shown by Fig. 5 herewith. The contacts are all protected with a porcelain cover, which does not have to be removed to op-

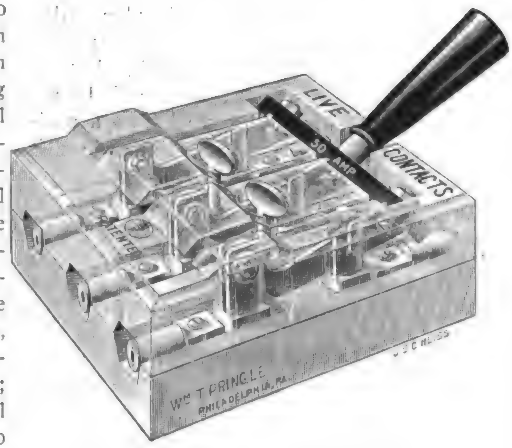

FIG. 5.—PRINGLE "UNDERWRITERS" SWITCH.

erate the switch, so that all liability of accidental contact is avoided. The metal parts are said to be strong and substantial and the contacts are set in grooves to insure perfect alignment. The contacts are made of rolled copper designed with ample margin of safety both for current and voltage. The switch is made for 25 and 50 amperes, both double and triple-pole.

EXPERIMENTAL DYNAMOS AND MOTORS.

The R. M. Cornwell Co., of Syracuse, N. Y., is putting on the market a complete line of experimental dynamos and motors from the smallest made up to a 1-kw. machine for commercial purposes. The accompanying illustration shows the "Wonder" dynamo, which is claimed to be the smallest generator of its kind on the market. It has an output of about 12 watts, and is wound for a number of different voltages

FIG. 6.—EXPERIMENTAL DYNAMO.

In bringing out this machine it was the aim of the company to put on the market a small generator following in every detail the construction of large commercial machines. Among its special features are its laminated armature, adjustable brushes, large and strong commutator, heavy interchangeable bearings. The machine is for use where a small amount of current or power is required, especially in connection with experimental work. As a motor the machine is said to operate running light on about 2 watts, and with sufficient battery will do a considerable amount of work for its size. The machine is also wound to run in series on 110-volt lighting circuit. All parts are interchangeable.

HORNBERGER-IRWIN TRANSFORMER.

The accompanying illustration shows the multi-coil core type of Hornberger-Irwin transformer made by the Crawfordsville Electric Company, of Crawfordsville, Ind. This is the style of construction used in all but the smaller sizes of transformers made by the company. By reason of this practice the difference of potential between layers at the end of the coils is reduced to a minimum, it is claimed, and the low temperature of the core maintained since it is directly exposed to the radiating medium at intervals through its entire length. A sheet steel case is used on transformers from 20 kilowatts to 100 kilowatts. This is not only less weighty than a cast iron case, but also dissipates the heat more rapidly. For sizes larger than 100 kilowatts, the case is corrugated. The complete transformer being made up of many coils, each having the required number of ratio turns within itself, all coils being then connected in multiple to the terminals, a possible disablement of one coil does not mean that the transformer must be entirely replaced; but only that coil

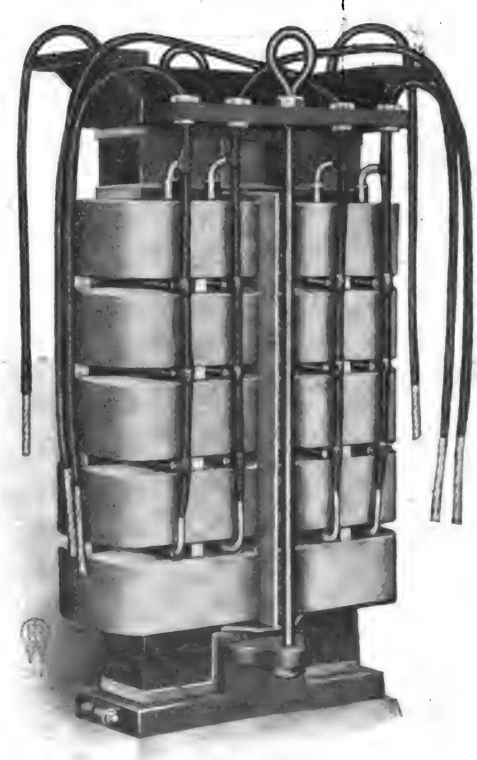

FIG. 7.—HORNBERGER-IRWIN TRANSFORMER.

which might be injured. As the correct terminal voltage is obtained, even were a number of coils removed from the transformer, its operation is affected only to the extent that its capacity would be reduced

by the number of coils not in operation. The company claims to have overcome the objections usually made against the core type of transformer, *i.e.*, the excessive voltage between layers at the end of the coils, and the internal temperature. All transformers are carefully tested before shipment. A break-down test of 10,000 volts is applied between the primary and secondary windings, as well as between the windings and the core. Electrolytic copper and mica are used for conductors and insulation throughout.

BALL BEARINGS FOR ELECTRIC MACHINES.

The Hess-Bright Manufacturing Company, Philadelphia, Pa., are introducing the ball bearing shown by Fig. 8 herewith. In this type of bearing the racers are without joint or opening of any kind, so that the bearing can be used without reference to the direction of the load, or whether it is the shaft or the hub that revolves. The balls are separated by interposed springs. When these are compressed the inner race can be pushed over eccentrically so as to permit the balls to be inserted or removed. The number of balls is, therefore, less than with the "full type" bearings, the decrease in carrying capacity being compensated for by increased ball diameter. At high speeds this type of bearing is claimed to be absolutely silent. A wool pad in the spring between the balls soaks up oil, and will keep the ball sufficiently lubricated in case of neglect. The bearing takes up only a small space endwise; including the oil-retaining and dust-excluding arrangements, this is said to be less than the width of framing necessary to sustain the hub receiving the bearing. The races are made from high-grade steel; likewise the balls. The races are ground close to size as concerns their seat on the shaft and in the box, so that interchangeability is assured. The ball tracks are accurately ground to shape and polished. The company also makes the "full type" of roller bearing. In this type the balls are filled in through an opening in the side of the race, which is closed by a screw or clip through which the race is ground. The advantages claimed for the "Universal" type are the following: Small friction; small oil consumption; small wear; small space occupied; small attention, and convenient exchange. Fig. 9 shows the ball bearings applied to the shaft of an armature built by the Electro-Dynamic Company, of Bayonne, N. J.

FIG. 8.—"UNIVERSAL" BALL BEARING.

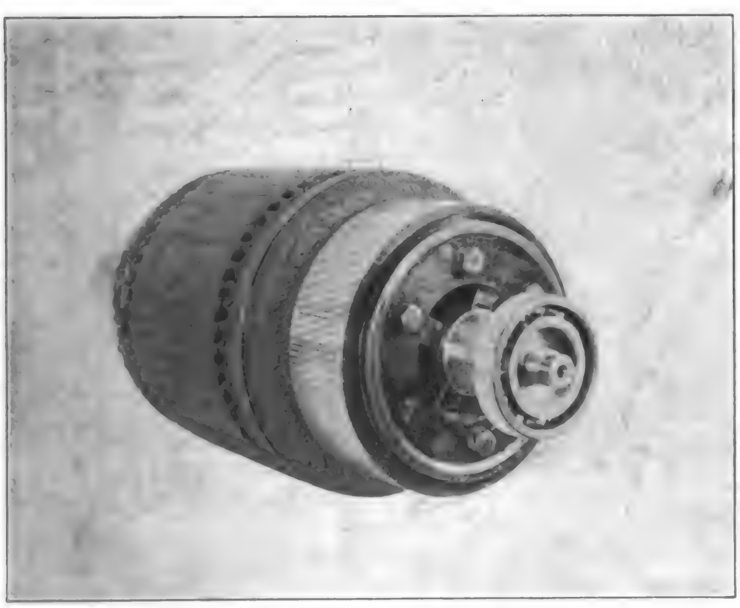

FIG. 9.—BALL BEARING APPLIED TO SHAFT OF ARMATURE.

AUTOMATIC BOILER FEED REGULATOR.

The Copes automatic boiler feed regulator consists essentially of two parts—the feed controller and the pump governor. The regulator is placed entirely outside the boiler, and consists of nothing but copper tubes, check valve, toggle, cylinder and piston. The connections are shown diagrammatically in Fig. 10. A ¾-in. copper pipe, 6 ft. long, is screwed into a special fitting at the lower left-hand corner at about a 30-deg. angle, to allow all condensation to return through the horizontal pipe to the boiler.. This constitutes the feed controller. The water column is tapped at the water level of the boiler and a ¼-in. pipe is connected as shown. Steam entering the copper pipe causes the latter to expand and open the check valve through the intervention of the lever to which it is attached. When this check is released, the pressure in the feed line is less than the steam pressure, thereby causing the piston of the pump governor to rise and admit steam to the pump. As soon as the water in the boiler covers the opening tapped in the water column, the expansion tube contracts and the check valve is closed. This causes the piston of the pump governor to shut steam off the pump. The agents for the regulator are Thorpe, Platt & Co., New York City.

ELECTRIC BLUE-PRINTING MACHINES.

Fig. 11 herewith shows an electric blue-printing machine made by the Buckeye Engine Company, Salem, Ohio. Each machine is equipped with two rollers, one on each side, which carry the contact curtain and are operated independently, so that just one side may be used and one side may be unloaded and reloaded while the other is printing. The contact curtain is held firmly to the surface of the glass by means of weights attached to small wire cables engaging both ends of the rollers which carry the curtain. By this arrangement perfect and even contact over the entire surface of the glass is said to be secured. No buttons or clamps or any mechanism whatever is required for fastening the curtain to the frame, and holding it in place after it has been unrolled. The rollers, it is claimed, remain stationary at any point on the circle and the curtain back of the roller is in perfect contact with the glass regardless of how far it has been unrolled. The lamp furnished with the machine is especially constructed for photo-engraving and blue-printing work. It is of the long-arc construction transmitting a light rich in actinic or violet rays. A lamp is furnished to operate on either direct or alternating current, and at any voltage. A rheostat is furnished with each lamp to adapt it to the current desired. The pendulum governing the drop of the lamp is adjustable as to speed, thus removing the necessity of making more than one drop of the lamp at a printing, regardless of the condition of the tracing. The roller device is so constructed that the machine may be readily loaded and unloaded while the glass cylinder is in the vertical position. All arrangements for tilting the frame to a horizontal position

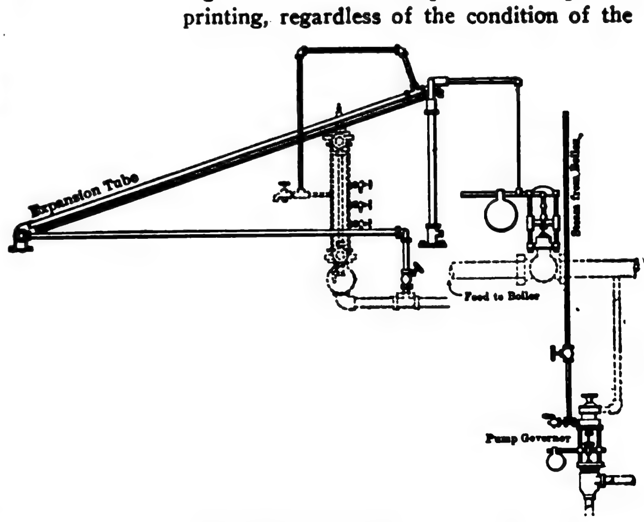

FIG. 10.—AUTOMATIC BOILER-FEED REGULATOR.

are dispensed with. The operation of the apparatus calls for no particular skill and

FIG. 11.—BUCKEYE BLUE PRINTING MACHINE.

requires the attention of but one person in connection with his other work, or it can be manipulated by a boy as satisfactorily as by a skilled workman. The machine is made in two styles, designated A and B; the first making prints 42 ins. by 44 ins., and the second making prints 42 ins. by 60 ins. The machine requires a floor space of 3½ by 3½ feet, and the height over all is 9 feet.

PORTABLE ELECTRIC GENERATING SET.

The accompanying engraving shows a portable electric generating outfit consisting of a 4-h.p. Mietz & Weiss oil engine, belt-connected to a 2¼-kw. General Electric generator. The engine uses ordinary kerosene oil and has a fly-wheel governor instead of the hit-and-miss type of governor generally used, so that the regulation is said to be quite close, and, of course, suitable for electric generating purposes. The operation of the Mietz & Weiss oil engine is so well known that its repetition would be superfluous. Tests made on the engines driving dynamos have been repeatedly made and show that the speed variation between no load and full load is very slight. The builder of the engine, A. Mietz, of New York City, informs us that the Japanese government is using sixteen 4-h.p. stationary Metz & Weiss oil engines.

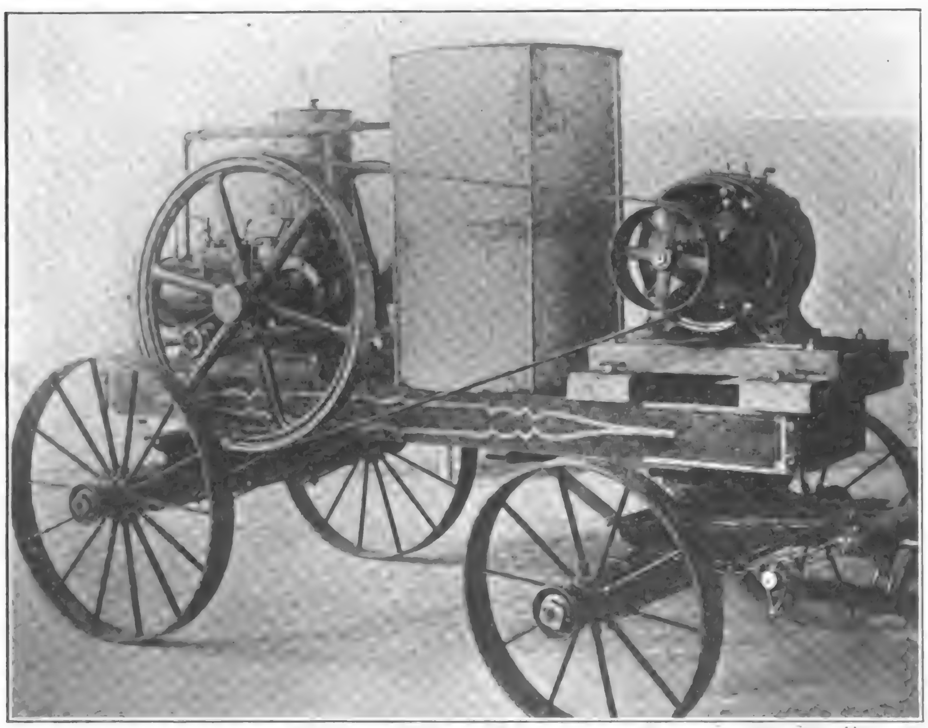

FIG. 12.—PORTABLE ELECTRIC GENERATING SET.

LOS ANGELES-PACIFIC RAILROAD.

Owing to the greatly increased traffic on the interurban railway system of the Los Angeles-Pacific Railroad Company, the officers of that company have decided to increase the capacity of the central power house at Vineyard, and to install an additional sub-station in Los Angeles. The new electrical equipment has been contracted for with the Crocker-Wheeler Company through its Pacific Coast managers, the Abner Doble Company, of San Francisco. The contract comprises one 1200-kw., three-phase, 50-cycle, engine-type generator to give 2300 volts at a speed of 125 r.p.m.; one 300-kw. motor-generator set; one 400-kw. motor-generator set; three 400-kw. transformers; three 160-kw. transformers; three 120-kw. transformers, and a 60-kw. engine-type exciter. The 1200-kw. alternator will be of the Crocker-Wheeler new revolving-field type, similar in construction to the three 4000-kw. alternators recently ordered by the California Gas & Electric Corporation. The Los Angeles generator will be driven by a 2000-h.p. compound condensing McIntosh & Seymour engine. The motor-generator sets will consist of 2300-volt synchronous motors driving 600-volt direct-current railway generators. The transformers will be built for 15,000 volts at the primary and 2300 volts at the secondary terminals, and will be of the new water-cooled and oil-insulated type recently brought out by the Crocker-Wheeler Company.

The interurban railway system of the Los Angeles-Pacific Railroad Company is one of the most extensive in the country, embracing as it does nearly 200 miles of up-to-date lines. The company owes its growth largely to the energetic and untiring work of the president and manager, Mr. E. P. Clark, who was one of the pioneer railway men of Southern California, and who has seen his system develop from a very small beginning to its present commanding position in the traction field. The system extends from Los Angeles in fan shape to Santa Monica, Ocean Park, Playa del Rey, Hermosa, Manhattan Beach, and Redondo on the ocean, and passes through the intermediate towns of Hollywood. Colegrove, Sawtelle, Sherman and Palma. In other words, the lines cover thoroughly the territory lying south of the Santa Monica Mountains, and between Los Angeles and the ocean. Most of the lines have been double-tracked, and are constructed in conformity with the best steam railroad practice. About a year ago a new central steam-driven power plant was installed at Vineyard about 5 miles west of Los Angeles, and from this station 15,000-volt transmission lines carry power to several sub-stations located at intervals over the system. It is to increase the capacity of this central power station that the additional machinery mentioned has been ordered.

ANNUAL DINNER OF THE AMERICAN TRADE PRESS ASSOCIATION.

The American Trade Press Association held on February 17th what was designated by Mr. J. H. McGraw, the president of the association, as the most successful annual meeting in the history of the organization. The meeting began with the usual banquet, at which Mr. Arthur Warren, manager of the Allis-Chalmers Company's publicity department, was the principal guest and speaker. After due attention had been given by those present to the fine collation provided by the association, Mr. Warren delivered his address, the subject of which was "A Plain Talk on Trade Journals." It was by all odds the most pithy, vigorous and non-evasive discussion of the relations between technical periodicals and their advertisers that the present writer has ever heard or read. Space limitations preclude reprinting here the complete address, but the following excerpts will illustrate the general character of it:

Industrial publicity is a new thing; it is young and still learning to walk. It sometimes seems that no one appreciates the possibilities of publicity so much as the Publicity Man himself, and its appreciation in the industrial field is a thing of yesterday morning. There is no industry, among all those represented on this occasion, that has all the publicity it needs. There is no metal-working manufactory that spends money enough on publicity. Manufacturers are accustomed to say "Publicity costs so-and-so." They are not yet accustomed to think "Publicity earns so much."

Advertising is not the mere purchase of space, but the handling of it. It costs something to handle space.

The world rains "special numbers." The special number has become as much of a burden to the flesh and spirit as the Sunday paper. It has become only another name for special pleading for extra advertising. It has been overdone.

Of the publisher who says I must advertise in his paper because I do so in his competitor's pages, and that he is "entitled" to advertising to the same extent—what shall I say? Least said, soonest mended.

Believe me when I say "Don't cut your advertising rates." Make your paper so strong in character, so attractive in contents, so necessary in information that the people it is designed for must buy every edition. Then advertisers must buy space, not because you plead with them, but because they have no alternative.

There is one nuisance that we all know about, and that is the "write-up." It is a nuisance to all concerned, and of value to none. But there is a vast difference between the "write-up," dreary, fruitless, bald and undisguised, and the timely article that has news value or interest for the commercial or industrial world. These articles are legitimate if they are well-written and informing.

There should be, and can be, closer touch between the papers and the manufacturers, and it can be obtained without the loss of independence by the press. The papers that are not independent—that are partisan and that curry favor—are the papers we don't want.

In trade and technical journalism there is one deep, elusive mystery—circulation! But the time has come when the veil must be rent. Advertisers are entitled to know the facts of circulation; they have the right to know what they are buying. You may print many copies, but how many do you sell? In other lines of business the seller has to give written guarantees. Why should publishers be exempt?

A highly interesting discussion followed the delivery of Mr. Warren's address. Two publicity managers from representative manufacturing establishments were present, and both supplemented Mr. Warren's advocacy of editorial independence by stating that the best results that their respective companies had obtained from advertising were from papers which were absolutely rigid in declining to recognize any "rights" on the part of advertisers to the use of the reading columns, and which invariably refused to publish in the reading pages any material in violation of their editorial policies.

Several well-known publishers of trade periodicals disagreed with Mr. Warren on the question of stating the paid circulation of a paper. Mr. David Williams, of the *Iron Age*, and Mr. Angus Sinclair, of *Railway and Locomotive Engineering*, said that they had never found it necessary to state circulation. Mr. Sinclair had tried it for several years and found no advantage from it, and as it entailed a good deal of extra work to get at the exact figures, he discontinued the practice. Messrs. John Hill, president of the Hill Publishing Company, and James H. McGraw, president of the McGraw Publishing Company, both favored the statement of circulation.

THE NEW FACTORY OF THE LOMBARD GOVERNOR COMPANY.

In the commercial world just as in the physical world the best measure of success is growth. By this measure the Lombard Governor Company has forcibly demonstrated the success of its products through the notable enlargement of manufacturing facilities which has been made necessary. Formerly the headquarters of this company were at 36 Whittier Street, Boston, Mass., in a good-sized but rather old-fashioned shop, where something like five floors were occupied by various departments. There was room to spare, at first, but as the demand for its products grew, it was found necessary to crowd the machinery, until finally the work could not be carried on to the best advantage. For the past two years, night work has been necessary part of the time in the whole shop, and certain machines have been running all day and all night for more than a year past. The demand for the highest grade of governors is still growing, and the company has really been forced to leave its old quarters.

The engineers of the company for a long time have desired to obtain facilities for testing its products under actual service conditions in its own shops. This has not been possible heretofore, although ingenious electric equivalents for hydraulic testing were in service. A group of fine stone buildings, situated on the Sudbury River, in the town of Ashland, Mass., was finally selected as giving all that could be desired from a manufacturing and engineering standpoint, and two months ago the Lombard Governor Company began moving into this plant. These buildings were put up at a cost of over $500,000 by the Dwight Print Works for the purpose of making print cloths. Before being entirely completed, the Sudbury River was seized by the Metropolitan Water Board to furnish drinking water for the city of Boston. This, of course, prevented the use of the mills for the original purpose, and they have lain idle in a nearly complete state for several years. The prohibition put on the pollution of the water, however, did not apply to the use of water for power purposes, and, therefore, for hydraulic testing, almost unequaled facilities are offered at this place. The volume of water flowing is sufficient for the greater part of the year to drive the entire plant, but a first-class 150-h.p. steam plant is held in reserve at all times.

The main shop, of granite, is three stories high, 210 ft. long and 60 ft. wide. The floors are without partitions, and are perfectly open except for offices and draughting room on the upper story. Slow-burning construction has been employed, which, with massive granite walls two feet thick, eliminates most of the risk from fire. The power house, also of granite, is alongside the main mill, and has a storage capacity for 1000 tons of coal—sufficient for a year's supply. In addition to these principal buildings there are a good-sized pattern and blacksmith shop where the water-wheels are located. The property includes all power privileges on the stream, a mill pond adjacent to the factory buildings, and another two miles up stream.

The main building is unusually well-lighted. The middle floor, which is about four feet above the street level, is utilized for the most important machine work. On account of the great width and length of the building, the machines, which in the old factory were located with reference to the space available, are here put in the most advantageous positions, both as regards light and the progress of the product in course of manufacture. A spur track from the New York Central Railroad delivers goods on the level of this floor at the front door of the building. Finished material and the more valuable supplies are kept in a large stockroom just at the left of the entrance. The office of the foreman and shipping clerk forms an extension of the stockroom. The tool room is located in the middle of this floor, where the average distance from the operatives will be the least. The draughting room, about 40 by 30 feet in size, is at the front end of the third floor where north light is available. The offices, adjacent to the draughting room, are very commodious.

An isolated lighting plant and connection with the Edison system of Boston have been provided. Intercommunicating telephones are used throughout the plant. Special cut-off couplings are arranged so that power may be taken either in whole or in part from the engine or water-wheels, and a load of any desired character may be thrown upon the water-wheels in order to test governors which are connected with them.

The hydraulic equipment will consist of two wheels of standard make running vertically in an open forebay with plate glass sides and end. This forebay will be well inside one of the buildings so that it will be open for inspection at all times regardless of the weather. When daylight does not furnish sufficient illumination, electric lights located under the water will make it possible to observe the action of the wheels and the gates. Means are provided for controlling either one or both wheels by

either one or two governors. It is thought that this is the first instance where full sized turbines operating under commercial conditions have been installed so that their action is made visible to the smallest detail while running. Thus the entire collection of mechanism, including the governors, may be kept under constant observation.

Excellent shipping facilities are afforded at Ashland by the main line of the Boston & Albany Railroad (controlled by the New York Central), and also by the New York, New Haven & Hartford Railroad, of which it is a terminus. Visitors may reach the factory from Boston or Worcester, via the Boston & Albany Railroad, after a forty-five minutes' ride in either case. It is also accessible by several lines of electric cars.

NEW BOOKS.

SCIENTIFIC AMERICAN REFERENCE BOOK.—Compiled by A. A. Hopkins and A. R. Bond. New York: Munn & Co.; 1905. Buckram; 516 pages, 5 ins. x 7½ ins.; illustrated. Price, $1.50.

This is a compilation of interesting information of almost every conceivable class. The scope covers the progress of discovery, shipping, navies and armies of all countries; railroads; population of the United States; libraries, publishing and printing; modes of communcation; patents, manufactures; governmental departments; mining; elementary geometry; machine elements; mechanical movements; chemistry; astronomy, and weights and measures. The technical information is given in a more or less popular style; in some cases it is very academic and in a few perfunctory—that is, merely the old hack material found in every engineers' handbook thus far published. The few pages of mathematics relating to geometrical figures are of questionable accuracy; the reviewer notes two errors in merely glancing through this section. The book contains a mass of really useful data, however, and should prove at least interesting if not always helpful.

STANDARD WIRING FOR ELECTRIC LIGHT AND POWER. (11th Edition.) By H. C. Cushing, Jr. New York, 1905: Published by the author. Flexible leather; 144 pages, 4 ins. by 6½ ins.; illustrated. Price, $1.

This edition of Mr. Cushing's well-known wiring book shows evidence of extensive revision. Several pages of connection diagrams have been added; also a chart showing the current-carrying capacity of weather-proof and rubber-covered wires according to the Underwriters' requirements, and a special section, by Mr. George T. Hanchett, on alternating-current wiring. The abstract of the Underwriters' Rules, which has always been the chief feature of the book, has been revised, of course, to accord with the changes in the Rules this year. This work had the able supervision of Mr. F. E. Cabot, chairman of the Underwriters' Electrical Committee. It is noted with some surprise that the author retains the symbol *C* in his formulas, instead of the recognized symbol *I* for current in amperes; also that the table of motor efficiencies on page 23 is rather rough-hewn, the efficiency of a 5-h.p. motor being put at 80 per cent., and that of a 10-h.p. machine (no intermediate size being given) at 90 per cent. This might easily have been made more nearly accurate without any "hair-splitting" whatever.

CYCLOPAEDIA OF APPLIED ELECTRICITY. Chicago: American School of Correspondence. Cloth; five volumes; 2154 pages, 6¼ ins. x 9½ ins.; numerous illustrations. Introductory price, $18.00.

This is a collection of writings by an imposing corps of well-known contributors to current technical literature, including, for example, Profs. F. B. Crocker, William Esty and Dugald C. Jackson; and Messrs. J. R. Cravath, Percy H. Thomas and Alfred E. Zapf. The contents in the main consists of very useful data and expository matter, and while much of the material is academic and some of it a trifle out of date, it appears to be generally accurate. The scope of the work is enormous, covering as it does, the whole domain of applied electricity. Its avowed mission seems to the reviewer to be over-ambitious in including designers and constructors of electrical machinery in its audience; it is safe to assume that the books will be absolutely useless to both classes of men, especially the designers, who have long ago tabooed the method of dynamo design adopted here. To operators of electrical machinery and apparatus, and practical workers who have not had collegiate training, the work should be of considerable value if used discriminatingly. The sections on alternating-current machinery, storage batteries and telephone engineering are especially good; most of the other sections suffer from too much catalogue rehash, and the dynamo design section is unqualifiedly worthless. The books contain, however, a great quantity of data which is of use to engineers generally, and which may make the work useful for reference to many who do not need it educationally.

ELECTRICAL ENGINEERING EXPERIMENTS. By George F. Sever. New York: D. Van Nostrand Company; 1904. Heavy paper covers; 64 pages, 5½ ins. x 8½ ins.; 22 illustrations. Price, $1.

This is avowedly a compilation of tests for direct-current machinery, the material being arranged for third-year students in Electrical Engineering at Columbia University. Inspection of the contents arouses the suspicion that the students are not expected to have progressed very far during their first two years. The tests are all useful and familiar, but most of them are of the simplest possible character and some of the instructions well suited to the intelligence of an oiler in any modern central station. The table of symbols on pp. 6 and 7, said to be in conformity with the recommendations of the American Institute Committee on Standardization, is inaccurate in some particulars; the type face used for the magnetic symbols is not that recommended by the American Institute, excepting the permeability symbol; maxwells are called webers, and several symbols which were not even suggested by the Institute Committee are included in the table. The diction is loose throughout the book; "fields" is used instead of "field winding," for example, and on page 56 we are told that when two compound-wound dynamos are connected in parallel, with the usual equalizer, if the series windings have the same resistance the total current will divide equally between them, "making the ampere-*turns* similar." Italics ours. However, the book should be useful to those having to do with direct-current machinery and not having had the advantages of a technical education, but its price is out of all proportion to its value.

OBITUARY.

EUGENE F. PHILLIPS, general manager of the American Electrical Works and president of the Washburn Wire Company, Phillipsdale, R. I., died on February 22, of combined pneumonia and heart trouble, after a very short illness. Mr. Phillips was one of the most progressive and prominent wire manufacturers in this country, and his unusual business ability and genial personal qualities had made warm friends for him throughout the electrical industry. He was 61 years old at the time of his death. He leaves a widow and two sons, who have the sincere sympathy of a large proportion of the electrical fraternity, including the writer of this paragraph.

PERSONAL.

MR. R. B. McCONNEY, an engineer well known in the Colorado mining district, has been appointed manager of the Denver office of the Allis-Chalmers Company, to succeed Mr. R. J. Cory.

MR. FRANK H. GALE, who has been a member of the General Electric Company's publicity staff for several years past, has been appointed manager of the company's New York branch of that department.

MR. H. H. PEASE, who has been connected with the Nernst Lamp Company for some time past, has been appointed district representative of the C. & C. Electric Company at Pittsburg. His offices are in the Park Building.

MR. THOS. FERRIS, formerly the Milwaukee representative of the General Electric Company, has acquired an interest in the Osage (Iowa) Electric Light, Heat & Power Company and assumed the management of the property.

MR. W. N. STEVENS, for some time on the engineering staff of the Rapid Transit Subway Company, has accepted a position on the staff of J. G. White & Co., New York. Mr. Stevens is widely experienced in the design and construction of important power plants.

MR. CHARLES W. CROSS, formerly of the staff of the Roberts & Abbott Company, Cleveland, Ohio, and later the engineer of the Eastern Ohio Traction Company, has accepted a position with the Cleveland branch office of the Crocker-Wheeler Company.

MR. A. W. WYCKOFF has been appointed district manager for the National Electric Company at Pittsburg, Pa. Mr. Wyckoff has many friends in the Pittsburg section, having represented the Bullock Company there very effectively prior to the present appointment.

MR. H. S. REYNOLDS, who represented Stone & Webster's interests in Columbus, Ga., for several years, has severed his connection with that firm to accept a position on the operating staff of J. G. White & Co. His headquarters will be at the firm's New York offices.

MR. C. A. MORENO, for some time past chief engineer of the United Railways Company, St. Louis, Mo., has resigned that position to engage in consulting engineering on his own account. He was presented with a handsome silver dinner service last month by the officials of the company on the occasion of his relinquishment of his position.

MR. FREDERIC NICHOLS recently delivered an extremely interesting address before the Em-

pire Club, Toronto, Can., on "Niagara's Power, Past, Present and Prospective." The address has been reprinted in pamphlet form in very elegant style.

MR. JOHN BLAIR MACAFEE, the well-known Philadelphia engineer, has added to his other interests the engineering supervision of the work of the York (Pa.) Intramural Street Railway Company, York Railway & Electric Company; York, Hanover & Western Street Railway Company, and the King Street & Carlisle Avenue Street Railway Company.

MR. E. J. PIETZCKER, who has been a member of the Standard Underground Cable Company's Western Sales Department for several years, has been appointed manager of the company's new office at St. Louis, Mo. Mr. Pietzcker has had many years of experience in the wire and cable business and has many friends in the St. Louis territory who are glad to welcome him back.

MR. W. F. GRADOLPH, formerly chief engineer for the Central Telephone & Electric Company, St. Louis, has resigned that position to engage in consulting and contracting engineering. He has established an office at 2908 St. Vincent Avenue, St. Louis, and while he will make a specialty of telephone work, he will not restrict his field to this branch but will undertake contracts for electric lighting and power equipment, etc.

MR. CHARLES H. BAKER, who has been the president and chief engineer of the Snoqualmie Falls Power Company, Seattle, Wash., ever since he founded it six years ago, has sold out his interest in the company and retired from its management to take a thorough rest. He contemplates a trip to China and Japan chiefly for pleasure, but expects to keep an eye open for possibilities in the way of hydraulic-electric enterprises.

TRADE PUBLICATIONS.

REMOTE-CONTROL RHEOSTATS. General Electric Company.—Bulletin 4398, containing an illustrated description of field-circuit rheostats for operation from a distance.

AUTOMATIC BOILER FURNACES. The Model Stoker Company, Dayton, Ohio.—A catalogue of standard size, describing the new Model automatic stoker manufactured by this company.

MACHINERY AND TOOLS. Brown & Sharpe Manufacturing Company, Providence, R. I.—This is the 1905 edition of the well-known pocket-size catalogue which this company has issued for many years past.

POLYPHASE WATTMETERS. Fort Wayne Electric Works, Fort Wayne, Ind.—This is bulletin No. 1061, containing an illustrated description of the type K polyphase induction watt-hour-meter manufactured by this company.

N. L. C. CENTRAL STATION BULLETIN. Nernst Lamp Company, Pittsburg, Pa.—A monthly publication in bulletin form, the object of which is to familiarize central station men with the merits and possibilities of Nernst lamps.

ELECTRICAL LABORATORY APPARATUS. C. H. Thordarson, Chicago.—A catalogue of convenient size, containing illustrated descriptions of experimental apparatus, high-potential transformers, special spark and impedance coils, etc.

TELEPHONE APPARATUS. The Kusel & Kusel Automatic Switchboard Telephone Manufacturing Company, Chicago.—A catalogue of folio size, containing illustrations of telephone switchboards, instruments and switchboard fittings.

PIPE AND BOILER COVERINGS. The H. W. Johns-Manville Company, New York.—A nicely-executed vest pocket pamphlet, containing illustrations and brief descriptions of the well-known line of pipe and boiler coverings manufactured by this company.

PURCHASERS OF IDEAL ENGINES. A. L. Ide & Sons, Springfield, Ill.—An astonishingly long list of industrial establishments, mines, central lighting stations, hotels, distilleries, street railways and other enterprises using the well-known Ideal automatic engine.

CRANE MOTORS. Westinghouse Electric & Manufacturing Company.—This is circular No. 1097, containing a well-illustrated description of the Westinghouse type K direct-current series-wound motors for crane, hoisting and similar classes of service.

USEFUL LIGHT. The Shelby Electric Company, Shelby, Ohio.—A catalogue containing illustrated descriptions of the well-known line of Shelby lamps, with the usual forcible arguments in favor of the downward distribution peculiar to the standard Shelby lamp.

THE PIGEON HOLE. The Peerless Electric Company, Warren, Ohio.—A folder printed on light cardboard and devoted to the excellent line of stationary motors built by this company. "The Pigeon Hole" is issued monthly, each number relating to some product of the Peerless Company.

TELEPHONE APPARATUS. The Wesco Supply Company, St. Louis, Mo.—This is bulletin No. 61, devoted to the Wesco "Express" switchboard and parts, and bulletin No. 62, containing illustrated descriptions and price-lists of telephone instruments, magnetos, complete sets, and parts.

STORAGE BATTERIES. The Electric Storage Battery Company, Philadelphia, Pa.—Price lists "A," devoted to the "Chloride" accumulator, and "X," devoted to the "Exide" battery. The catalogues have been thoroughly revised and brought up to date, and are handsomely executed.

ELECTRICAL SPECIALTIES. The Appleton Electric Company, Chicago.—This is catalogue No. 2, of convenient pocket size, devoted to electric lighting and telephone specialties and supplies. The telephone specialties include a line of new lightning arresters of the combined carbon and fuse type.

STEAM TURBINES. The Westinghouse Machine Company.—A handsomely-executed book of standard catalogue size, containing a profusely illustrated description of the Westinghouse-Parsons turbine in its latest development, together with some interesting records of efficiency tests made on turbines of different sizes.

ELECTRIC STORAGE BATTERIES. National Battery Company, Buffalo, N. Y.—Catalogue No. 13, in which are described and illustrated the National battery for electric vehicle service, and catalogue No. 14, devoted to the company's standard stationary type of accumulator. The catalogues are both of standard size and handsomely executed.

WATTMETERS AND HOW TO READ THEM. Westinghouse Electric & Manufacturing Company.—This is designated Folder No. 4032, but is in fact a well-executed pamphlet of vest-pocket size, containing very clear instructions for the reading of watt-hour-meter dials, together with illustrations of Westinghouse Type A and Type B watt-hour-meters.

AUTOMOBILE CHARGING EQUIPMENTS. General Electric Company.—This is bulletin No. 4402, containing an illustrated description of very compact switchboards for use in charging automobile storage batteries. To the switchboard which has been heretofore used the company has added a mercury arc rectifier with auxiliary appliances, which, of course, allows the charging to be done from an alternating-current circuit.

THE STANDARD MOTORS AND GENERATORS. The Robbins & Meyers Company, Springfield, Ohio.—This is price-list P-20, containing illustrations, tabulated data and other information concerning the well-known line of Standard dynamos and motors built by this company. The catalogue is of standard size, well executed, and its contents are most conveniently arranged. Having an unusually large number of frames, the company is able to give several ratings at each output, so that the purchaser has a wide range of choice.

BUSINESS NEWS.

HENRY C. TULLEY, St. Louis, Mo., has issued a booklet relating to his Engineers' Handbook, which is entitled "A Business Proposition."

THE A. D. GRANGER COMPANY, New York, has established a branch office at Pittsburg under the management of E. W. Bentley, with headquarters in the Bessemer Building.

LAGONDA MANUFACTURING COMPANY, Springfield, Ohio, announces that a large order was recently received through its New York office for a shipment of its boiler-tube cleaners to go to Tokio, Japan.

STANDARD UNDERGROUND CABLE COMPANY, Pittsburg, Pa., has established a branch office at 521 Security Building, St. Louis, Mo., which will have charge of all the company's business in the southern and south-western territory.

LIONAIS & POULIN is the style of a new firm of electrical contractors which has established headquarters at 242 St. James Street, Montreal. The firm makes a specialty of armored and decorative work, but takes contracts and does repairs of all kinds.

THE ROBBINS & MYERS COMPANY, Springfield, Ohio, has received from the St. Louis Exposition authorities the highest awards in their classes for its well-known and widely appreciated dynamos, stationary motors and ceiling and desk fan-motors.

SPRANLEY & REED, of New Orleans, have been appointed district representatives of the National Electric Company, Milwaukee. The firm has had wide experience in the electrical field in and around New Orleans, having been formerly the representatives of the Bullock Company.

EMPIRE STATE DRY BATTERY COMPANY, New York, is the latest concern to enter the field of dry battery manufacturing. The company has established headquarters at 70-76 Fulton Street, where it has a well-equipped factory and has already inaugurated a very satisfactory business.

THE STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY, Chicago, reports that it has just completed one of the finest toll boards for the U. S. Telephone Company for use at Toledo, Ohio, that it has ever turned out. The board comprises five sections of three operators' positions each.

THE TRUMBULL ELECTRIC MANUFACTURING COMPANY, Plainville, Conn., has found it necessary on account of largely increasing business to raise its capital stock to $100,000, and will build a four-story brick factory during the present year. It is the intention of the company to make a specialty of panel and switchboard work.

THE PELTON WATER-WHEEL COMPANY, of San Francisco, reports a brisk business in its line, a large number of sales having been made recently to electric power companies operating steam plants; the Pelton wheels sold to these companies are to be used in supplementary stations operated in parallel with the existing steam stations.

THE NATIONAL CARBON COMPANY, Cleveland, Ohio, naturally feels proud of its award from the St. Louis Exposition. The grand prize given the company by the Jury of Awards covers its complete line of carbon products, including Columbia carbons, Columbia batteries, motor and generator brushes, large smelting electrodes, and carbons for electrochemical work.

CHASE-SHAWMUT COMPANY, Newburyport, Mass., announces that the Shawmut soldered rail-bond is now handled in Philadelphia and vicinity by H. F. Sanville & Co., and that the complete Chase-Shawmut line is handled, in their respective districts, by William S. Brown, New York; Thos. G. Grier Company, Chicago; L. F. Mahler Company, St. Louis; Spranley & Reed, New Orleans, and John R. Cole Company, San Francisco.

THE WESTINGHOUSE ELECTRIC & MFG. COMPANY has closed a contract with the United Railways & Electric Company, Baltimore, Md., for a 5000-kw. three-phase alternator to be direct-driven by a steam engine and to operate in parallel with the five 2000-kw. machines which the company recently installed in the Pratt Street station. The big machine will run at 94 r.p.m. and give 13,000 volts at 25 cycles.

THE ELECTRIC CONTROLLER & SUPPLY COMPANY, Cleveland, Ohio, reports the most gratifying success for its new lifting magnet

designed to handle pig iron, small billets, scrap iron or steel, etc. This magnet is adapted to hang on the ordinary hook of a traveling crane, and is simply lowered into the pile of pigs or billets, energized, and lifted, carrying with it as many pieces of the iron as can get into effective contact with it.

CENTRAL ELECTRIC COMPANY, Chicago, announces that notwithstanding the disastrous fire on February 11 which completely destroyed its offices and warehouse, it has not by any means been put out of business. Temporary headquarters have been established at 209 East Jackson Boulevard, and by the time this announcement reaches the eye of the reader the company will doubtless be in position to give prompt attention to all orders.

B. S. BARNARD & COMPANY is the name of a newly incorporated concern with offices at 39-41 Cortlandt Street, New York. The officers of the company are B. S. Barnard, president; W. H. Barnard, vice-president and treasurer; L. Bancroft, secretary, and A. Dunlop, manager of the electrical department. The company will represent the Peerless Electric Company, Warren Electric & Specialty Company, Colonial Fan & Motor Company, Colonial Electric Company, Boston & Sandwich Glass Company and the Hammond Manufacturing Company.

HARRISBURG FOUNDRY & MACHINE WORKS, Harrisburg, Pa., has just issued a reprint in facsimile of an extensive article which was published by *The Engineer*, of London, and describes the Fleming engine exhibited at the recent St. Louis Exposition. The engine was the latest type of four-valve compound and was used at the Exposition in connection with the Intramural Railway. It received a gold medal and diploma, the highest award in its class, from the International Jury.

QUAKER CITY RUBBER COMPANY, Philadelphia, Pa., is receiving constantly the most flattering testimonials to the merits of its "P.P.P." rod packing. Among recent letters of this character is one from the president of a water company in Kentucky who states that after a great deal of trouble with gritty water, during which all sorts of packings were tried his company put in "P.P.P." packing at a time "when the water was at its worst." The result was that the packing lasted four times as long in the unusually gritty water as flax packing did in clear water, and greatly reduced the cutting due to grit.

ALLIS-CHALMERS COMPANY has adopted the policy of having each of its district offices represent the company's entire lines of manufacture. This has involved the establishing of a number of new branch offices, the lines being so extensive and diversified as to necessitate representation in many places where one or two classes of machinery alone would not justify maintaining local headquarters. The existing branch offices have also undergone changes under the new order of things. At St. Louis, a branch office has been established in the Chemical Building under the management of Mr. H. P. Hill, formerly manager of the local Bullock office; the latter has been consolidated with the new office. At Cleveland, the same change has been made, Mr. Franklin Wharton, the former Bullock manager, being now in charge of all interests. At Pittsburg, Mr. H. Wiedeman, who has represented the Allis-Chalmers engines, etc., there for several years, is now in charge of the complete establishment covering all lines. This is also true of Mr. Geo. W. Mattison, in Kansas City. At Buffalo, N. Y., a new office has been established temporarily in the Ellicott Square Building under the management of Mr. Geo. W. Pulver, who was for several years with the Syracuse office of the Westinghouse Electric & Mfg. Company.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

SYLACAUGA.—Bonds to the amount of $24,000 have been sold, the proceeds to be used for the construction of an electric light plant and water works.

GOODWATER.—Arthur Salmon has secured a franchise to install an electric light plant in Goodwater, and hopes to have the town lighted by May 1.

BIRMINGHAM.—This year will be marked in the history of the Birmingham Railway, Light & Power Company as one of expansion. Extensive improvements have been planned by the management, which will include important changes at the present power house at an estimated cost of $150,000, $50,000 worth of improvements to the gas system, the erection of a new power house and passenger station at Bessemer and of viaducts over the railroads here, and a large increase in its rolling stock. At the power house mechanical stokers will be installed, besides other devices for the economy of coal and the saving of smoke. It is expected that these extensive changes will consume a year or more.

ARIZONA.

PRESCOTT.—A big electric power and transmission plant is to be established at Parker's Butte, about 75 miles from Prescott, by the Verde Water & Power Company. It is proposed to develop about 20,000 horse-power which will be transmitted to Prescott and other towns of the territory. It is also planned to supply many mines with power.

ARKANSAS.

SILOAM SPRINGS.—The Siloam Springs Railroad, Power & Light Company has been incorporated with a capital of $500,000.

POCAHONTAS.—S. C. Dowell, of Walnut Ridge, states that he expects soon to erect a $25,000 electric plant in this city.

MADILL.—Plans are under discussion for the establishment of an electric light plant here, but nothing definite has been decided as yet.

ENGLAND.—The contract for the erection of the electric light plant for England has been let to the Martin-Reynolds Electric Company, of Little Rock. The plant is to be ready for operation in ninety days and will run at first fourteen street arc lights.

CARLISLE.—An electric light system is to be installed here in the near future, it is said, but no information has been received concerning the details of the enterprise, and whether a local plant is to be established or the current supplied from an outside source is not known at the present writing.

CALIFORNIA.

SAN JOSE.—The National Park Electric Company, with a capital of $250,000, has been incorporated by J. J. Inman, M. E. Page, W. H. Baugh, and others.

SANTA BARBARA.—Articles of incorporation have been filed for the Merchants' Mutual Light & Power Company by John T. Johnston, C. H. Frink and J. H. Burson.

OAKLAND.—Press reports state that an ordinance is to be introduced in the City Council providing for the placing of all wires underground in the business district within the next three years.

EUREKA.—Application has been made by the North Mountain Power Company for a franchise to construct and maintain an electrical transmission line over certain public roads and highways of Humboldt County.

FRESNO.—The San Joaquin Power Company has decided to begin at once the construction of another power plant near the Crane Valley reservoir, with a capacity of 3500 horse-power. William G. Kerckhoff, of Los Angeles, is president of the company.

MARYSVILLE.—The Bay Counties Power Company, which is controlled by the California Gas & Electric Corporation, of San Francisco, is making preparations to erect a new power plant and construct a transmission line along the Yuba River from Smartsville to this city.

SAN FRANCISCO.—The San Mateo Power Company has filed articles of incorporation setting forth its purpose to manufacture gas and electricity for heat, light and power and stating its capital stock to be $1,000,000. Among the directors named are: Walter J. McLean, Henry Bostwick and Leo H. Susman.

LOS ANGELES.—Members of the Broadway Improvement Association have formed a company to establish an independent lighting plant to furnish power for lighting the 135 clusters of arc lights along Broadway. Stock to the amount of $100,000 has been subscribed and preparations are already under way for the establishment of the plant in the shortest possible time. F. W. Blanchard, Maj. J. H. Norton, J. M. Schneider, Avery McCarthy, N. Bonfilio and C. W. Fleming are among those interested in the project.

SAN FRANCISCO.—It is stated that the California Gas & Electric Corporation has purchased the plants of the South Yuba Water Company and the Central California Electric Company. The company has also purchased property across the line in San Mateo County on the bay shore near the Seven-Mile House. It is the intention of the company to put up a plant to furnish electric power to the United Railroads of San Francisco and to other parties as well. It is understood that the engines for the proposed plant have been ordered.

MARYSVILLE.—Plans are being developed for electrical power in Yuba County which may rival the Colgate plant of the Bay Counties Power Company. There has been filed in Yuba County a notice of location of a claim to 100,000 inches of the water of the Yuba River, the same to be diverted at the point near Smartsville known as The Narrows by means of a dam which will about cost $800,000. While the names of James O'Brien, of Smartsville, and J. E. Ebert and Lon H. Mitchell appear in the notice as the locators, it is understood that the capital to further the scheme will be provided by the Marysville & Nevada Power Company. From The Narrows the water is to be conducted by means of a ditch 40 feet wide on the bottom, 80 feet wide on top, and 10 feet deep, along the north bank of the river to a point on the Forbes ranch, thence along the north bank of Dry Creek to the Sicard Flat crossing, where it is to be used for the generation of electric power. Below this point the water is to be again taken up and carried north to Honcut Creek for irrigation purposes. All the surplus water is to be returned to the Yuba River through Dry Creek. In order to secure the stone and timber for the proposed dam at The Narrows the same locators have taken up a tract of land in section 22, naming it "The Narrows Placer Mining Claim."

COLORADO.

RIFLE.—A. L. Hackenberger, of Dallas, Tex., is making arrangements to construct an electric light plant in this city at a probable cost of $25,000.

DENVER.—Improvements which will cost approximately $300,000 are to be made by the Denver Gas & Electric Company, the work to begin at once. A new building will be erected at a cost of $100,000, while other improvements and extensions to the gas mains will aggregate $200,000 more. In proportion to size, Denver now stands second among the light consuming cities of the United States, Grand Rapids, Mich., being ahead of it by virtue of its numerous furniture factories. The increased use of electricity has been a large factor in the growth of the Denver plant.

Eleven factories and lumber mills along the Rio Grande tracks south to First Street have decided to abandon steam motive power for electricity and a new electric transmission line has been completed to Golden for operating dredgers in that section.

GREELEY.—The Greeley Gas & Electric Company has been incorporated with a capital of $50,000, by Charles E. Ramsay, Martin A. Bunker, Burton D. Sanborn and others.

COLORADO SPRINGS.—At the annual meeting of the Colorado Springs Electric Company, held January 31, officers were elected as follows: President, W. A. Otis; first vice-president, George R. Buckman, both of Colorado Springs; second vice-president, S. R. Bertron, of New York City; secretary and treasurer, Irving W. Bonright, Colorado Springs; assistant secretaries and treasurers, F. W. Stehr, of Colorado Springs, and Murray Dodge, of New York City; general manager, George B. Tripp, of Colorado Springs.

CONNECTICUT.

WILLIMANTIC.—The gas plant and the electric station of the Willimantic Gas & Electric Light Company have been thorougly remodelled under the supervision of Arthur E. Jackman, engineer, of Boston, who has been retained as superintendent of the works.

GEORGIA.

ROME.—The City Council will petition the State Legislature for permission to construct and operate a municipal electric light plant.

CAIRO.—The Clerk of Council writes that the citizens have voted to issue $15,000 bonds for the construction of water works and an electric light plant.

AUGUSTA.—Recent advices state that the Augusta-Aiken Railway & Electric Company is installing in its plant a 250-kw. two-phase Bullock alternator.

CONYERS.—W. G. Flake, president of the Panola Light & Power Company, writes that the company contemplates extending its lines to Covington. The extension will cost between $15,000 and $20,000.

IDAHO.

EMMETT.—The electric light plant of J. H. Forbes is to be taken over by a stock company according to local reports.

LEWISTON.—C. A. Weyerhauser, William Deary and others are interested in a project to erect a power plant on the Clear Water River near this city.

ILLINOIS.

CHICAGO.—The Edison Light Company has been incorporated by Clayton R. Taylor and Percy B. Eckhart, with a capital of $2500.

FAIRBURY.—The Fairbury Electric Light & Power Company announces an increase in its capital stock of $18,000, which brings its capitalization up to $30,000.

WAUKEGAN.—A special committee has been appointed to investigate the feasibility of establishing a city electric light plant and to devise means of securing a better water supply.

MONMOUTH.—The Monmouth Gas & Electric Company is preparing plans for various improvements at its plants, among which are included important changes to the electric light plant.

BLUFFS.—Reports state that Henry Knoppel, secretary of the Bluffs Exchange Telephone Company, together with Fred Brockhouse, expects to establish an electric light plant here in the spring.

EAST ST. LOUIS.—The East St. Louis Consumers' Electric Light, Power & Heat Company has been incorporated with a capital stock of $75,000 by H. J. Dehaan, Fred W. Zegenhein and others.

EAST ST. LOUIS.—The St. Clair Light & Power Company has been incorporated for the purpose of furnishing light and power. The capital is $75,000 and C. L. Gray and H. C. Bernard are among the incorporators.

DANVILLE.—The Danville Street Railway & Light Company is about to put in a 1500-h.p. engine and a 60-cycle alternator to supply all of the alternating-current lighting in Danville. Most of the transformers have been changed from 130 to 60-cycle types already.

ELGIN.—At a recent stockholders meeting of the Elgin Hydraulic Company plans were discussed for the formation of a $100,000 concern to establish a hydro-electric power plant. If the project is consummated, an auxiliary steam plant will be installed for service during low-water periods.

DIXON.—The titles to and ownership in the dam and hydraulic plant of the Dixon Power & Lighting Company are said to have been acquired by the Lee County Lighting Company, of which H. C. Higgins is the manager. The consideration in the transaction is stated as $200,000.

AURORA.—A company, known as the Aurora Manufacturing & Lighting Company, has been incorporated for the purpose of engaging in a general manufacturing business and furnishing electricity for light and power. The company is capitalized at $12,000, and Percy G. Lincoln and F. W. Detray are among those interested in the concern.

AURORA.—The Western United Gas & Electric Company has been formally organized in this city with a capital of $5,000,000. This is understood to be a reorganization of the Fox River Light, Heat & Power Company, operating on a capital of $500,000, and it is expected that the new concern will take over and consolidate several large plants.

JERSEYVILLE.—The Jerseyville Illuminating Company, which was recently organized, has decided to take over the plant of the Jerseyville Light, Heat & Power Company which now operates the lighting plant of the city. The members of the selling company are practically the same as the ones comprising the new concern. The illuminating company also decided to erect a hot-water heating plant and will run both a day and night circuit for lighting purposes, and also for furnishing day power. The proposals to increase the capital stock to $100,000 and also to remove the power plant from its present location at Pearl and Lafayette streets to a point near the Chicago, Peoria & St. Louis Railway station were also considered. These will be decided at a later stockholders' meeting in Jerseyville.

LOCKPORT.—Proposals for constructing the power house of the Lockport power development near Lockport, Illinois, on the extension of the Main Drainage Channel of the Sanitary District of Chicago, will be received by the Clerk of the Sanitary District at Room 1110 Security Building, Chicago, Ill., until April 12. The power house is to be a concrete structure about 160 feet wide, 386 feet long and 100 feet in height. It is to contain 9 turbine chambers with bulkheads designed for a working head of 34 feet of water, a generator room 62 feet by 359 feet and offices 20 feet by 62 feet. The work for which bids are invited includes excavating the site, supplying all materials for the sub-structure and superstructure of the power house, and erecting same complete, according to plans and specifications furnished by the Sanitary District of Chicago.

INDIANA.

NOBLESVILLE.—The City Council has granted to the G. W. Heinzman Company, of this city, a franchise for the city lighting.

MUNCIE.—William F. Warner has petitioned the City Council for a franchise to construct and maintain an electric light plant in Muncie.

TERRE HAUTE.—The power plant of the Terre Haute Traction & Power Company was recently destroyed by fire. The amount of the loss has not been ascertained.

FLORA.—At a recent meeting of the Town Council a franchise was granted to David Milles for an electric light plant. The contract calls for 15 arc lights at $80 each per year.

HUNTINGTON.—This city seems to have been very successful in the management of its municipal lighting plant. One hundred and four lamps are in use, and on the basis of cost for the months of September, October, November and December, the cost per lamp per year is $43.14.

SHIRLEY.—Late advices are to the effect that bids will be received about May 1 for the construction of water works and an electric light plant to cost from $15,000 to $25,000. All communications in reference to the matter should be addressed to B. T. Martindale, secretary of the Commercial Club.

IOWA.

SIOUX CITY.—A charter has been granted to Tilden & McRoberts, of Chicago, Ill., for a lighting, heating and power plant. Under the terms of the franchise, $100,000 must be expended within a year.

KEOKUK.—The U. S. Senate has passed a bill authorizing the Keokuk & Hamilton Water Power Company to construct a dam across the Mississippi River from Keokuk to Hamilton, Ill. It is estimated that the cost of the dam, lock and electric power plant that will be installed will be about $5,000,000. The promoters hope to furnish power not only to Keokuk and Hamilton, but to various cities within a radius of 70 to 100 miles. The company is required to build a dam and put in locks sufficient for the present commerce of the river, and to furnish the government drydock facilities. Five years are allowed for the company to begin the work, and it must be completed in ten years.

WATERLOO.—The Peterson Heat, Light & Power Company, of Des Moines, has petitioned for a franchise to install its system in this city, and it is probable that the franchise will be granted. This is the first franchise sought by the company since its organization late last fall. It is a company of Des Moines men organized under a patent secured by Oscar F. Peterson on a system of heating, lighting and ventilating. The officers are: President, Oscar F. Peterson; secretary, Charles H. Baker; treasurer, Sidney A. Foster; members of the advisory board, ex-Governor Frank D. Jackson, Charles H. Austin, W. G. Dumont, J. H. Dusenberry, W. M. Barnes and C. L. Nourse. It is the plan of the company to sell stock to a certain amount in each of the cities where a plant is installed, thus giving a local interest to each plant. Officers of the company say that they expect to make their Waterloo plant a model for other plants which they hope to install in the other cities of the State. The territory east of the Mississippi has been sold to Eastern parties who are now arranging to build municipal plants during the coming summer.

KANSAS.

INMAN.—A lighting franchise has been granted to A. S. Grosvenor by the City Council.

LACROSSE.—The question of issuing $25,000 light and water bonds is reported to be under discussion here.

PITTSBURG.—A franchise to establish an electric light plant is reported to have been granted to Morris Cliggitt.

COFFEYVILLE.—It is stated that the contracts for the equipment of the proposed municipal electric light plant have been awarded.

WAVERLY.—W. H. Williams, City Clerk, writes that Burns & McDonnell, of Kansas City, Mo., are the engineers for the construction of water works and an electric light plant. The work will probably cost $15,000.

KENTUCKY.

COVINGTON.—The City Council has engaged T. J. Creaghead, engineer, to investigate and report upon the cost of the proposed municipal electric light plant.

HARTFORD.—The Kentucky Light & Power Company has in course of construction a new lighting plant, the work being in charge of J. W. Hale, of this city.

CLOVERPORT.—A. L. Fort and Lee E. Cralle, of Louisville, together with several local capitalists, have organized a company to construct water works and an ice and electric plant for Cloverport. The new concern will be known as the Cloverport Water, Light & Ice Company.

LOUISIANA.

VIDALIA.—J. W. Wiggins, manager of the Vidalia Light & Water Company, writes that work has been commenced on the construction of a

water works system and a combined electric light and ice plant. The cost of the work is estimated at $40,000.

ABBEVILLE.—George W. Summers, secretary of the Council, writes that it is proposed to construct water works, an electric light plant and sewerage system. The citizens will shortly vote on the question of issuing $45,000 bonds for the purpose.

PLAQUEMINE.—A charter has been granted to the Plaquemine Electric Light & Power Company, having a capital stock of $30,000. It was organized to install a system of electric lights for the city, with J. H. Savage, M. Dick and V. M. Barber as directors.

SHREVEPORT.—The bursting of a fly-wheel in the electric light plant recently partially wrecked the establishment and left the city in darkness until the damage could be repaired. The present city lighting contract will expire shortly and bids are wanted April 11 for lighting the city for periods of five and ten years. Address C. G. Rives, comptroller.

MAINE.

HOULTON.—The Houlton Electric Light & Power Company has been organized for the purpose of generating and supplying electricity for heating and lighting. The company's capital stock is $10,000 and the incorporators are Hudson T. Frisbie and Walter P. Mansur, of this city.

WATERVILLE.—A petition has been presented to the Legislature to incorporate the Messalonskee Electric Company, by Harvey D. Eaton, Walter S. Wyman, John N. Webber, and others. The purpose of the company is to generate and distribute electricity in this city. Oakland, Fairfield, Benton and Winslow. The capital is stated to be $250,000.

BANGOR.—Recent reports are to the effect that the Maine & New Brunswick Electric Power Company will in the early spring begin the development of its property at Aroostook Falls, and it is understood that before the end of the year the company proposes to have in operation a plant to supply electric light and power to a number of towns in Maine and New Brunswick. Arthur G. Gould, of Presque Isle, is said to be interested in the project.

MARYLAND.

CHESTERTOWN.—Mr. D. S. Pindell, of Saulte Ste. Marie, Mich., who has been granted a franchise for the construction of an electric plant and lighting system, writes that the franchise covers a period of forty years and that work on the plant will commence at once. The cost is estimated at $30,000.

MASSACHUSETTS.

SPRINGFIELD.—The Committee on Public Lighting has given a hearing on the petition of W. S. Kelley to revive the corporate powers and to confirm the acts of the Hoosac Electric Power Company. It is proposed to distribute power to Monroe, Florida, Clarksburg, Williamstown, Adams and North Adams.

MILLIS.—The new electric light system, which has been in course of construction here by the Medfield Electric Light & Power Company, has been completed. Over 125 incandescent lights of 25 candle-power each have been placed in position on the principal streets. The Selectmen have entered into a three years' contract with the company.

SHEFFIELD.—The Sheffield Light & Power Company has been granted a charter, with a capital of $5000 and the following officers: President, Samuel M. Fox; secretary and treasurer, Albert L. Barnes. These officers, with George de P. Fox and W. Taylor Day, of Great Barrington, constitute the board of directors. The company purposes furnishing light and power to the residents of Sheffield, and it is said that about fifty private consumers have been guaranteed already.

DALTON.—Recent reports are to the effect that Z. and W. M. Crane have contracted with the Pelton Water Wheel Company, New York, and the Stanley Electric Manufacturing Company, Pittsfield, Mass., for hydraulic and electric apparatus for a water power plant to be installed at the stone mill in the Renfrew District, to supply electricity to the Dalton Mills and other industries. The plant will probably cost about $75,000.

MICHIGAN.

SAGINAW.—A municipal lighting plant for this city is under discussion by the Council.

GROSSE POINTE FARMS.—The Village Council is considering the installation of an electric light plant.

DE WITT.—Arrangements have been made with the Lansing & Suburban Traction Company to furnish electric lights for the village.

SPRING LAKE.—The West Michigan Light & Power Company has been awarded a three-year contract to supply light to this city.

DOWAGIAC.—D. E. Connine, superintendent of the city electric light plant, writes that the plant will be remodelled at a cost of about $1400.

PONTIAC.—It is said that A. Jacobs, of Detroit, has been here recently, looking over the ground with a view to establishing a gas and electric light plant in the near future.

MARQUETTE.—It has been decided to change the open-arc system, now in use in this city, to the enclosed-arc alternating-current lamp system, and a contract has been awarded to the Westinghouse Electric & Manufacturing Company for 125 alternating-current street lamps, two 75-lamp converters, switchboard panel and other equipment necessary to make the change. The contract amounts to about $3300.

MINNESOTA.

HIBBING.—The Hibbing Water, Light & Power Company has been incorporated by D. D. Crowley, H. A. Liedel and John W. Day to establish a water, light and power plant. The capital is $50,000.

ROYALTON.—Royalton is soon to commence the installation of an electric light plant, it having just floated $10,000 bonds for this purpose. The bonds brought $10,371, with ten bidders in the field.

STILLWATER.—The Stillwater Gas & Electric Company has filed amended articles of incorporation in order to raise money to pay off the old bonded indebtedness, construct a new gas works in Stillwater, and to take over the property of the Apple River Power Company, which latter concern generates electricity for this city.

MISSISSIPPI.

SEMINARY.—The Mason Lumber Company, of Platt Station, has decided to construct an electric light plant, and will furnish lights for Seminary.

LAUREL.—The electric light and power plant of the Laurel Improvement Company was recently destroyed by fire, entailing a loss of $14,000, $8000 of which was covered by insurance. The fire started at the switchboard and is thought to have been due to defective insulation. The city is in darkness and many small industries which were operated by electric power were forced to close down temporarily. The company will rebuild at once on a larger scale.

MISSOURI.

LEXINGTON.—The Lexington Gas & Electric Company has been incorporated.

HARLEM.—The Henry Light, Power & Manufacturing Company has been incorporated at this point.

MADISON.—Local capitalists are agitating a project to operate an electric light plant in connection with the mill.

STURGEON.—The recent special election resulted in the carrying of a proposition to put in an electric light plant.

INDEPENDENCE.—The light plant of this city was shut down the night of February 14 on account of a coal famine.

HIGBEE.—The Higbee Electric Light, Heat & Power Company has authorized W. K. Falmer, of Kansas City, to prepare plans and specifications for and superintend the construction of an electric light plant which it is proposed to establish here.

SEDALIA.—Joseph McWilliams & Co., of Louisville, Ky., have been selected by the Sedalia Water, Gas & Electric Company to prepare plans and specifications for a new central power station and to erect the same, complete with all machinery and apparatus to operate the street railway and waterworks and to furnish current for the city and commercial lighting. The cost of the plant is estimated at about $145,000.

ST. LOUIS.—The sale of the St. Louis syndicate's interest in the Union Electric Light & Power Company and the Laclede Gaslight Company to the North American Company, has been officially confirmed by Julius S. Walsh, president of the Union concern. It is announced that the syndicate got a little less than $3,000,000 worth of North American stock in exchange for its Laclede and Union stock of $6,000,000 par value. The Mississippi Valley Trust Company will act as agent of the North American in taking up the stock sold and issuing the new North American stock to the members of the syndicate. Several of the St. Louis capitalists are to be taken into the North American board of directors.

MONTANA.

NORRIS.—Thomas A. Ferguson writes that work will begin as soon as weather will permit on the construction of a power plant.

FORSYTHE.—The Council has entered into a contract with J. E. Edwards to light the town with electricity for a period of twenty years.

FORT BENTON.—The Benton Electric Light Company has been incorporated at Fort Benton with a capital stock of $15,000. The incorporators are John Harris, W. K. Harbor, Charles Lepley, John V. Carroll, C. H. Evers and L. D. Sharp. The company will build a hydro-electric plant for lighting the town.

NEBRASKA.

EDGAR.—The electric light plant, for which a franchise was recently granted to Keefe & Larkin, has been completed and is in operation.

NEW JERSEY.

HIGHLANDS.—G. W. Hardy, Borough Clerk, writes that it is proposed to construct water works and an electric light plant at a cost of $25,000. No engineer has been selected, however, and the question has not yet been voted upon.

RAHWAY.—At a recent meeting of the stockholders of the Carteret Electric Light, Heat & Power Company, it was decided to sell the stock to the Public Service Corporation. The par value of the stock is $100, and the Public Service Corporation paid $150 for it, giving a bond issue in payment.

LUMBERTON.—George F. Reid, J. M. Harrison, Walter M. Voorhees, Henry Conrow and Moses S. Watson, all of this city, have organized the Lumberton Light, Water & Sewage Company, a corporation with an authorized capital of $50,000, which will be used in the erection of lighting and water plants, and the installation of a sewer system for the town.

METUCHEN.—The Metuchen Gas & Electric Light Company has been organized with a capital of $50,000. The president is Patrick Convery; secretary, Robert Carson; treasurer, John W. Whelan, of Elizabeth; directors, A. F. Rittenmeyer, Patrick Convery, Robert Carson and L. D. Johnson. The new company has begun the work of laying gas mains through Raritan Township, and will erect a plant here at once.

NEW MEXICO.

LAS CRUCES.—The Las Cruces Electric Light & Ice Company has been incorporated with a capital stock of $50,000. Among those interested in the company are Ben L. Berkley, Joseph Wilkinson, of El Paso; Theodore Rouault and Herbert B. Holt, of this city.

NEW YORK.

HOLLY.—Reports state that the Albion Power Company will purchase the municipal electric light plant here, and will in the future furnish the town with electricity for lighting and heating purposes.

CAMDEN.—It is understood that this village has appropriated $40,000 for the construction of a municipal electric light plant.

AUGUSTA.—M. H. Simmons is president of the People's Light & Heat Company, which was recently incorporated with a capital of $300,000.

WATKINS.—The plant of the Watkins Consolidated Gas & Electric Company was burned on February 3. Watkins will be in darkness until a new plant can be erected.

NEW YORK CITY.—The incorporation is reported of the Cremo Light Company, with a capital of $100,000. Luther E. Hartley and J. I. Tilton are among the incorporators.

KIRKLAND.—C. B. Rogers, of Utica, and Joseph Rudd and S. J. Saunders, of Clinton, form the board of directors of the newly-organized College Hill Electric Light Company, having a capital of $5,000.

ALBANY.—The State River Commission has under consideration plans for harnessing Sacandaga, Racquette and Black rivers in the Adirondacks for the generation of electric power. H. A. Van Alstyne, State Engineer, is on the commission.

CANASTOTA.—The business men of this village seem to be in favor of establishing a municipal electric light and power plant, and have appointed a committee, with E. Saltsman as chairman, to obtain specifications, plans and estimates for the required plant.

SARANAC LAKE.—The Saranac Lake Light, Heat & Power Company has transferred its interests to the Paul Smith Hotel Company for $100,000. The plant will be made part of a much larger system, and the Franklin and Union Falls water power systems will be further developed.

CLINTON.—The Franklin Springs Electric Light Company has been incorporated with a capital of $5000 to furnish electricity in this city, Kirkland, New Hartford and Marshall. The directors are: Frederick DeW. Smyth and Delos DeW. Smyth, of Utica, and Edward B. Stanley, of this city.

PALMYRA.—The Palmyra Gas & Electric Light Company has been incorporated with a capital of $25,000. The company will manufacture and distribute gas and electricity for light, heat and power. The directors are named as follows: C. M. Hunt and Charles McLouth, of Palmyra; Charles A. Schwarm, of Hornellsville; George H. Shepard and William T. Morris, of Penn Yan.

ROCHESTER.—The Eastern Monroe Electric Light & Gas Company is an organization recently incorporated with a capital of $250,000, for the purpose of operating in Rochester, Irondequoit and Brighton. The directors of the new company are Henry C. Brewster, A. H. Brown, Walter A. Parce, Clarence E. Shuster. It is stated that the offices of the company will be in Rochester, while the main power plant will be located in Despatch.

TROY.—At an early meeting of the Cohoes Common Council the Hudson River Water Power Company will make application for a franchise, with the privilege of constructing a power line to Cohoes, so that it may furnish electric power to Cohoes manufactories. It is understood that the advent of the company in Cohoes is favorably looked upon by many business men, and it is likely that the company will be granted a franchise when it applies for it.

SYRACUSE.—The report is circulated that the Syracuse Lighting Company, if successful in procuring a renewal of its contract for the city lighting, will expend at once about $100,000 for improvements. The plant will be greatly enlarged, and with the increased capacity, the Lighting Company will be in a position to furnish electricity for the operation of the Syracuse & South Bay Electric Railway, the latter company having decided to purchase its power. New street arc lights will be installed, and any other improvements necessary to render the company's service adequate and complete will be made.

BUFFALO.—The Iroquois Electric Company has filed articles of incorporation, with a capitalization of $1,000,000, for the distribution of electric light, heat and power in this city and vicinity. This concern is understood to be substantially a distributing company for the Ontario Power Company, of Niagara Falls, Ont., and if the franchise asked for is granted, expects to be in position to furnish 30,000 horse-power by the 1st of July. The directors are General Francis V. Greene, Edmund Hayes, William H. Hotchkiss, George K. Birge, William H. Gratwick, R. K. Albright and Stephen M. Clement. Besides Buffalo and the Tonawandas, the company proposes to operate in the towns of Wheatfield, Pendleton and Cambria in Niagara County, the towns of Amherst, Cheektowaga, West Seneca, Clarence and Lancaster in the county of Erie, and also the villages of Lancaster, Depew and Williamsville.

NEW YORK CITY.—Mayor McClellan presented to the Board of Estimate on February 10 plans suggested by Cary T. Hutchinson, George F. Sever and Nelson P. Lewis, the committee recently apponted to consider the matter of establishing a plant for electric lighting the Boroughs of Manhattan and the Bronx. They estimate the total cost of a system capable of serving 6000 arc lamps and 250,000 16-c.p. incandescent lamps at about $4,100,000 exclusive of the cost of real estate; total cost of annual operation is $906,000.

HOLLEY.—Reports state that the Albion Power Company has made a proposition for the purchase of the municipal lighting plant here. The company offers $15,000 for the building, including the real estate, boilers, engines, electrical machinery, poles, lines and distributing system; to be paid by the bonds of the village amounting to $15,000, together with interest on those bonds from date of purchase at 4 per cent. The electric current for light, heat and power will be furnished to private consumers of Holley for a 24-hour service at the same price as it is furnished to the citizens of Albion and Brockport. The streets and public places of the village will be lighted as required, either by arc lamps or incandecent, maintaining the present service of eighty 20-c.p. lamps at $1600 a year. The company asks for a five-year contract and a permanent franchise. It is now furnishing power and light to Waterport, Albion and Brockport.

NORTH CAROLINA.

WASHINGTON.—The incorporation of the Empire Light & Power Company is reported, with a capital of $150,000. D. S. Fletcher and H. A. Smith are among the incorporators.

GRAHAM.—Plans for the new water works and electric light and ice plants for Graham are being prepared by Engineer H. A. Pressey, of Washington, D. C., and bids will probably be called for immediately.

ANDREWS.—The Andrews Light & Power Company has been incorporated, with a capital of $100,000, to construct and maintain a water works system, electric light and power plant and a telephone plant. J. Q. Barker and E. G. Henneman are largely interested in the new project.

OXFORD.—Contracts for constructing the water works and electric light and ice plants have been awarded as follows: Goulds Manufacturing Company, one 800-gal. triplex pump; Reeves Engine Company, a 90-h.p. vertical non-condensing engine; Cole Boiler Company, two 150-h.p. tubular boilers; Westinghouse Electric & Manufacturing Company, electric power station equipment; Chesapeake Construction Company, poles, lines, arc lights, etc., and incandescent light secondary circuits; York Manufacturing Company, 15-ton ice plant; Chicago Bridge & Iron Works, 100,000-gal. water tower; Glamorgan Pipe & Foundry Company, cast-iron pipe, specials and hydrants and valves.

OHIO.

LOVELAND.—The establishment of a lighting plant here is being agitated by the citizens.

CANTON.—Articles of incorporation have been filed by W. L. Davis and W. B. Weber for the Sandy Valley Light, Heat & Power Company.

BOWLING GREEN.—The County Commissioners are reported to have under consideration the construction of a lighting and heating plant.

LORAIN.—The Council has decided to purchase the necessary machinery for the installation of a small lighting plant at the pumping station.

MIAMISBURG.—Bonds to the amount of $19,000 have been sold for the purpose of merging the electric light plant and water works into one plant.

CLEVELAND.—The Cleveland Street Lighting Company was recently incorporated with a capital of $10,000, by Frank M. Gregg, A. F. Hills and others.

MAXVILLE.—Reports state that this city is soon to have a very complete modern electric light plant, but none of the particulars concerning the project have been given out as yet.

LEBANON.—The Miami Transit, Light & Power Company has been incorporated with a capital of $600,000 by F. O. Richards, M. D. Burke and others.

TOLEDO.—The contract for lighting the streets of this city for two years has been awarded to the Toledo Railway & Light Company at $83 per arc light per year.

CLEVELAND.—The National Light & Manufacturing Company has filed articles of incorporation, naming among its directors George L. Chandler, W. B. Matthews and Erwin H. Guthery. The enterprise is capitalized at $25,000.

STEUBENVILLE.—Frank S. King, City Auditor, writes that the council has under consideration the question of submitting to a vote of the people at the spring election the construction of a municipal electric light plant, to cost $180,000.

NORWALK.—Bids will be received until March 21 by the Board of Public Service for furnishing the necessary lights for a period of ten years to properly light the public places, streets, avenues and alleys, with either gas or electric lamps, or a combination of them.

HAMILTON.—The Hamilton Gas Light & Coke Company has changed its name to the Hamilton Gas & Electric Company and increased its capital to $1,000,000. The company will spend at once about $250,000 in improvements and extensions, and expects to install in the near future a new electric power plant.

MARION.—The Marion Railway, Light & Power Company plans to make important improvements in its electric light system during the coming summer, at a cost of $50,000 or $60,000. The entire overhead system will be overhauled to make it uniform. The railway system will also be improved.

SPRINGFIELD.—The interests of the Citizens' Heat, Light & Power Company, which was incorporated something less than two years ago, will be absorbed by the new concern recently incorporated under the name of the People's Heat, Light & Power Company, and capitalized at $1,500,000. John L. Zimmerman is president of the new company, and others interested are: F. M. Hagan, Albert H. Kunkle, W. W. Keifer, Walter L. Weaver, Frank Clark and Frank Torrence. It is stated that contracts will be let immediately for a modern lighting and power station, to be erected on the Jefferson Street site purchased recently. The station is to be 66 feet by 165 feet, and two stories high. It will be made of brick and steel. Unless the company can have a switch laid from the railroad, a chute will be dug from the Panhandle tracks into the basement. It is estimated that the cost of construction and equipment and laying the conduits and pipes will be about $500,000.

OKLAHOMA TERRITORY.

OKEENE.—The Okeene Ice & Light Company has been incorporated with a capital stock of $50,000.

WANETTE.—Philip Hall, of Shawnee, is said to be interested in the construction of water works and an electric light plant here.

KINGFISHER.—The Citizens' Gas Light, Heat & Power Company has been incorporated with $100,000 capital, by E. E. Hull, C. C. Roberts and J. B. Buckles.

STROUD.—A charter has been issued to the Stroud Light & Power Company, having a capital stock of $15,000 and the following stockholders: A. H. Sherwood, Lee Patrick, H. M. Jarrett and G. T. Haines, all of this city, and Sam R. Flores, of Oklahoma City.

ANADRAKO.—The Union Light & Power Company, of El Reno, has been awarded the contract for constructing an electric lighting plant to be operated in connection with the water works. The plant, it is estimated, will cost about $10,455, and is expected to be ready for operation within ninety days.

OREGON.

JACKSONVILLE.—The City Council recently granted A. E. Recunes an electric light franchise, the plant to be in operation in three months.

PRAIRIE CITY.—Dr. Carlton Faull and Alfred Curry, of Baker City, are reported to be negotiating for the purchase of the Prairie City electric light plant. If purchased, about $25,000 will be expended for improvements. They will also construct water works.

PENNSYLVANIA.

COLUMBIA.—John S. Graybill, Jr., of Lancaster, is said to be one of the incorporators of the Columbia Electric Light, Heat & Power Company, which has a capital of $10,000.

BRIDGEPORT.—The Norristown Electric Light Company, of Norristown, is said to have secured the contract for lighting the streets of this village at $70 per lamp per year.

PITTSBURG.—The People's Light & Power Company, recently organized at McKeesport, has been granted a franchise by the Select Council of Pittsburg to erect poles and string wires on all the streets.

HANOVER.—The statement was made in these columns last month that Mr. Mumper had been awarded the contract to light the streets of this borough. We are informed now, however, that Mr. Mumper was unable to produce the required bond of $5000 at the time specified by the Council, and the contract was therefore given to the Hanover Light, Heat & Power Company for the term of five years.

WEST SCRANTON.—An application is to be made to the governor for a charter for the West Scranton Light, Heat & Power Company by William T. Davies, John H. Williams, Herbert L. Taylor and others, all connected with the West Scranton bank. It is understood that the company proposes to operate principally in West Scranton.

YORK.—The papers of incorporation of the Yoe, Windsor and Dallastown Electric Light Companies, which were granted by the State Department at Harrisburg last month, have been filed in the office of Recorder Bentz. The corporations each have a capital stock of $5000, divided into 200 shares. The incorporators and directors are: Eli S. Nisly, Florin, this State; George R. Heisey, Lancaster; E. R. Heisey, Dallastown. The purpose of the companies is to furnish Dallastown, Yoe, Red Lion and the surrounding territories with light, heat and power by means of electricity generated at Red Lion, the companies having secured the old match factory at that place for their plant.

MIDDLEBURG.—George W. Wagenseller, of this city, and David Goldstein, of Pittsburg, have secured a franchise for the construction of a power plant on Middle Creek below Selinsgrove. A company will be organized with a capital stock of $50,000. The proposed site is between two mountains, the location being known as Hoover's dam. It is the company's intention to tunnel the mountain, which will require about 900 feet of excavation, giving a water pressure of about 600 horsepower. When the plant is completed electricity for lighting and power purposes will be furnished within a radius of many miles.

SOUTH CAROLINA.

BRANCHVILLE.—Advices state that bids are now being received for an electric light plant and telephone exchange to cost about $6000.

CLINTON.—Engineer Charles C. Wilson, of Columbia, writes that no date has yet been set for the opening of bids for the proposed water works and electric light plant. It was stated last month that bids would be received February 15.

CALHOUN FALLS.—Dr. S. M. Orr, of Anderson, and O. S. Sheffield, of Atlanta, are interested in developing the Savannah River power above Calhoun Falls, including Cherokee and Gregg Shoals. Joseph E. Sirrine, of Greenville, is said to have prepared the plans. The dam will be 1000 feet long, 24 feet high, and will develop 6600 horse-power.

GREENWOOD.—A. J. Sproles, superintendent of the Greenwood water and electric light plant, writes that they are in the market for quotations on the following apparatus f. o. b. Greenwood, specifications and guarantees to accompany each bid: One 180-kw. revolving field three-phase 60-cycle, 2200-volt alternating-current belted generator; one each 60 and 120-kw. revolving-armature single-phase 60-cycle 2200-volt belted generators; seventy 1200-c.p. series alternating-current arc lamps complete, out-door type; one-half gross clear inner globes extra; 48 clear outer globes extra; one 100-light constant-current transformer with two leads for two circuits, complete with meter and switchboard. Bids are desired on each generator, and the lamp outfits separately and together. No orders will be placed, however, until the Commissioners of Public Works have thoroughly canvassed all specifications, guarantees, prices, etc., in detail, which will probably be the latter part of March.

SOUTH DAKOTA.

DELL RAPIDS.—Recent local reports are to the effect that the question of municipal electric lighting is again under consideration.

MONTROSE.—Mark Donahue and P. G. Williams, of this city, are organizing a company for the purpose of establishing an electric lighting plant.

TENNESSEE.

CAMDEN.—A new electric light plant is to be installed in Camden soon. L. A. Wyatt, backed by local capital, is pushing the project.

JOHNSON CITY.—The Board of Aldermen and the Mayor have petitioned the Legislature for permission to vote and issue $250,000 bonds for the construction of water works or for the purchase of the local system, and $50,000 for the building of an electric light plant.

TEXAS.

UVALDE.—A franchise has been granted for the installation of an electric light and power plant here.

BAIRD.—The Home Telephone & Electric Company has filed articles of incorporation with a capital stock of $25,000.

GONZALES.—The Citizens' Electric Light & Power Company is reported to have doubled its capital stock recently, it amounting now to $10,000.

FORT WORTH.—F. W. Potter has petitioned the City Council for a franchise granting him the privilege of establishing an electric light and power plant.

LUFKIN.—The Lufkin Electric Light & Power Company has been incorporated by S. W. Henderson, G. F. Hackney and J. S. Henderson, and is capitalized at $30,000.

HOUSTON.—Chris L. Nielson, representing Evans, Almirall & Co., of New York City, will be in Houston for the next few months in connection with the work of reconstructing the plant of the Houston Light & Power Company, that work being now in progress.

SAN ANTONIO.—C. A. Zilker, vice-president of the Southern Ice & Cold Storage Company, of this city, is said to be interested in a plan to organize an independent electric lighting company in this city. The plant, if established, will cost probably $100,000, and will be equipped to furnish both light and power.

TEXARKANA.—H. N. Morris, president of the Shreveport Gas, Electric Light & Power Company, Shreveport, La., was here recently promoting a deal whereby the Dawes Syndicate, which owns the above mentioned company, acquires the plant at this place, the transaction involving in the neighborhood of $200,000, it is said. It is the intention of the purchasers to spend considerable money in improving the property. The officers of the Texarkana company are: President, H. N. Morris; vice-president, R. C. Dawes; secretary, J. B. Sherman.

UTAH.

HUNTSVILLE.—The citizens are considering the question of issuing bonds for the construction of a municipal lighting plant.

PARK CITY.—Henry Shields and associates are said to have secured a franchise to furnish electric light and power in this city.

FORT DOUGLAS.—The Utah Light & Railway Company, of Salt Lake City, has secured the contract to furnish current for lighting this post.

VIRGINIA.

MANASSAS.—W. E. Crosen & Co., of Leesburg, are stated to have petitioned the City Council of this city for a franchise to erect and maintain a system of electric lighting for a term of fifteen years. The proposed plant will have a capacity of 750 standard 16-c.p. lamps.

WASHINGTON.

TACOMA.—C. B. Hurley is said to have retired from the Tacoma Gas & Electric Company.

WINONA.—Thomas & McTier are about to establish a light plant to furnish light for this city, Endicott and La Crosse.

SEATTLE.—T. H. Warford, Harry Merritt and B. A. Nelson, all of this city, have incorporated the Sumas Electric Light & Power Company for $30,000 to do a general light and power business.

ELLENSBURG.—Ellensburg is now lighted with electricity from the water-power plant, situated on the river three miles above the town. The new plant has a capacity of 1000 horse-power.

REARDAN.—J. M. McDowell has begun the work of installing the electric plant for which the Reardan council recently granted him a franchise. He expects to have the town lighted very shortly.

GREY'S HARBOR.—Manager J. D. Crary, of the Grey's Harbor Electric Light & Power Company, has recommended purchasing $75,000 worth of new machinery to be used in changing over the electric light plant at Aberdeen, this State.

SEATTLE.—The Council is arranging to place all the companies, corporations and persons doing an electrical business, under the City Electrician, all work to be done in accordance with the National Electric Code.

SEATTLE.—The municipal electric light plant has been placed in operation, and City Comptroller Riplinger is about to ask for bids for $250,000 bonds to be used for the purpose of extending the lighting system to the residence portion of the city.

SEATTLE.—The Diamond Ice Company has extended its lighting circuits as far as its present franchises permit. Plans are under way for enlarging the plant, in anticipation of extending its system as soon as the necessary franchise can be secured.

TACOMA.—Mayor George P. Wright expects ultimately to be in a position to submit to the City Council a proposition whereby the city will own its own electric light plant. Parties are willing to erect and install a plant and take in payment therefor bonds guaranteed by the revenues from the plant.

SPOKANE.—It is rumored that the Spokane Light & Power Company, composed of George Turner, F. P. Hogan, J. C. Williams and others, which has a franchise in Spokane to lay wires for electric lights, heat and power purposes, is preparing to take advantage of its franchise and install a system.

WEST VIRGINIA.

BERKELEY SPRINGS.—The Berkeley Springs Light & Water Company has been incorporated, with a capital of $25,000, for the purpose of establishing water works and an electric light system.

WISCONSIN.

NEW LONDON.—It is expected that the new electric light plant, now in course of construction, will be completed soon.

ONALASKA.—A petition has been filed with the Council by D. L. Aiken and others for a franchise for an electric light plant.

DODGEVILLE.—Frank H. Pavey has recently assumed the management of the Dodgeville Electric Light & Power Company, of this place.

IRON RIVER.—The Iron River Water, Light & Power Company, of which F. F. Macmiller is president and Byron Ripley, secretary, has increased its capital stock from $25,000 to $100,000.

LA CROSSE.—Announcement has been made that the Wisconsin Light & Power Company, which was recently granted a franchise, will erect its plant on the north side, and will probably extend its service to Onalaska.

CANADA.

SHERBROOKE, ONT.—The contract between the city of Sherbrooke and the Sherbrooke Power, Light & Heat Company for lighting the streets having expired, the company has made an offer to the city stating that if a contract for ten years is entered into it will reduce the rate from $60 to $50 per light per year, and give a discount of 10 per cent. on the meter rate.

American Electrician.

Vol. XVII. New York, April, 1905. No. 4.

POWER AND LIGHTING EQUIPMENT OF A CALIFORNIA HOTEL

ENGINEERING FEATURES OF "THE POTTER" AT SANTA BARBARA, CAL.

BY C. W. WHITNEY.

At Santa Barbara, Cal., is located The Potter, one of the largest and most up-to-date hotels in the West. Designed to cater largely to the tourist trade, the hotel has been built to provide every comfort and pleasure possible for its guests, and provision for its own utilities has also been made to an interesting extent. The hotel has an independent water supply, which in that district means much, and from its own power station are provided steam heating, hot water, electric lighting, power, refrigerating, and drinking-water services. The engineering details of these installations, as well as other features of mechanical or electrical interest, which have been provided for the safety and convenience of guests and employees, will be brought out in the following description.

The Potter, stands on an elevated tract of land, 30 acres in extent, facing the Pacific Ocean, from whose beach its grounds are separated by a broad city boulevard. The style in which the hotel is built is Spanish Renaissance, arranged with wings so that there are no inside rooms, the views being toward the ocean for some, toward the Santa Ynez Mountains for others, while some rooms have views of both. The structure is frame, with plastered walls, the roof being finished with Spanish tile. Nearly 500 guest rooms are provided, as well as offices, spacious dining halls, loggia, ballroom, kitchens, storerooms, etc. In two

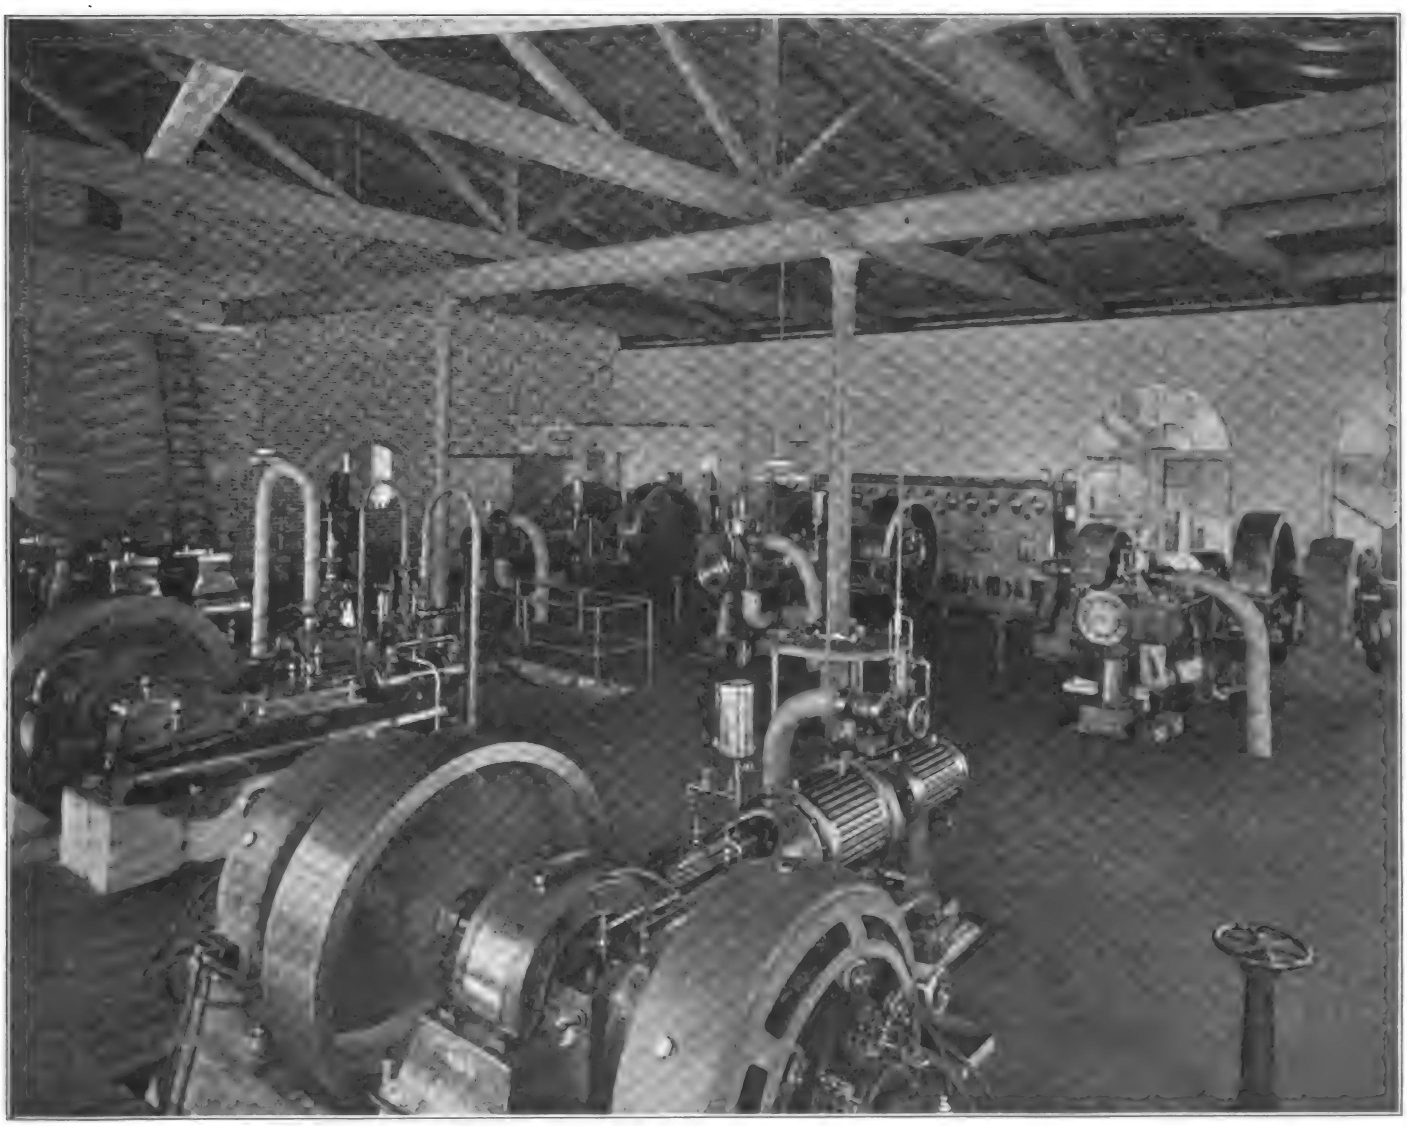

FIG. I.—GENERAL VIEW OF THE ENGINE ROOM OF "THE POTTER."

separate buildings in the rear of the east wing are the laundry and the quarters for the help, while adjoining the former and back of the central wing is the power house. Fig. 2 is a plan view of the boiler and engine rooms, and shows the general arrangement of live steam, exhaust and water piping.

The power house is constructed of brick, the outside being plastered and painted in harmony with the other buildings. The house is divided into a boiler room 56 ft. by 60 ft., and an engine room, 60 ft. square. Adjoining these in the rear is a shop 50 ft. by 30 ft., in one corner of which are located lockers and wash and bathrooms for the station attendants.

In the boiler room there are four Cahall horizontal water-tube boilers, rated at 225 horse-power each. The two 30-in. drums of each boiler are connected to 12 9-tube headers, making a total of 108 4-in. tubes per boiler. Two 11-in. by 15-in. manholes are provided in each drum. The boilers have Reliance water columns with high and low-water alarms, one on each drum. The twelve rear headers are connected to a cast-iron mud-drum, which has three 6-in. by 8-in. handholes, and is provided with two 2½-in. blow-offs, with asbestos stops and Crane angle blow-off valves. These blow-offs are all connected to a 4-in. pipe that leads to a tank 4 ft. in diameter and 12 ft. long. This tank has an 8-in. vent extending through the roof of the boiler room, and a 4-in. drain line to the sewer. There is also a 4-in. by-pass around the blow-off tank that is used in draining dead boilers and in cleaning out.

Each boiler is equipped with two 4-in. pop safety valves, set to blow off at 135 pounds, two 8-in. gate valves with 2-in. by-passes in the main steam line, and one Ashcroft 260-pound steam gauge.

All four boilers are connected to a breeching in the rear, and thence the hot gases are carried to a brick stack, 125 ft. high, built square for 16½ ft., and then round to the top with an inside diameter of 66 in. The top is capped with stone. The stack is lined with firebrick for 50 ft. The walls are 31 in. thick at the base, gradually tapering to 13 in. under the stone cap at the top. They are supported by a massive foundation of concrete, in which iron rails are embedded.

Oil is employed exclusively for fuel for the boilers as well as for the bake ovens, and the kitchen ranges. The oil used runs from 20 to 22 degs. Baume. It is stored in two steel tanks, 30 ft. long and 7 ft. in diameter, located about 200 ft. from the power house. These tanks hold about 205 barrels each. They are placed underground in a pit lined with concrete, for convenience in unloading by gravity from wagons or cars. At present the oil is hauled in wagons, but a spur track is to be installed so that the tank ears ean be taken directly to the storage tanks. Seepage is taken from the concrete pits by means of an ejector which discharges into the sewer system. Each tank is equipped with steam pipes so that the oil can be heated, if necessary, to facilitate its pumping. The fuel oil pumps,

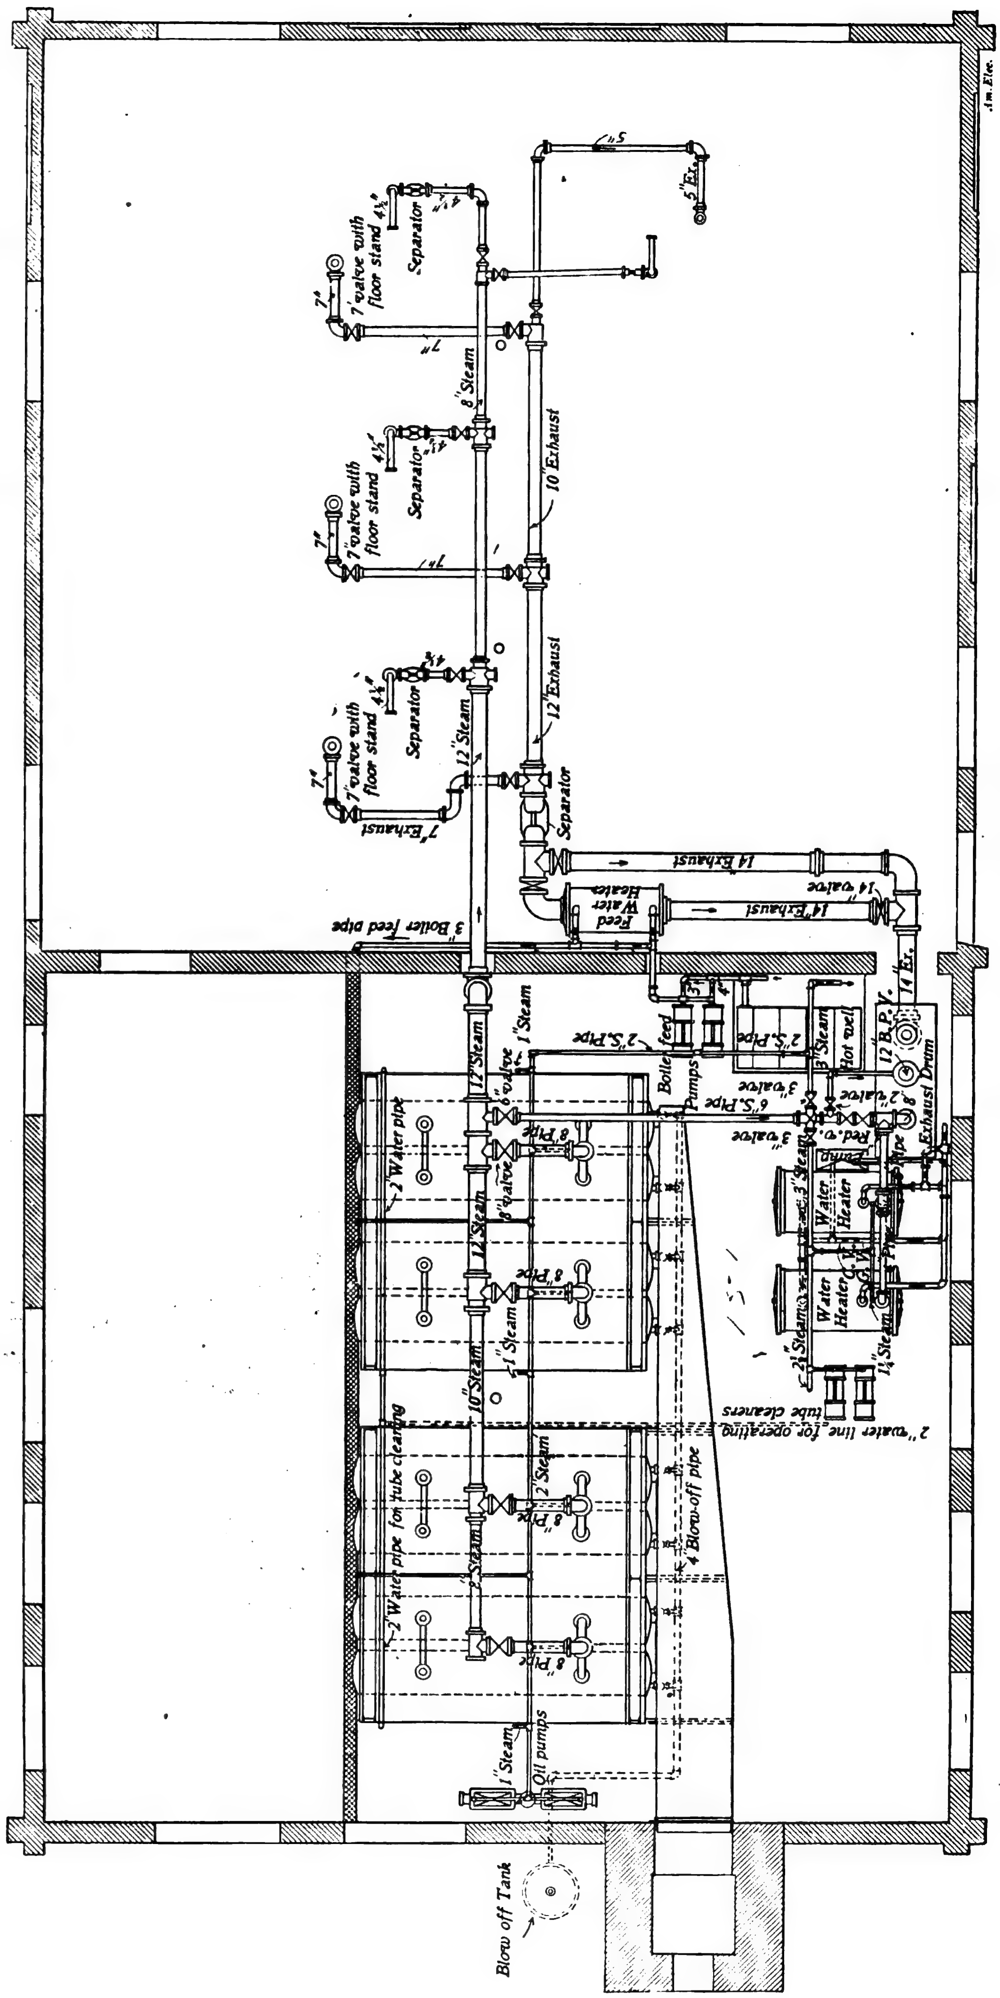

FIG. 2.—PLAN VIEW OF STEAM AND WATER CONNECTIONS.

two in number, are 4½ in. by 2¾ in. by 4 in. in size, of the Worthington duplex type, and are located in front of the boilers. They draw the oil from the tanks and discharge it directly into the burner pipe lines, the surplus being returned to the storage tanks through a relief valve. This system has the advantage of leaving very little oil in the power house at any one time, and that is only what is contained in a small pipe. The oil is atomized by steam in the burners of the bake ovens as well as in those of the boilers. No trouble whatever is experienced with this fuel as long as the burning oil is not thrown directly against the boiler tubes.

The main 12-in. steam line leaves the boilers and drops underneath the engine-room floor, where it branches to the several machines above. Each engine is supplied with an Austin separator, and these are all connected to steam traps that discharge into the hot well. The steam lines were originally suspended from the floor of the engine room, but finding that they caused the floor to sag, the engineer placed all the steam and exhaust lines on stands made of 2-in. pipe. These stands rest on the concrete floor of the basement, and are constructed so as to allow for expansion in the mains.

For boiler-feed purposes, there are installed at the side of the boilers two 7½ in. by 5 in. by 6 in. Worthington outside-packed duplex pumps. These pumps are connected through a 600-h.p. National feed-water heater to the hot well that is located in the rear of the boilers. This hot well is 6 ft. wide and 10 ft. long. It receives the condensation from the steam traps on the engine exhausts, from the hot-water heaters, the steam heating system and the steam auxiliaries.

Fresh feed-water is drawn from two 7000-gallon wooden tanks located over the fuel-oil storage tanks. As the water contains considerable mineral matter it has to be softened before it can be used in the boilers, and the treating is done in these tanks, water being drawn from one while that in the other is settling. F. G. Churchill, the chief engineer of the hotel, experienced considerable trouble from the men letting these tanks run over, so he installed the indicating system illustrated in the diagram, Fig. 5, to give warning at the power house when the tanks are full or empty. Two red lamps are placed in the engine room, each being connected in a three-wire circuit leading to one of the tanks. By means of a float the circuit is closed directly through the lamp when the tank is full, thus giving the lamp full candle-power. When the tank is empty the float closes the circuit through an auxiliary resistance lamp in series with the indicating lamp, thus giving the latter a dim light.

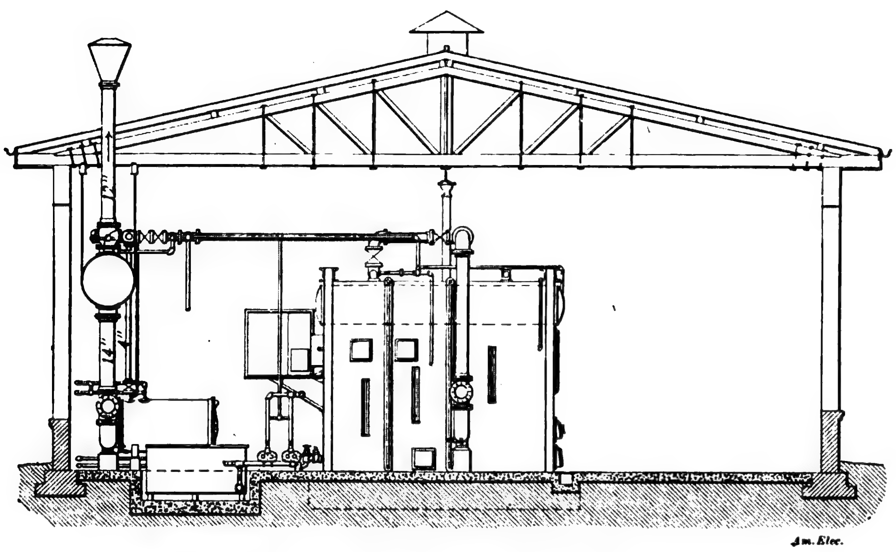

FIG. 3.—ELEVATION OF BOILER ROOM.

Next to the hot well in the boiler room is a 4 in. by 6 in. by 4 in. Moore deep-well pump, which is used to pump all the drainage from the power house to the sewer. An 8 in. by 8 in. by 12 in. Marsh air-compressor is used to lift water from two water wells. In the rear of the boilers are three hot-water heaters used to heat water for the entire hotel. The water is pumped through the hotel by means of a 5¼ in. by 3½ in. by 5 in. Worthington duplex hot-water circulating pump.. For house service there are installed two 6 in. by 4 in. by 6 in. Worthington duplex, and two 6 in. by 7½ in. by 6 in. Blake duplex low-service pumps. These four are used for pumping water for house and irrigation purposes, and also for boiler washing and for pumping water over the ammonia condenser. A 2-in. steam line is taken from each boiler to serve the boiler feed pumps, and, if necessary, it can be used to furnish steam to all of the pumps in the boiler room.

The basement of the engine room is on a level with the boiler room, and besides the heavy concrete foundations of the engines above, it contains the steam and exhaust piping and several auxiliaries. The ammonia condenser for the refrigerator system is installed here, and also a 4½ in. by 2¾ in. by 4 in. Worthington duplex pump, which pumps the water used on the ice machine to the irrigating system. For service in connection with the oiling of the machinery on the floor above, there are in the basement an oil filter and a 2 in. by 1¼ in. by 2¾ in. Blake duplex oil pump. The laundry, kitchen and steam separator traps are also located in this basement, as well as the surge tank, 10 ft. long, 6 ft. wide and 5 ft. deep, which receives the discharge water

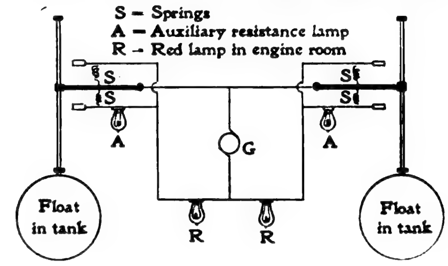

FIG. 5.—INDICATING SYSTEM FOR WATER TANKS.

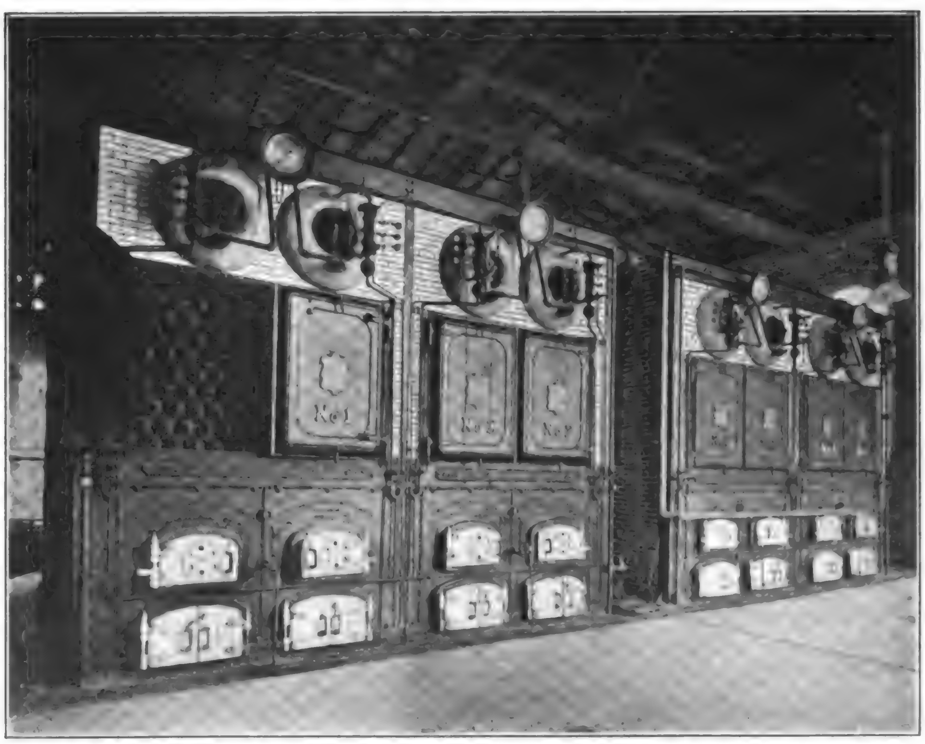

FIG. 4.—BOILER ROOM IN "THE POTTER."

from the hydraulic elevators. The necessary reducing valves on the steam mains leading to the laundry and kitchens, and to the ice machines are also in the basement. Connecting the boiler room and engine room basement with the basement of the hotel building is a large tunnel through which all pipes and wires are carried.

The engine room floor is 8 ft. above that of the boiler room. In this room are located four electric generating sets, one 10 in. by 16 in. Atlas slide-valve engine direct-connected to a 13-ton Barber ammonia compressor and two 12 in. by 18 in. by 10 in. by 12 in. Buffalo compound duplex elevator pumps, as well as the switchboard for the light and power service. On the wall near the elevator pumps are the air pumps used in connection with the elevator system. Two of the generating units consist of 11 in. by 18 in. by 14 in. tandem-compound engines, each direct connected to a 100-kw. 125-volt direct-current generator. The third set comprises a tandem-compound of the same size, direct connected to two 50-kw. 125-volt generators. The fourth engine is a 9 in. by 14 in. by 11 in. tandem-compound, and is direct-connected to two 25-kw. 125-volt machines. The three large engines run at 250 r.p.m., and the small one at 275 revolutions. The engines were furnished by the Ball & Wood Company, New York, and the generators, as well as the switchboard equipment, were furnished by the General Electric Company. Near the ceiling of the engine room is placed a 60-gallon tank for the engine-oiling system. Oil flows from this tank by gravity through pipe lines to the engine bearings from which it drains into a settling tank in the basement. From there the oil passes through a Cross oil-filter into a 60-gallon tank and is then pumped back to the upper tank to be used over again.

Under the kitchen there are provided some 20 cold storage rooms, with 30,000 cubic feet devoted to refrigeration, for fruits, vegetables, meats, fish, poultry, eggs, butter, wines, etc. All of these rooms, except those for poultry and fish, are cooled by the circulation of brine, a 6 in. by 4 in. by 6 in. Deane, of Holyoke, duplex brine pump being used to maintain the circulation. In an ice room is a large brine tank, also served by this pump, for the manufacture of ice for the house use. The fish and poultry storage rooms require lower temperature than is afforded by the brine, so they are cooled by the direct expansion of ammonia, the compressor being located in the engine room as already stated.

To furnish all the water needed for the hotel and its many departments, to irrigate the 30 acres or more of lawn and flower gardens about the hotel during the long dry season, and to afford adequate fire protection, requires a reliable and ample water supply. This is obtained from three sources, viz., the city mains, Mr. Gates' private water works and wells on the hotel grounds. For storage purposes there are provided three large wooden tanks. Two of these have a capacity of 45,000 gallons each, and are built up 24 ft. above ground. They receive water from the Gates private water works, half a mile distant, the pumps being electrically driven by power transmitted from the hotel power house. This water is fed by gravity to the softening tanks for boiler use, and is also pumped throughout the hotel for general purposes. The third tank has a capacity of 30,000 gallons, and is 40 ft. above ground. Its water is pumped from the hotel wells and is used almost exclusively for irrigation. The towers of all three tanks are built of Oregon pine, and rest on concrete piers. The tanks are built of 16-ft. redwood staves, and are covered with conical-shaped shingled roofs.

The water from the city mains is delivered to the hotel at a pressure of 140 pounds. It is used principally for the fire system to which it is at all times connected. The fire system comprises stand pipes, to which are connected 4000 ft. of 2½ in. hose and 3000 ft. of 1½-in. hose. In case of fire almost all parts of the building can be reached without having to stop to connect up any hose. There are also numerous fire-extinguishers distributed about the hotel. . As a further precaution there is a fire department organized among the employees, which is called out by a whistle on the power house roof, a code of signals being used to indicate the part of the house where assistance is needed.

There are several new wells to be drilled on the grounds and a new reservoir of 100,000 or 200,000 gallons capacity is to be added. The elevator pumps are to be connected so that they can pump water directly from the reservoirs to the fire lines, and means will be provided for filling the reservoirs from four different sources, thus assuring plenty of water in case of fire. Especial care is used to furnish pure drinking water, an elaborate filtering and condensing system being installed for that purpose.

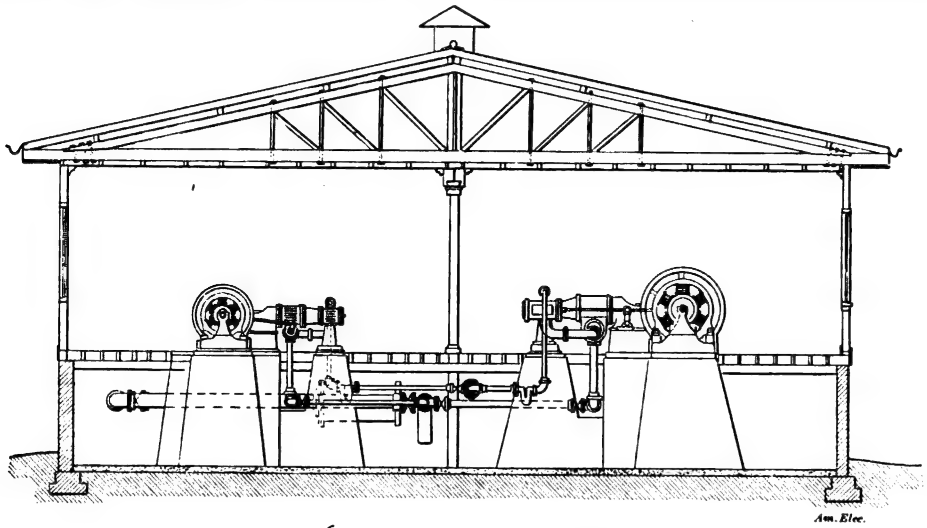

FIG. 6.—ELEVATION OF ENGINE ROOM.

There are seven hydraulic elevators in the hotel. The two passenger and one freight elevators are geared 8 to 1, a waiters' elevator is geared 6 to 1, and a linen elevator has a gear ratio of 10 to 1. All five of these serve six floors. In the kitchen wing are a storeroom lift and a butcher's lift, each serving two floors. For operating the elevators water is delivered from the large pumps in the power house into a large compression tank under 125 pounds pressure. The water then passes to the cylinders of the elevators and thence back to the surge tank, thus making it possible to use the same water over again. Considerable trouble was experienced at first with the water, as corrosion would set in wherever there was any wrought iron or steel exposed to the water. This difficulty has been met by using the drainage from the exhaust separator instead of fresh water in the entire elevator system. This has not only stopped corrosion, but the engineer has also found that there is not required one-fourth the packing that was formerly necessary in the pumps or rams on the entire elevator system.

The light and power service of the hotel is operated on the Edison three-wire system, the lamps taking the single voltage at 110 volts and the motors running on 220 volts. The generators are all compound wound, and so connected that any of them may be run together or they may be cut in on either side of the three-wire system. The switchboard which controls the generators is made of six panels, one for each machine, the equipment of each panel consisting of Thomson astatic ammeter and voltmeter, three-pole, double-throw generator switch, circuit-breaker and Thomson recording wattmeter. There are no feeder panels, the rubber-covered wires being taken directly from ⅜ in. by 3 in. copper bus-bars at the rear of the board, down into the basement and thence to the main building through the pipe tunnel. There are 11 No. 0000 circuits, three of No. 000, two of No. 1, and three of No. 4 wire. In the basement the circuits are distributed to the various pipe wells, which run up through the building, and from these wells are carried to tablet boards of various sizes in the different halls and corridors. These tablet boards are built of white marble and are mounted behind glass doors. Each controls a section of the building and contains a main knife switch, hall light switches, switches for cutting out certain groups of rooms, and the necessary fuses. The wires are carried on porcelain knobs and through circular loom, porcelain tubes being used for holes in joists. All joints are soldered and well taped. The hall lights are all con-

nected to magnetic switches, which are operated by batteries. These switches can be turned on or off at the respective tablet boards, or they can all be handled from a set of push buttons in the main office. The large number of group lights in the general office, loggia and adjoining rooms are handled from a marble panel in the office equipped with 155 knife switches.

In all there are about 12,000 incandescent lamps installed in the hotel and adjoining buildings. Most of these are of 16 candle-power, some 8 and some 4 candle-power lamps being used for decorative purposes.

For exterior illumination along the walks and drives about the grounds some 20 multiple arc lamps are installed. They are of the Adams-Bagnall 110-volt enclosed type. These arcs are controlled from a small switchboard equipped with eight switches and located in the engine room.

The electric motor equipment is installed principally in the hotel laundry and in the kitchen. In the former, which adjoins the power house, there are 20 hands employed, and the most modern machinery is provided. Here all the hotel washing is done, as well as bundle work for the guests. The machinery is run by one 15-h.p. and one 7½-h.p. 220-volt Westinghouse motor.

The kitchen is likewise fitted up with the most modern utensils, the equipment including two large ranges, two broilers, four stock kettles, three steam tables, seven dish warmers, two coffee urns, one hot water urn, and 12 automatic egg-boilers. Two dish washers, a bread crumbler and a knife polisher are run by a 5-h.p. 220-volt Crocker-Wheeler motor. In connection with the kitchen are pastry and bake ovens heated by fuel oil, and six cold storage boxes cooled by brine circulation. Underneath the kitchen and connected with it by the hydraulic lifts already mentioned are the butcher shop and storerooms. Two dumb-waiters are also used to carry supplies from the latter to the kitchen. In the basement are an ice-cream freezer, an ice crusher, a Puritas water pump and a coffee grinder driven by a 5-h.p. Crocker-Wheeler motor. In the vegetable room is a machine for shelling green peas, which does very good and rapid work. It is driven by a 1-h.p. Westinghouse motor. All the flooring in the kitchen and store department is of concrete and is connected to numerous drains, so that water can be used freely in keeping it in a condition of cleanliness.

Electric motors are used in the shop to drive a 22-in. Barnes drill press, a 17-in. lathe and two emery wheels. The shop also is provided with a 2½-in. to 4-in. hand pipe machine and a Buffalo portable forge.

A 220-volt circuit is carried to the Gates water works to furnish current for a 30-h.p. and a 10-h.p. General Electric motor used in driving the pumps. Compressed air is piped to all the generators and to most of the motors for use in blowing dust out of them.

The normal summer load on the electric generating equipment is from 600 to 700 amperes, while during the winter months the load runs up to 1400 or 1600 amperes. The heaviest load that has been carried was one of about 1800 amperes.

A private telephone exchange is installed in the hotel, with about 500 instruments connected. The telephones are of the De Veau type and use 11 volts on the talking and 22 volts on the ringing circuits. In addition to the central exchange telephones, there are six maids' instruments which are switchless, being operated by the user.

In each room in the hotel there is a thermostatic device which operates an annunciator in the office when the room gets beyond a certain temperature, thus affording a safeguard against fire, as well as excessive heat from the heating system.

A system of 40 fire gongs is installed to wake the occupants in case of fire. The gongs are furnished with current at 30 volts from batteries, and are operated from a switch in the office.

The Potter is under the efficient management of Milo M. Potter. F. G. Churchill, chief engineer of The Potter, has had entire charge of the hotel plant for about two years, and has during that time brought the equipment up to a high grade of efficiency, introducing many labor-saving and economical appliances and methods. Acknowledgment is due Mr. Churchill for the data contained in this article and for many of the illustrations.

SOME METHODS OF INCREASING CENTRAL STATION BUSINESS.

BY HOWARD S. KNOWLTON.

Within the past three or four years central station managers have become greatly interested in methods of securing new business, and the results which have followed the efforts of many companies to increase their output have been highly gratifying. In the early days of central station work the rapid development of equipment and well-nigh revolutionary changes in power plant design occurring at that period gave central station managers little time to campaign for new business along the lines practiced so successfully to-day. The capacity of a plant was soon reached, for the mammoth generating units of these times were not in existence, and in some cases there was found a limit to the expansion of equipment through the addition of many small machines. New business steadily increased, but there was not that aggressive enterprise along systematic lines of advertising and demonstration which is now employed in the more progressive organizations.

A study of central station work in different parts of the country, however, shows that many plants operating to-day are by no means doing all the business possible with their equipment. There is room for the exercise of a great deal of practical energy in increasing the output. In the hope of suggesting something useful from the best practice of to-day, the writer has undertaken to discuss the question of increasing central station business, not with the expectation of introducing novel or original methods, but with the idea of emphasizing the innumerable ways in which companies now operating have attempted to reach the public.

To describe in detail the devices which a modern central station is prepared to furnish with current would require nothing short of an encyclopædia. It would take one through practically the entire range of applied electricity, touching upon almost every modern industry, before the ground could be covered. Even if it were possible to prepare a list of all the devices of civilized life depending in some vital principle of their operation upon electricity, the list would scarcely remain complete for a single day. But these resources of the central station are as yet far from appreciated by the general public. It is the opportunity of the central station man, therefore, to bring to the public mind as many of these opportunities as possible, without unreasonable expense. Without saying, the key to the problem lies in the single word—advertise. The sales engineer is needed in the central station no less than in the district office of the manufacturing company.

From an operating standpoint the advantages of increased output are many, especially if the demand can be distributed through a large part of the day, when in most plants a large percentage of the equipment stands idle. As was ably pointed out by Mr. A. W. Zahm in a paper read some months ago before the Iowa Electrical Association, current sold during this period of idleness is a very profitable class of business, and for this reason, especially low rates can often be quoted on certain classes of lighting and other uses of current, without discrimination of an unfair nature against other customers. The point to be kept in mind is the reduction of the ratio of the maximum output to the average. Mr. Zahm divides the field for increasing the output into four different classes—general illumination, power, decorative or advertising lighting, and heating. Among those entitled to specially low rates he includes churches, opera houses and similar public gathering places, since these require a large quantity of current for a comparatively short period at a time when the station peak has dropped off; merchants who have been induced to keep their windows lighted until 11 or 12 p. m. for advertising purposes; electric sign lessees or owners; manufacturers, hospitals, hotels and other customers requiring heat for special purposes during the hours when the lighting load is low; and miscellaneous power users. It is not the object of this article to enter into the question of rates, important as a reduction or modification in them is, in its effect upon the station output. Rate problems must almost always be solved for the particular central station concerned, and although the rates in many plants resemble those in many others, it is important to base them upon the specific conditions locally prevailing, rather than upon what is being accomplished in other localities. Mr. Zahm's paper included a number of general recommendations as to rates which may be looked up by those interested.

One of the most interesting illustrations of central station advertising to be found in practice is the exhibit of the Edison

Electric Illuminating Company, of Boston, on Head Place. Several years ago this company had an attractive exhibit of electrical appliances at the Mechanic's Fair in Boston, and the display proved so popular that it was decided to make the exhibit one of the permanent features of the company's practice. Quarters at Head Place were, therefore, fitted up with improved types of lamps, motors and related machinery, and from this small beginning the exhibit has grown to remarkable proportions. It now occupies two rooms, which are practically filled with apparatus in workable condition, besides an office for the manager of the publicity department, and a storeroom. The attractions of the place have been extensively advertised in the newspapers, street cars and elsewhere, the public being admitted without charge to what is really an up-to-date exposition of central station current consuming devices. Pamphlets describing the equipment are distributed freely. There are comfortable seats for visitors, and attendants are constantly on hand to explain the equipment to interested parties. The company also publishes a small monthly journal called *Edison Light*, which serves to keep its customers in touch with its progress. This is also given away to visitors, and there is a large mailing list of persons to whom the company regularly sends it.

As might be expected, the exhibit is annually visited by many persons, not only from Boston, but from the New England States at large. There are numerous photographs of the company's power plants and sub-stations, representative load curves, etc., mounted upon the walls, and two large books of photographs showing the stages of construction which the larger plants have undergone. In common with other central stations, the Boston Edison Company has no use for the isolated plant, and one of the booklets given away shows photographs, and presents some of the principal details of about a dozen isolated plants in the vicinity of Boston which have been displaced within the past year or two by the Edison service. The booklet further points out the limited capacity of isolated plants in comparison with central station service.

The exhibits are classified under the following six heads: Electrical advertising, domestic appliances, electrical distribution, electric lighting, manufacturing and liberal arts, and electric power and ventilation. During the summer and fall the rooms were kept open from 9 a. m. to 10 p. m., but at present the closing hour is between 5 and 6. The exhibition of electric signs comprises many different forms, from simple sign letters to automatic flashing combinations, and from changeable signs to miniature lamp signs. Under domestic appliances are included a prepayment meter, heating pads, reading lamps, adjustable fans, electric stoves, tea kettle, chafing dish, water heater, flat iron, sterilizer, coffee pot, oven, broilers, foot warmers, soldering irons, stewpans, immersion heaters, curling iron, griddle, plate warmer, and other devices. The distribution exhibit covers meters, cables, wall boxes, switchboards and similar equipment.

The electric lighting exhibit includes various types of arc lamps, theatre dimmers, lamp replacers, adjusters and cleaners, turndown lamps, shades, brackets, adjusters and other fittings.

As one would expect, the greatest variety of equipment is shown under the heads of manufacturing and power. There is almost no limit to the appliances which could be shown under this classification, if space permitted. The entire range of electric motor operation would be but a part of the equipment required to make a complete industrial exhibit. As it is, the Boston Edison Company here has in operative condition an electric forge, which in a few seconds heats a rod of iron up to the welding point, motor driven saws, coffee and spice mills, drills, ice crusher, compressors, ice cream freezers, organ blowers, chopper, carriage call, elevator, sewing machine, pumps, marine sets for lighting and power, glue pot, cigar lighter, lathes, hoist, massage machines, milk shakers, candy puller, laundry machinery, blowers, carpet cleaners, a refrigerating machine, automobile batteries, cold-air regenerator and other apparatus.

There are many practical suggestions to the central station man in the folders and pamphlets given away to the visitors at Head Place. Some of these are published by the makers of equipment, others by the Edison Company itself. The manager, who runs his eye over these publications, is almost certain to find the advantages of different methods of using electricity succinctly stated for the public's benefit, which is exactly what he is likely to be interested in, in his own commercial territory. Thus, the circulars describing electric heating apparatus emphasize the flexibility of the equipment, its convenience, concentration of heat exactly where it is needed, and only while it is needed; the elimination of smoke, soot, poisonous gases, and danger of explosion common to other kinds of heating like alcohol lamps. The cost may or may not be a serious question, after these problems are determined. The quickness with which water may be electrically heated in the nursery and sick room, in hotels when traveling, in the parlor for afternoon tea, etc. are also emphasized. The convenience of electric flat irons, saving of time and wasted heat by their use, and the advantages of many other forms of heaters, are duly described.

One of the pamphlets discusses the problem of motor-driven sewing machines; another describes single-phase alternating 60-cycle motors from 1 to 15 horse-power in self-starting types; and another explains the procedure of the company with regard to inspection from the Boston wire department when new installations are projected. Still another publication of the company records the story of an electric automobile run from Boston to New York and return, with a map of the route and list of charging stations. Automobiles can, in fact, be charged at Head Place. The efforts of the Edison Company to establish charging stations in the entire suburban territory around Boston from Newburyport on the north to South Framingham on the west and Brockton on the south have been largely responsible for the recent increase in the number of electric automobiles used in eastern Massachusetts. Inasmuch as every alternating central station in the country uses direct current in the excitation of its generator fields, there ought not to be the slightest difficulty in charging electric automobiles at such plants, even though a resistance may have to be used for cutting down the current. It means little if central stations here and there offer charging facilities, as the radius of action is limited, with electric automobiles. Every town having a central station ought to have its charging facilities advertised at a few prominent points on the highway by neat signs, directing the chauffeur to the plant and giving the hours during which it is open for business.

One of the best of the Edison Company's publications is a small pamphlet setting forth the advantages of electric arc lights as contrasted with gas lamps. This pamphlet, entitled "Daylight at Night," points out in terse and positive language the vital features of the arc light. It briefly describes the factors which are taken into account when the company's experts make a plan for lighting a place, emphasizing the fact that considering the number of cubic feet adequately lighted the arc lamp is actually superior to candles, kerosene or gas, at less cost of operation. Following this is a brief statement of the theory of light waves, with curves showing the close relation of the arc light to the sunlight and the discrepancy between the latter and gas illumination. The pamphlet closes with a short discussion of the physiological effect of inferior lights and the relative distribution of illumination from gas lamps and enclosed arcs.

Another company which has introduced many modern ideas in the way of gaining new business is the Denver Gas and Electric Company. At the main office on Seventeenth Street, is a comfortable waiting room for the use of the public where nuerous appliances are on exhibition, pamphlets laid out for distribution, etc. A demonstration hall forms part of the building, where lectures can be given for public enlightenment. An interesting exhibit in the waiting room is an electric meter mounted on a small switchboard and connected with various snap switches and lamps of different candle-power, so that anyone who desires can watch its action under different loads. A pithy explanation is printed below the meter, for the benefit of the public. This company keeps in close touch with its customers and frequently sends them folders or other printed matter emphasizing this or that apparatus as suited to their needs. Not long before the writer left Denver the company mailed its customers a neat postal card pointing out the advantages of numbered porch lights for residences, giving the cost of the service per evening, and touching upon the inconvenience which attaches to efforts to

find house numbers on dark streets—an experience with which everyone is personally familiar. The company also published a neat booklet giving a partial list of the uses of gas and electricity in various industries from assaying to wood working.

Small companies, of course, cannot usually afford to adopt the extensive schemes above outlined, in all their details, for securing new business. But it would certainly appear that something can be done, even if it is nothing more than allowing customers and others to visit the station under suitable circumstances, and see the latest "wrinkles" offered for use by the manufacturers. It costs the company little to make such exhibits on its premises, as the manufacturer is usually glad to have this opportunity to display his apparatus. It costs the manufacturer little more than the fixed charges on his equipment as displayed. It is indeed a small and financially straitened central station which cannot afford to spend a little money in the way of advertising its business. Sometimes the daily press can be utilized to good advantage through short advertisements of new equipment or especially desirable apparatus of longer standing. The central station which can afford newspaper advertising might well follow the example of a prominent furniture house in Boston which advertises a single piece with consummate skill every few days, changing the card from time to time instead of inserting a single permanent advertisement.

Finally, it must be borne in mind that central station output cannot be greatly increased by advertising alone. After the prospective customer's attention and interest have been awakened, it remains to complete the transaction by giving him in succinct form the figures and facts which apply to his particular case. This may in some companies be performed by the advertising department, but in others, the services of many different men may be required to close the deal. The engineering department may be called upon to give the results of tests upon similar equipment to that proposed, or the auditing department may be needed to establish the cost of operation of a certain installation. The larger the company the more specialized will be its division of labor, and the results will be felt in securing new business. Central stations have made tremendous progress of late in acquiring motor loads, but the field is still open for progressive development, and will remain so as long as there is a chance for competition in the supply of power and light. Scientific illumination is still to be attained in many quarters, and the future undoubtedly holds radical improvements in store in reference to the production and distribution of artificial light. Time was when the central station and the general public had little in common, but the conditions are changed to-day. Insignificant as the addition of a few lamps or motors may seem in proportion to the total output of a modern urban central station, it is the aggregate of these units which makes up the total connected load, and which helps to make the business profitable.

MODERN ARC LAMPS

BY JOHN HOWATT.

The general supposition that arc lamp development has been practically at a standstill for many years is an erroneous one. It was true of arc lamps some eight or ten year ago, but now each succeeding year shows some development and improvement over the year before. No radical changes are made, of course, nor can there be while the present principles of arc lamp design are retained. Any changes that have occurred have been in the details of manufacture and operation of the lamp.

The recent attention to arc lamp design is due to old lamps having so many faults and giving such poor satisfaction in operation that central station managers and others demanded improvements. All other forms of electrical machinery and appliances had been developed, but the arc lamp was far behind.

The ideal arc lamp for general illuminating purposes must embody the following requisites:

(1) The lamp must be economical. This is of prime importance; for if the cost of operation be prohibitive, all other virtues fail.

(2) The lamp should start rapidly and silently as soon as switched into circuit.

(3) When once thrown into service, it should continue to operate without fail, giving a steady, even light.

(4) The lamp should give a light properly distributed, which can be borne by the eye without discomfort.

(5) The lamp should be shadowless.

(6) The lamp should automatically cut out of circuit when out of order, without affecting any other lamps in the circuit.

(7) The lamp should be compact.

(8) The initial cost, cost of maintenance and cost of repairs should not be excessive.

The first requisite demands something which cannot materially be altered; fortunately the economy of lighting by arc lamps compares favorably with any other method. The second is accomplished by a proper arrangement of solenoids, clutch and dashpot. The third calls for a mechanism for feeding the carbons evenly and a globe for protecting the arc from the wind. The fourth is obtained by a proper use of diffusing globes and reflectors. The fifth can be obtained only approximately; it calls for a lamp with the fewest possible parts below the arc, and these parts, the smallest consistent with strength and rigidity. The sixth requirement calls for a reliable automatic switch; this is of more importance, of course, in series lamps than in constant-potential lamps. The seventh requisite demands that all parts of the lamp be brought together as closely as possible; above all, the lamp should not be long, but this is a fault which has been only partially overcome within the last few years. The eighth calls for several things; the lamp must be made out of some reasonably cheap yet acceptable material which the manufacturer can make duplicate parts of at low cost. For low cost of daily maintenance, the carbon consumption should be low, and the lamp should be so designed that the trimmer can recarbon the lamp in the least possible time. For low cost of repairs, the mechanism of the lamp must be strong and composed of few parts, and the insulation must be good so that the liability of burnouts is reduced to a minimum.

These are the specifications for an ideal arc lamp which have been before the manufacturers since the arc lamp was first introduced, and to design a lamp to meet these requirements has been their aim. But up to about ten years ago the generating end of the system claimed all the attention of the designers and engineers. The arc lamps themselves, where the power was utilized, remained practically the same as when first introduced. And these old lamps certainly left much to be desired, for they did not fulfill any of the requirements of the ideal lamp. They were made up of a complex mechanism of wheels, levers and sliding contacts always getting out of order; they fed very irregularly, and they were by no means compact, some of them being over 60 inches long. When the arc lamps manufactured by the leading electrical companies to-day are compared with those of ten years ago, it will be seen how great arc-lamp development has been.

Among the changes and improvements which have been made in arc lamps within the last ten years, the following may be mentioned: First and most important is the introduction and adoption of the enclosed arc. The enclosed arc has done more than anything else to favor the adoption of arc lamps for general illuminating purposes. It allows a higher potential across the arc, thus making the lamp more economical to use on a 110-volt lighting circuit. The carbon consumption being slow, the feeding mechanism can be simplified, thereby reducing the liability of the lamp getting out of order. In fact, any arc lamp discussion at the present time need only consider the enclosed type of lamp.

Another improvement has been in the length of the lamp, which has been shortened materially; whereas the old lamps were 60 inches long, modern arc lamps are often less than 36 inches long. This has been accomplished by disposing of the lamp rod and having the feed clutch work directly on the carbon rod. This, of course, calls for a good even grade of carbon rod, but the many advantages gained more than compensate for the small added cost of carbons.

In the third place, the lamp design has been made much more simple. It is a strange fact that new designs and inventions are nearly always complicated. Simplicity of construction is obtained only after a process of elimination covering a period of many years. The demand for apparatus which is composed of the fewest parts con-

sistent with proper operation has never been as great as it is at present. This is because simplicity is considered by many to stand for reliability. Arc lamps having long since passed the experimental stage, have now

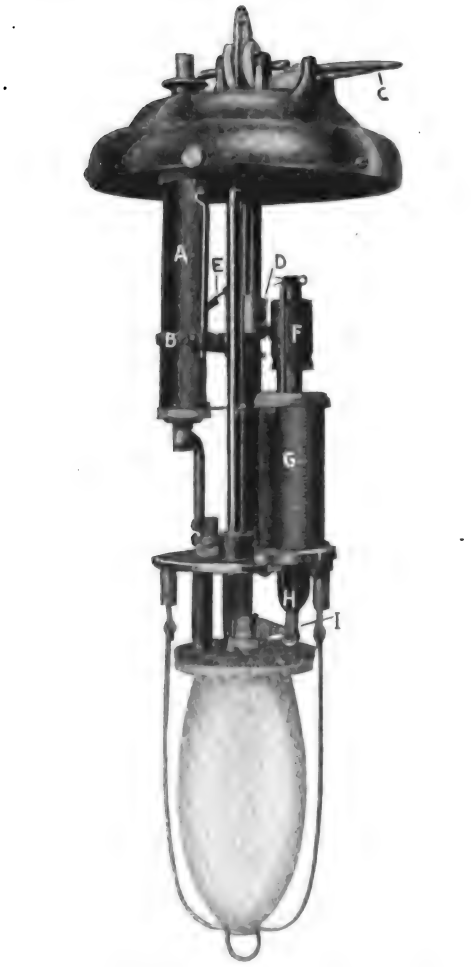

FIG. 1.—GENERAL ELECTRIC DIRECT-CURRENT CONSTANT-POTENTIAL ARC LAMP.

undergone the elimination process, resulting in a lamp with as few parts as it is possible for it to have and operate properly.

Another one of the problems which has been solved within this time is the proper design of an arc lamp for alternating cur-

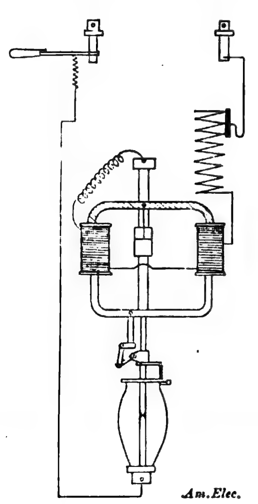

FIG. 1-A.—DIAGRAM OF CONNECTIONS OF GENERAL ELECTRIC ARC LAMP.

rents. The great flexibility of the alternating-current system has caused its general adoption all over the country. To meet this condition it became necessary to design a lamp suitable for operating on alternating-current circuits. The constant-potential alternating-current lamp had been brought out long before this, but it was not a success. It had a low power-factor and made altogether too much noise when operating to come into public favor. Indeed, any alternating-current arc lamp must be very carefully designed to avoid rattling and humming, due to the reversals of magnetism in the reactance coil and the solenoids. That this humming of arc lamps has been successfully overcome is shown by the fact that so many of these lamps are now used for lighting large interiors, such as depart-

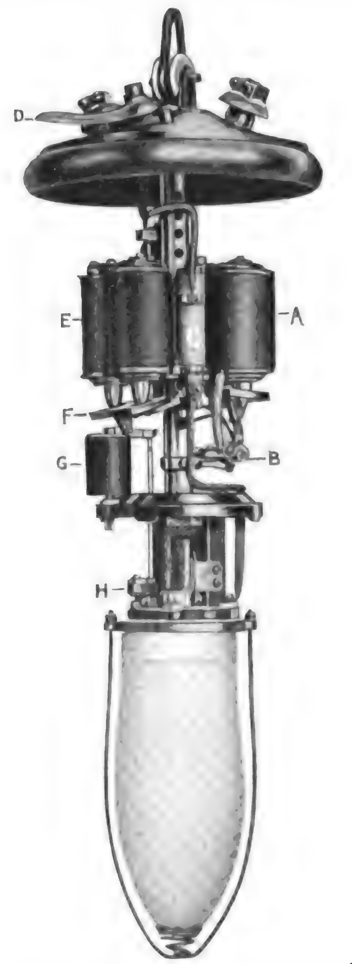

FIG. 2.—JANDUS DIRECT-CURRENT SERIES ARC LAMP.

ment stores and halls, where a noisy lamp would not be allowed to remain.

The series alternating-current arc lamp was not brought out until the advent of the series or constant-current transformer. With a constant-current transformer, such as is manufactured by several of the leading electrical companies, the series alternating-current lamp seems to be one of the best means for street lighting in view at the present time. The transformer regulates closely—more closely than the old direct-current series dynamo—and it is, of course, much more efficient.

There are in use at the present time five distinct types of arc lamps. They are:

1. Series direct-current.
2. Series alternating-current.
3. Multiple direct-current, 110 volts.
4. Multiple direct-current, 220 volts.
5. Multiple alternating-current, 110 volts.

Of these, the series direct-current is the oldest and is now perhaps the least used; for street lighting the series alternating-current lamp will doubtless entirely supplant it. In the constant-potential lamps, 110-volt lamps are more common than 220-volt lamps, although the latter have a great many advocates, especially in the Middle West. The constant-potential alternating-current lamp, used on a high-voltage system in connection with a small transformer, is a rather expensive and cumbersome arrangement and cannot survive.

The accompanying engravings illustrate the different types of arc lamps as they are manufactured and supplied to the trade today. An inspection of them will show how near they come to what an arc lamp should be.

Fig. 1 illustrates a style of direct-current constant-potential lamp for 110-volt circuits, made by the General Electric Company. The lamp embodies several distinctive features in its design, chief among which being the method of winding the magnet coils and the resistance spool. The series magnet coils *G* are wound of bare flat wire on edge and insulated by a non-combustible insulating material. The resistance coil *A* is wound of high-resistance wire in a similar manner. The great advantage of this form of coil construction is

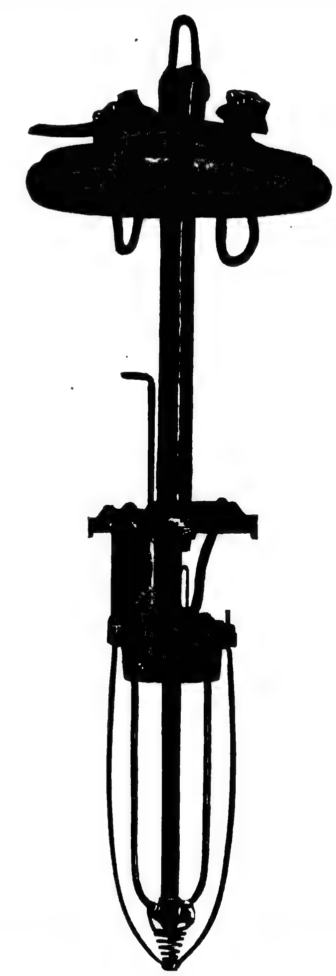

FIG. 2-A.—COMMON FRAMEWORK OF JANDUS ARC LAMPS.

evident to any who have had arc lamps under their care. The ordinary cotton-insulated coils burn out quite frequently, throwing the lamp out of commission. The insulation of these coils cannot burn out.

The main frame of this lamp consists of two steel rods firmly fixed to the upper and lower castings. As the frame of the lamp carries no current, the necessity of insulating these rods from the base is avoided. A dash-pot F steadies the motion of the feeding mechanism. The magnet armature and carbon clutch are shown at H and I. As may be seen, the lamp is of the carbon-feed type, the current being led from the magnet coils to the carbon rod by a flexible connection E. Current adjustment is effected by placing lead washers on the upper carbon holder, as shown at D. Voltage regulation is obtained by varying the resistance of A by means of the sliding clamp, B. C is a hand switch for cutting out the lamp for trimming. Altogether, this lamp embodies many good features.

Fig. 2 shows the lamp manufactured by the Jandus Electric Company for series direct-current circuits. The most noticeable feature of the design of these lamps is the adaptability of one lamp to any service. All the arc lamps made by this company have one common framework shown in Fig. 2-A. A lamp for any desired voltage, for either alternating or direct current, is then obtained by slipping into place on this frame the proper coils and magnets. For central

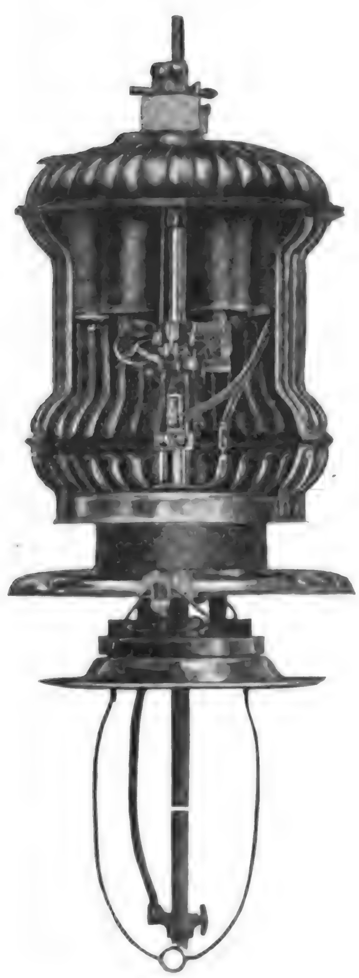

FIG. 3.—WESTINGHOUSE SERIES ALTERNATING-CURRENT ARC LAMP.

stations having a mixed service, both direct and alternating current at 110 or 220 volts, this lamp is especially valuable. The cost of keeping the lamps in repair is materially reduced, owing to the lamps being all of one general style and made of interchangeable parts. This lamp has four magnet coils with pointed poles, two series magnets shown at E and two shunt magnets shown at A. The frame is of the central-tube type

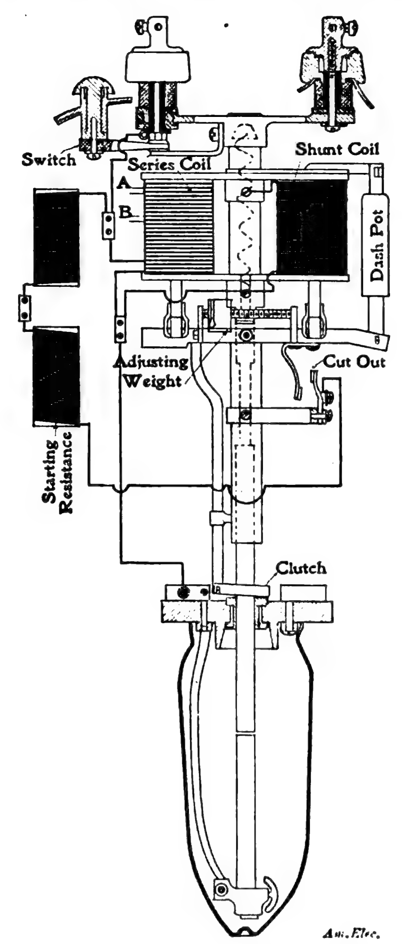

FIG. 3-A.—DIAGRAM OF CONNECTIONS OF WESTINGHOUSE LAMP.

and is of simple and rigid construction. At B is the automatic cut-out with silver contact surfaces. Silver is used in the cut-out because silver oxide, formed by the action of air or the spark on opening the circuit, is still a good conductor, while an oxide of iron, brass or copper has insulating properties. D is the hand switch; F, the perforated armature which operates the carbon rod clutch, H; G is the steadying dash-pot, and C, the resistance in series with the magnets E. It will be seen at once that this lamp is composed of more parts than the multiple type; this is true of all series lamps. In spite of its rather complicated design, this lamp gives good service and is very popular with central station men.

Fig. 3 shows the series alternating-current arc lamp manufactured by the Westinghouse Electric & Manufacturing Company. Fig. 3-A is a diagram of connections for this same lamp. It is seen at once that in a general way the series alternating-current lamp very closely resembles the series direct-current lamp. This lamp operates with 72 volts at the arc and takes normally 6.6 amperes. The series and shunt magnets operate differentially on one rocker-arm which regulates the feed. These magnets are wound on spools moulded from a single piece of vulcabeston. This material has been selected because it has been found to be superior to others for alternating-current work, its use avoiding eddy-current losses and preventing the chattering of the core. The starting resistance is wound on two porcelain tubes placed on opposite sides of the lamp so as not to localize heating effects. In the diagrammatic sketch they are both shown on the same side. The lamp is provided with the two cut-outs usual in all series lamps, one hand cut-out and one automatic. The latter has but one rubbing contact, made of a piece of coin silver fastened with a silver rivet. So close is the adjustment of the lamp that if the potential across the arc increase but five volts above the normal the lamp will be automatically cut out. Current regulation is obtained by shifting the adjusting weight toward the series or shunt coil, according to whether more or less current is desired. The case is made of pressed copper, corrugated for greater rigidity. All the working parts are kept well away from the heat of the arc and arranged so that they can be easily removed and inspected. The insulation of these lamps must necessarily be good. Vulcabeston is used wherever possible instead of porcelain and mica. Each lamp is given a 7000-volt ground test before leaving

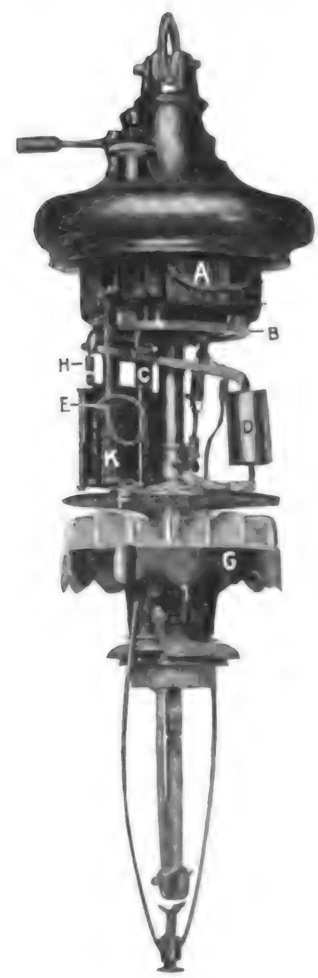

FIG. 4.—FT. WAYNE CONSTANT-POTENTIAL ALTERNATING-CURRENT ARC LAMP.

the factory, so that any insulation imperfections will show up there.

Fig. 4 shows the constant-potential alternating-current arc lamp manufactured by the Fort Wayne Electric Works. These

lamps are designed with especial regard to avoiding vibrations set up by alternating currents. The frame of the lamp consists of a brass central tube inside of which the

FIG. 4-A.—FT. WAYNE REACTANCE COIL.

carbon rod slips. This tube is firmly fixed to a brass casting at the top and bottom. In this style of lamp there is no resistance in series with the arc as the reactance coil, *A*, takes the place of all resistance. Fig. 4-A shows the reactance coil removed from the

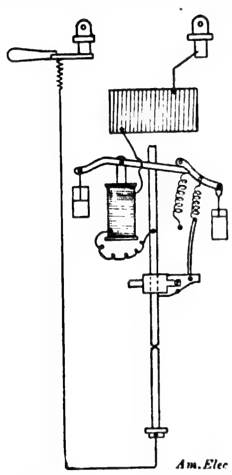

FIG. 4-B.—DIAGRAM OF CONNECTIONS OF FT. WAYNE LAMP.

lamp with core and coil assembled. The reluctance of the magnetic circuit is increased by introducing a fibre strip in the core.

In order to allow for the adjustment of the lamp for various voltages, eight taps are brought out as shown at *T*. This gives a means of adjusting the lamp so that it will operate on any voltage from 100 to 120. The reactance coil is firmly held in place in the lamp by the brass plate *B*. The series solenoids are of double cotton-

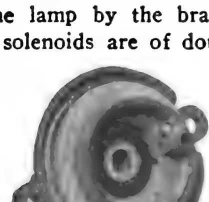

FIG. 4-C.—FT. WAYNE GAS CAP.

covered wire wound on turned fibre spools and are suspended from the bottom of the reactance coil by an oil-tempered spiral spring. The inside of the spool has a German silver bushing to reduce the friction of the armature. The armature, shown at *C*, is of the inverted "U" type, built up of laminated steel punchings held together with German silver rivets. German silver is used because of its high resistance, cutting down the eddy-current losses. The pull of the solenoids on this armature is opposed by an oil-tempered spiral spring. By varying the tension of this spring, the current adjustment is obtained. *D* shows one of the dash-pots, there being one on each end of the armature lever. *H* shows one of the springs introduced to break up any vibration that might arise in the lamp. As a further precaution against vibration, besides all suspensions being by springs, the reactance coil has a felt packing between it and the brass castings, as also have the dash-pot cotter pins. These precautions, while they complicate the design very much, are essential in this type of arc lamp.

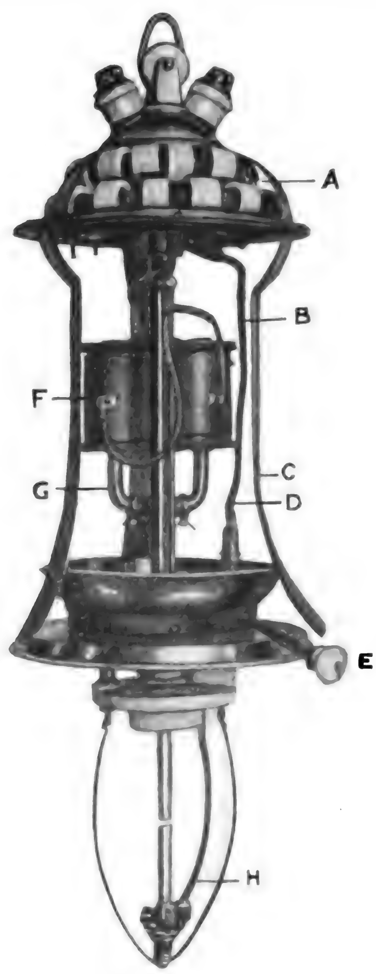

FIG. 5.—ADAMS-BAGNALL DIRECT-CURRENT MULTIPLE ARC LAMP.

G shows a radiator which is intended to keep the mechanism chamber cool. It is made of cast iron, copper-plated, with projecting vanes to present a large radiating surface.

The 220-volt direct-current multiple arc lamp manufactured by the Adams-Bagnall Company, is illustrated in Fig. 5. A comparison of this lamp with the company's 110-volt direct-current lamp shows them to be very similar. The main differences are found in the resistance in series with the arc and the adjustment of the feed mechanism for the different lengths of arc. The simplicity and compactness of this lamp are evident from the illustration. It is of the double solenoid carbon-feed type and is of very rigid construction. In the illustration the resistance is shown at *A*. It is wound in a spiral form, insulated from the lamp frame by porcelain rings. Its location above all the working parts of the lamp insures

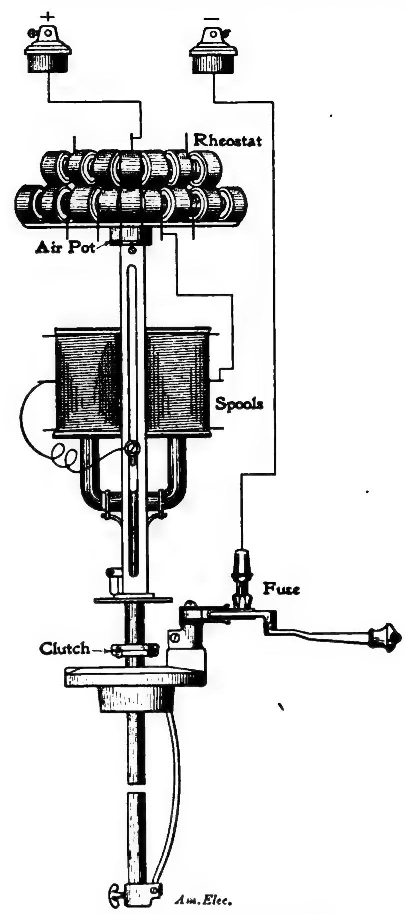

FIG. 5-A.—DIAGRAM OF CONNECTIONS OF THE ADAMS-BAGNALL LAMP.

coolness of the mechanism chamber. Flexible conductors, one of which is shown at *B*, are used throughout the lamp. *C* shows one of the straps used for holding the case in position. The case itself is made of stamped copper, corrugated to increase the rigidity. A door in the case enables the working parts of the lamp to be exposed readily. The series magnets are shown at *F* and the "U" armature at *G*. The extreme simplicity of the armature and clutch is well shown in the illustration. There is but one rod, *H*, for the negative carbon holder. This avoids one of the strong shadows ordinarily cast by arc lamps. The lamp can be adapted to any voltage from 220 to 250 by varying the resistance, *A*. On a 220-volt circuit the lamp takes 150 volts at the arc and a current of 2.5 to 3 amperes. Thus there is no greater loss in the resistance coil than with 110-volt lamps. On account of the higher voltage, the lamp must be designed throughout with greater care as to its insulation. A thorough insulation test in the factory shows any possible weakness in this respect.

The lamps described include all the modern general types and may be considered each as typical of its class. There are a great many other makes of lamps, of course, but these are sufficient to show what the arc lamp developments of the past ten years have produced up to the present time.

THE ARRANGEMENT OF STEAM PIPES.

BY R. T. STROHM.

One of the most noticeable effects of heat is expansion, this being a law which has few exceptions. An ordinary steam pipe, when erected, has about the same temperature as the surrounding atmosphere. Upon admitting steam, however, heat is absorbed by the metal of the pipe and its attachments, which results in increasing their temperature; and this rise in temperature produces expansion of the pipe in all directions.

The rate of expansion is usually expressed as a certain number of parts of the original length, and is called the coefficient of expansion. For cast-iron, wrought iron and steel the coefficients of expansion are as follows:

Cast-iron	.00000617
Wrought-iron	.00000686
Steel	.00000599

Thus, a piece of wrought iron pipe 10 feet long expands $10 \times .0000686 = .0000686$ foot for every degree Fahrenheit increase in temperature. Or, if a steel pipe 300 feet long is heated from 62° to 362° Fahrenheit, the increase in length is $.00000599 \times 300 \times (362 - 62) = .54$ foot or about 6½ inches.

It will be evident, from the foregoing, that when long, straight lines of steam piping are put up, it is absolutely necessary to make some provision for the expansion which will occur as soon as the pipe is subjected to steam pressure. Failure to make proper allowance is certain to be followed by serious consequences. The pipe or some of its fittings may be broken, or the supporting walls split or pushed out by the great force exerted by the expanding pipe.

It is useless to attempt to anchor the pipe rigidly, to prevent this movement. The forces set up by the heat are too great to be thus resisted. To illustrate the magnitude of these forces, a case may be cited in which a steel chimney was badly damaged by expansion. The chimney led up through an office building of some twenty stories. When the stack was put into use it expanded both laterally and longitudinally. The lateral expansion, near the top, caused it to engage with some beams which formed a part of the structural work of the building. The opposite ends of the chimney thus became practically immovable. Consequently, as the longitudinal expansion took place, the rivets in the girth seam of one of the sections were sheared off and the stack simply telescoped.

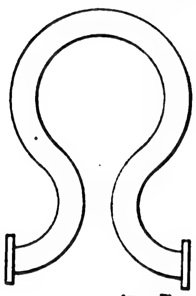

FIG. 1.

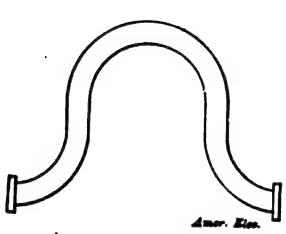

FIG. 2.

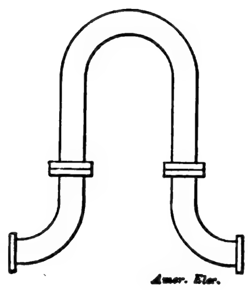

FIG. 3.

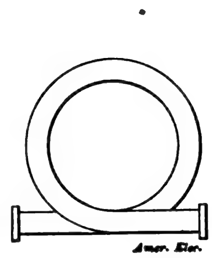

FIG. 4.

There were 48 rivets in the seam, each rivet being ¾ of an inch in diameter. The shearing area of one rivet being .442 square inch, and the shearing strength being taken at 50,000 pounds per square inch, it is plain that a force of more than 1,000,000 pounds must have been exerted, due to the expansion by heat. Of course, steam pipe temperatures are not to be compared with chimney temperatures, but the instance given will serve to show what enormous forces are generated in an expanding pipe.

There are many ways of allowing for steam pipe expansion, but they may be divided into two general classes. First, by arrangement of the pipe in such a manner as to have the movement taken up by the natural elasticity of the material; and, second, by the use of expansion joints.

One method of providing for expansion and contraction is to use a section of pipe bent into the shape shown in Fig. 1, usually termed a gooseneck. It is installed on a straight pipe line. The elasticity of the portion forming the bends is sufficient to take up a considerable amount of longitudinal movement on the part of the straight sections, without seriously straining the bends. The form of bend shown in Fig. 2 is similar to the foregoing, but does not permit the same amount of movement. That illustrated in Fig. 3, formed of two elbows and an inverted U, is open to the objection that the stresses set up, when its lower ends are pushed together, tend to strain the flange joints and are liable to produce leakage on that account.

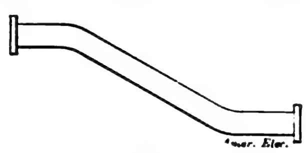

FIG. 5.

In case it is not absolutely necessary to have the whole main in one straight line, the expansion may be taken up by the form of bend shown in Fig. 4, which is a single complete turn of the pipe. In this case the sections connected by the bend will lie parallel to each other but at a distance from each other somewhat greater than the outside diameter of the pipe. In places where the sections may be separated by still greater distances, the bend shown in Fig. 5 may be used. It is not nearly as flexible as the previous forms, but may be used to advantage where the amount of expansion is comparatively small; or, if so desired, a number of these bends may be installed, to take up considerable expansion.

In using the bends shown, care must be taken in order to prevent traps being formed where water may collect, due to condensation in the pipe. If the bend is placed so that its axis lies in a horizontal plane, or if it lies so that its axis follows the slope of the pipe line, then there will be no pockets formed. But it is not always possible to place the bend in such positions. Owing to limited space, it may be necessary to place it in a vertical plane, with the loop either above or below the center line of the main pipe. When this is done, it is necessary to use automatic traps by which the pockets in the bends may be kept free from water.

Unless this precaution is taken, water hammer will result, with its dangers to the plant equipment and to the attendants. It is evident that if a plug of water is caught up and carried along with a steam current traveling at the rate of a mile a minute, serious damage is liable to result when the incompressible volume of water strikes an elbow or a valve in the pipe. For the same reason the pipe should have a gradual slope downward in the direction of flow of the steam current, so that there may be no counter-current of water of condensation to oppose the flow of steam. Exception to this rule may be taken when the pipe is quite large for the work it has to do, in which case the velocity of the steam current will be low.

A form of expansion joint which is used to some extent is shown in Fig. 6. It consists of a section of corrugated pipe, usually made of copper, inserted in the pipe line. Its action, under the effects of contraction and expansion, is similar to that of the old-time accordion. Owing to the large number of corrugations included in a short length of pipe, this form is capable of taking up considerable expansion.

In many instances, these bends have been put into the pipe line in such a way as to be in tension when the line is cold. That is, they are stretched somewhat, to make their flanges meet those of the pipe sections. As the steam is turned on, and expansion of the line occurs, the tension gradually grows less, until a point is reached at which the bend is under no stress at all, as far as expansion is concerned. As the expansion continues, the stresses are reversed, and the bend is compressed. Thus, it is possible to arrange the bends so that the stresses will be divided equally on opposite sides of the normal state.

The types thus far noted take up all

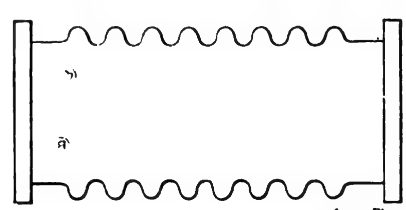

FIG. 6.

movement by their natural elasticity. A second class of expansion joints, however, lack this property entirely, and employ a slip joint, by means of which one section of the pipe slides into another after the manner of a telescope. Such a joint is il-

lustrated in Fig. 7. It consists of a cast-iron section, *A*, enlarged at the end so as to form a stuffing box, *B*, through which extends the pipe, *C*, which forms a portion of the main steam line. A gland, *D*, forced downwards by the nuts, *E*, *E*, on the stud bolts, *F*, *F*, compresses the packing, *G*, in the stuffing box, *B*, thus preventing leakage of steam between the pipes, *A* and *C*, yet at the same time allowing the pipe, *C*, to slip into or out of the section, *A*, as the changes in temperature alter the length of the main.

There is a pressure on this joint in a

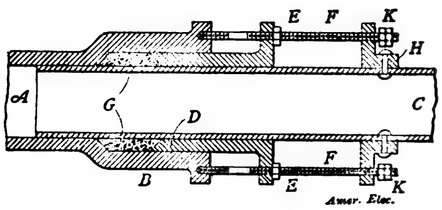

FIG. 7.

longitudinal direction, equal to the internal area of the section *A* times the steam pressure in pounds per square inch. This force tends to separate the sections *A* and *C*. The effect of parting these pipes, under full steam pressure, would be disastrous. To guard against any such possibility, the studs, *F*, *F*, are made very long, so as to extend back through the flange, *H*, riveted firmly to the pipe, *C*, and are fitted with nuts, *K*, *K*, which just miss touching the flange, *H*, when the pipe is cold. The pipe, *C*, is thus free to move longitudinally to accommodate the change of length of the main, yet it cannot slip wholly out of the section, *A*, because of the restraining nuts, *K*, *K*. It is possible to balance this form of joint simply by the steam pressure in the pipe, but the construction is considerably more complicated and the cost made correspondingly greater.

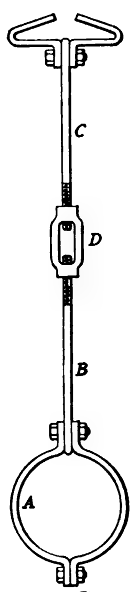

FIG. 8.

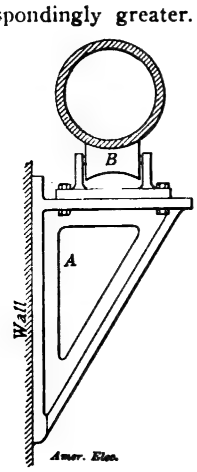

FIG. 9.

It is noticeable that the type of expansion joint shown in Fig. 7 is being employed to a far less extent than formerly, the long bend being the ordinary means of taking account of expansion. The reason for this lies in the fact that the packing in the slip joint is apt to grow hard, and eventually leak. Also, there are cases in which the slip joint failed to slip as it ought, with the result that walls were demolished. The cost of a good expansion joint of this class is another disadvantage, when compared to that of a bend of pipe. It should be used only in places where the other forms are out of the question.

There are various methods of hanging or supporting pipe lines so as to enable the expansive movement to take place without damage to the pipe. In case the main is suspended from girders of roof trusses, the form of hanger shown in Fig. 8 is frequently used. It consists of a ring, *A*, of flat iron, made in two parts, which after being put around the pipe are bolted together. The upper bolt passes through the eye of an eye-bolt, *B*, which is connected to a second eye-bolt, *C*, by the turnbuckle, *D*. These eye-bolts are made of round iron with welded eyes and have right and left-hand threads, respectively. The upper one is joined to two straps which hook over the flanges of an I-beam and are held in place by a bolt and nut. When a pipe is suspended by a number of these hangers, the movement due to expansion or contraction simply swings the rods, *B* and *C*, about the upper point of support.

If the pipe line is supported on brackets, as, for example, when it is carried along a wall, then some arrangement like that shown in Fig. 9 may be used. The bracket *A*, is secured rigidly to the wall. It carries a cast-iron roller, *B*, whose curvature is the same as that of the pipe. The pipe being anchored at the middle of its length, expansion in either direction simply turns the roller, *B*, as the movement occurs, thus preventing any binding of the pipe. Means of adjusting the roller in any direction should be provided. This may be done by wedges and by oblong bolt holes in the plate carrying the roller.

THE POWER PLANT OF A MODERN TELEPHONE EXCHANGE.

BY A. DALLAM O'BRIEN.

The introduction of the common-battery telephone system brought with it the necessity for a source of power at the central office, and as each additional refinement of the system has been perfected, greater and more varied demands have been made on this central source of power, until at the present time every modern central office has incorporated in it a power plant which is in its way a most complete installation.

It is of the utmost importance that the current which is furnished both to the operators' transmitters and to the subscribers' lines for talking purposes should be furnished at a constant potential or a potential whose variations at each succeeding instant shall not be of sufficient magnitude to affect the sensitive transmitter; and for this purpose there is no source of power which so pre-eminently fulfills the requirements as does the storage battery. As a consequence the basis of all central office power plants is the storage battery, and the differences which may be observed between various plants will be largely in the method employed for charging the batteries.

A potential varying from 20 to 24 volts may be considered as the standard in use

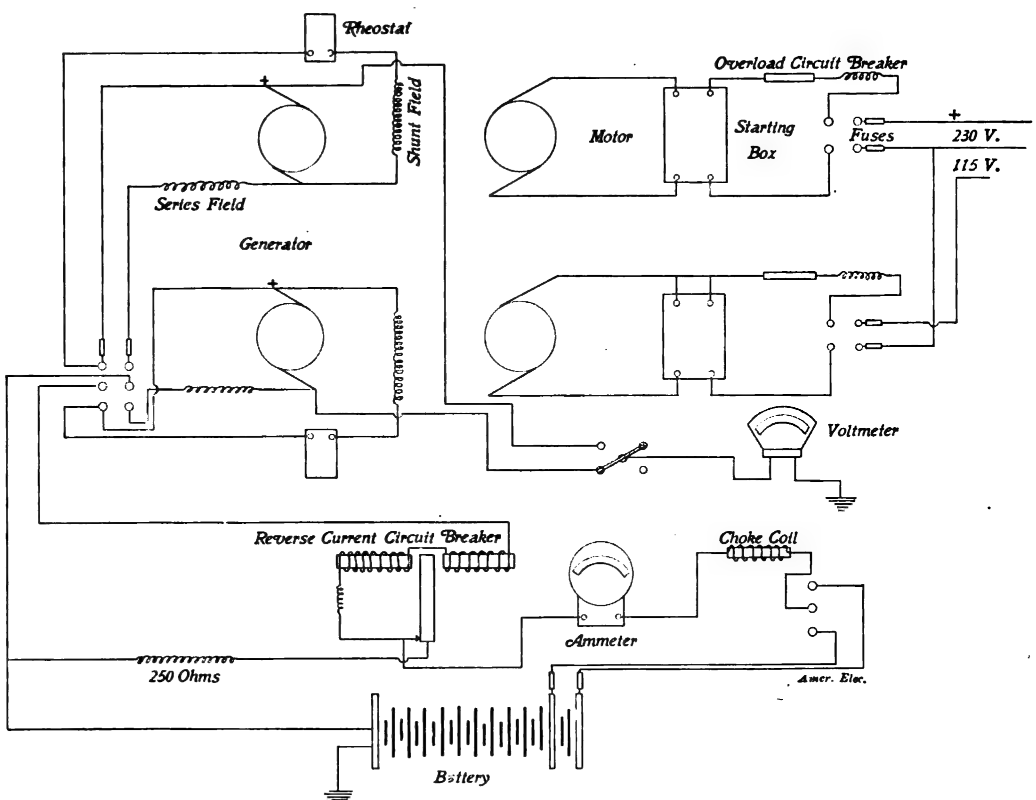

FIG. I.—DIAGRAM OF CONNECTIONS FOR CHARGING CIRCUIT.

to-day, both for the current furnished to the line for talking purposes and also for operating the signalling apparatus at the exchange. If the voltage of each cell is taken as 2.5, when the cell is fully charged, it will be seen that in order to obtain a 24-volt battery it is necessary to employ ten such cells connected in series, and further, if the discharge from the battery is con-

tinued until the voltage per cell drops to 1.8, two additional regulating cells will be required in order to maintain constant constant at all times a potential of 24 volts.

From the above considerations, it will be apparent that in order to maintain at all times a constant potential of 24 volts, and at the same time discharge the batteries until the voltage per cell drops to 1.8, there will be required a battery consisting of twelve cells. two of which are used solely for regulating purposes and may be arranged so as to be automatically cut in or out of the circuit as the condition of the battery requires. In designing the battery equipment for a given office, the size of the cells to be used will, of course, depend upon the output required of the battery, and this in turn is a direct function of the number of originating calls and also depends upon the distribution of these calls throughout the period of twenty-four hours during which the battery is called upon to furnish current. It is probably safe to consider that during each connection which is completed at the exchange a current amounting to 2/5 of an ampere is drawn from the battery, and if three minutes (which is considerably greater than the average) be taken as the average length of connection, the output of the battery for each completed call amounts to 1/20 × 2/5 or 1/50 ampere-hours. From these data, and knowing the number of originating calls and the maximum number of calls during any one hour, the capacity or size of the battery necessary to supply the needs of the office may be very closely approximated.

The size of cell having been determined, the next question that arises is the method to be employed in charging the battery, and as it is of the utmost importance that every possible precaution should be taken to insure the absolute readiness of the battery for service at all times, at least two possible means of charging should be provided so that in case of the failure of one arrangement the other may be called into play. Where an outside source of current is available, it may readily constitute one of the means of charging, the other means being located in the office itself.

For the inside source of power the gas or oil engine is ordinarily adopted as it requires no boiler plant and comparatively little attention. In very small offices, which constitute one of a group in which there are one or more large exchanges, the batteries may, in case of necessity, be charged from one of the other offices, and thus it is possible to dispense with more than one source of power. In large offices, however, where the originating calls amount to 15,000 a day or more, every precaution to insure the continuity of service should be taken; two motor-generator sets, consisting of a motor and generator direct-connected on the same shaft, should be provided. In addition to these there should be an engine-driven unit, consisting of a generator either belted or direct-connected to a gas, oil or steam engine, according to the conditions which govern the installation. The motors which drive the charging machines should be so arranged that they may be driven either by means of current furnished from some outside source or else by the current furnished from the generator located in the exchange building. It may often happen that the voltage of the outside source differs from that furnished by the generator in the exchange, and in this case the motor-generator sets may be so arranged that one will operate on the outside current and the other upon the current furnished by the exchange generator. A typical arrangement of a charging circuit of this kind is shown in Fig. 1, this circuit being an example of an actual installation in an exchange handling 20,000 originating calls per day.

From an inspection of this diagram, it will be seen that in this case the outside source of current has a potential of 230 volts, while the office generator delivers current at 115 volts. The generators are compound-wound machines and are connected to the charging circuit by means of a double-pole, double-throw switch, which allows of throwing either generator on the circuit at will. The positive side of the charging line to the battery is connected through a polarized relay which operates at once to break the circuit in case the potential of the battery rises above that of the charging generator, and the battery in consequence tends to run the charging machine as a motor. In addition to this a choke coil is connected in series with the positive side of the charging line and serves to prevent sudden variations in the potential of the charging current from affecting the battery.

There are a number of other small generator units which go to make up the power equipment and these are usually so designed that they may be driven by the 24-volt current from the battery. These small machines are used for a number of different purposes; there are usually two ringing machines which consist each of a single double-current machine which is arranged with two windings on the same armature, the same field serving for both windings. One winding is connected to a commutator and serves as the direct-current motor armature which is driven by the current from the battery, while the other winding terminates in collector rings and furnishes alternating current at 75 volts for ringing purposes. In some cases, instead of using the double-current machines described above, direct-connected units, consisting of a motor and a generator, are used for the same purpose.

In addition to the machines for furnishing ringing and charging current, there is also required a duplicate set of machines for supplying the interrupted current which is used for the "tone test," the "busy back," the "don't answer," and the "out of order" signals. All of these special signals require a continuous current which is interrupted a predetermined number of times per second in order that each signal may produce in the receiver a sound which is distinctly its own, that there may be no confusion as to the meaning of the different signals. For furnishing this current either a machine with a double winding may be employed or a direct-connected motor and generator unit may be used. In either case the current from one brush on the commutator is led to a brush on an interrupting ring, consisting of alternate strips of conductor and insulator, before being led to the switchboard.

The switchboard should consist of at least three panels, one for the charging apparatus, one for the auxiliary machines (the ringing and signaling apparatus) and one fuse panel on which are mounted the fuses in the different circuits as will be explained later. The charging panel should contain the main switches for the motors and generators, the overload circuit-breakers, which are in the positive side of the motor circuit, the motor-starting boxes, the generator field rheostats, and the fuses in the motor and charging circuits. In addition to this apparatus, the panel should be equipped with an ammeter for measuring the charge and discharge of the battery and a voltmeter and voltmeter switch arranged to measure the voltage at charge, the voltage at discharge and also the voltage of each individual cell of the battery. The panel for the auxiliary machines should be equipped with the main switches, starting boxes and field rheostats, the necessary fuses, and double-pole, double-throw switches arranged for throwing either group of machines upon the ringing or signaling bus-bars as necessity requires. The third or fuse panel performs a most important function, as it is on this panel that are located all of the fuses in the cord circuits, the ringing circuits and other auxiliary circuits which lead to the switchboard. On the back of this panel are arranged a number of sets of bus-bars connecting to the storage battery, to the ringing machines and to the signaling machines. These rear bus-bars are in turn connected to polished copper bars on the front of the board, the front bars being drilled and tapped for screws which hold the fuses in place. On either side of each bar is arranged a row of connectors which have a screw terminal on their front face and a lug on the rear of the board to which the wires leading to the various circuits may be soldered. The fuses are placed on the front of the board between one of the screws on the bus-bar and one of the screws in the row on either side of the bar. Each cord circuit has two fuses, one for the front and one for the back cord, and the fuses are so numbered on the front of the switchboard that the cord circuit may be readily identified. It is not customary to run a separate set of ringing leads to each position, but rather to connect two positions on each ringing circuit, allowing one position to intervene between each two so connected, so that there will be half as many ringing fuses on the switchboard as there are positions in the central office. In the same way the tone test circuits, the busy back, the don't answer and the out of order circuits are run from the fuse panel, there being two positions on each circuit. The connections to the lugs on the back of the board are made by sewing up the outgoing circuits

in the form of a cable and fanning out the terminals on either side, so as to connect by means of a soldered joint to the lugs, there being one such cable for the ringing circuit, one for each auxiliary circuit and usually several for the cord circuits. These latter are carried directly to the repeating coil rack, where their terminals are connected to the proper terminals of the coils.

The switchboard is preferably located in the wire chief's room, in as close proximity to the testing desk as possible, in order that the wire chief or his assistant may hear if possible the blowing of a fuse and in any event upon receiving a report of trouble in any circuit, may be able to see immediately from an inspection of the switchboard whether the trouble is the result of the blowing of a fuse. In addition to the circuits already mentioned, the trunk circuits are also fused on this panel, and it requires no great stretch of imagination to see that in a large office more than one fuse panel will be absolutely necessary. The addition of a recording ammeter to the switchboard equipment is of considerable value as furnishing a check upon the peg count and upon the estimated current consumption; it adds largely to the information needed by the engineering and operating departments of a telephone company.

Switchboard panels in telephone offices differ as widely as do those in power plant service. They may be made either of white marble or slate and are usually mounted in an angle iron frame which is bolted to the floor and is held in place by rods or angles fastened in the wall. The switchboard for the exchange generator is not as a usual thing located in the same room, or indeed in the same part of the building, as the rest of the apparatus. This board should consist of one panel containing a voltmeter, an ammeter, a circuit-breaker, a field rheostat, the necessary fuses, and a double-pole, double-throw switch. The leads from the generator should be connected to two of the terminals of this switch and the outside source of supply to two other terminals, the two central terminals being directly connected to the switchboard in the wire chief's room. By this arrangement it is possible to at once change the source of current from the inside to the outside supply or vice versa, this being a sufficiently flexible arrangement to provide for most emergencies.

The charging of the batteries is usually done either at night or in the early morning during a period of light load, as with a heavy demand upon the battery for current there is as a general thing some disturbance which manifests itself in the form of a buzzing noise on the subscribers' lines when the batteries are being charged, and consequently it is customary to confine the charging as far as possible to times when the exchange load is light.

Should trouble occur in the storage battery it is quite possible to supply the current to the switchboard bus-bars directly from the charging generator, and by inserting a choke coil of low resistance and high impedance in the circuit the variations of potential in the current furnished by the generator can be smoothed out sufficiently to allow the exchange to operate during an emergency. The batteries themselves are usually located in the wire chief's room and close to the switchboard. Owing to the sulphuric acid fumes which are given off when charging, they are usually enclosed in a wooden cabinet which is kept sealed as tightly as possible and which is provided with a ventilator for carrying off the fumes to the outside air.

TABLE I.—Cost of Power Plants Based on Number of Originating Calls.

Originating calls	7200	9000	13500	27000	36000	50000	65000	80000	100000

Ringers	450	450	450	450	450	450	450	450	450
Total	4450	4450	4450	5000	6400	7210	8900	9441	10381

The charging machines are usually of sufficient size to warrant being set on a foundation of their own, while the auxiliary machines being of small capacity and small size are usually grouped on an angle-iron support or table which raises them to a level of about three feet above the floor, so that they may be readily inspected and repaired. The cables from the battery to the switchboard and from the machines to the board are run in iron conduit which is laid under the floor, the power room floor usually being of concrete and the conduits being put in place before the floor is laid, the cables being pulled in later. Where the telephone exchange is located in a building which is used entirely for the purposes of the telephone company and where the building is of sufficient size to warrant the installation of an isolated plant for lighting, the question as to the advisability of installing a boiler plant and driving the generators by means of steam engines is oftentimes one that requires little consideration for its settlement. The exhaust steam may be utilized for heating and where this is not sufficient, live steam may be added to make up the required amount, and the boiler plant fulfills several functions. There are a number of telephone companies operating at the present time a steam-electric plant in their office and exchange buildings, the plant not only furnishing the power for lighting and charging the central office storage batteries, but also utilizing the exhaust steam for heating as outlined above. A typical plant of this kind consists of probably 200 horse-power in water-tube boilers, two direct-connected steam-electric units of from 60 to 80 kilowatts, one unit being run continuously and one held in reserve. The engines are usually of the simple high-speed type running at from 250 to 300 r.p.m., and the generators direct-current machines with voltages ranging from 110 to 220. With a plant of this kind the telephone company can be independent to a very large extent of any outside source of power and at the same time can utilize any other existing source of power in case of some unforeseen emergency. There is one requisite in connection with telephone service that is of prime importance, and that is continuity of service, and almost any precaution which may be taken toward this end will be justified by the results obtained.

The figures given in Table I show the size of the plant necessary for an office having a given number of originating calls, and also the cost of the various items which go to make up the equipment and the cost of installing the machinery. The size and type of the storage cells are given according to the standard of the Electric Storage Battery Company. It will be noticed from this table that the ampere-hours required per call do not agree with the figures given in the early part of this article, this being due to the fact that the former figures include only the current used in the talking circuit, while the figures in the table include all the current which is drawn from the battery for talking, signaling and operating purposes.

AUTOMATIC BLOCK SIGNALS.

BY RALPH SCOTT.

Standard Electro-Gas Signal Construction.

The standard Hall electrogas signal, which is recognized by most signal engineers at the present time as the very highest development of the automatic semaphore signal, was first placed in service on the Lehigh Valley Railroad at Buffalo in the early spring of 1902, since which time it has been giving excellent service. The general design of this signal is somewhat similar to that shown in Fig. 65.

The only similar signal in operation, up to this time installed, was the electropneumatic signal, which is operated directly by pneumatic power, the valves allowing the air to exert its pressure upon the semaphore cylinders; these valves being operated by electromagnets. The advantage of this type of signal was the direct reciprocating motion, and the enormous power, which was not readily overcome or diverted by the ordinary difficulties met with in signal service. The disadvantage of this type of signal, however, was the great initial cost of the air pipes and compression locally and the signals themselves being entirely isolated, and independent of all other signals installed. This rendered unnecessary a central point or station from which the power was distributed over a necessarily limited area to the signals. A disadvantage, however, of the motor signal

was the fact that a large amount of gearing was necessary to transform the rotary plant, and the liability of the moisture contained in the air being deposited upon the valves or small outlets, and the consequent

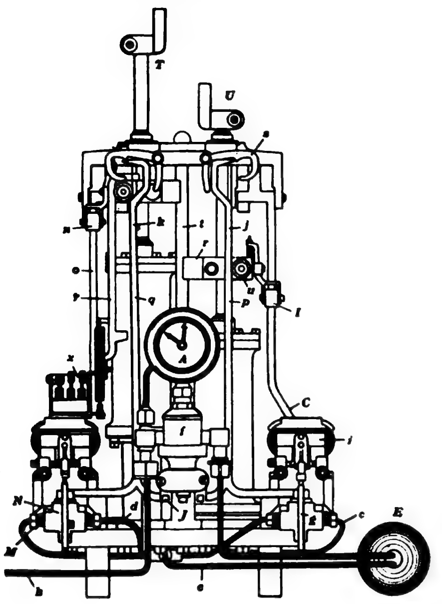

FIG. 67.

freezing at these points in very cold weather.

These facts led to the almost universal adoption of the electric motor signal, which although not as powerful as the electropneumatic, was much more to be depended upon, the power in this case being applied motion of the motor armature into a direct reciprocating motion for the movement of the semaphores.

Also, on account of the low voltage of the circuits employed, it was a very simple matter for the brushes to become insulated from the commutator, either by a thin layer of dust or frozen moisture or by the contact of the brush upon one of the mica bars insulating the commutator. Thus, the advantages of the electric motor signal were gained through the acquisition of a number of inherent difficulties.

One of these difficulties appears in the electrogas signal, which combines the great reserve power of the electropneumatic with the simplicity and isolation of the electric motor signal. The power for operating the electrogas signal is liquid carbonic acid gas, which is a very familiar and simple means of obtaining great power.

On account of its extensive use for soda water and other purposes, it is comparatively inexpensive and capable of being readily transported. It can also be stored for any length of time without the slightest depreciation. It has also a very high expansive power, which may be easily regulated by special valves.

The expansion is not attended by any precipitation of moisture. In fact, the greater the expansion the greater its ability for drying any moisture which may be present. Especially is this true when exhausting; any moisture which happens to be deposited in the pipes through which it passes being rapidly absorbed, and thus fortunately removing one of the greatest difficulties that has been met with in any type of signal—that is, the liability of clogging the moving systems by the freezing of the moisture present.

With these objects in view, it is very evident that liquid carbonic acid gas forms an ideal motive power for a mechanism that is intermittently operated, but which must be absolutely accurate in these operations.

One of the greatest difficulties which was met with in forming the electrogas signal was the construction of a valve which would not allow the gas at the comparatively high pressure at which it is used to leak through these valves at the time that the signal was not in operation.

A section of one of these valves as actually constructed is shown in Fig. 71.

The construction of the electrogas signal requires the same standard accessories as do all forms of motor signals.

The flasks employed are about 4½ feet long and 8½ inches in diameter. These

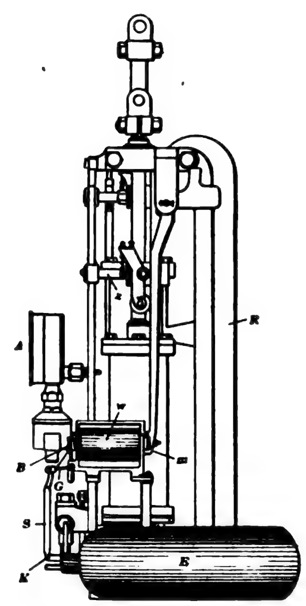

FIG. 68.

flasks are placed in the ground at the base of the signal, in an iron chute. When fully charged they weigh about 150 pounds and contain approximately 50 pounds of liquid gas. The pressure in a newly charged flask is about 800 pounds per square inch, which, however, is reduced through the reducing valve to about 40 pounds, which is the pressure required for signal operation.

To prevent the explosion of a flask when left in a heated position or during rough handling, they are provided in their upper extremity with a safety valve which releases at 2400 pounds pressure. If the flask were left near a locomotive boiler or in the hot sun, this safety valve would operate.

The actual construction of the most approved form of electrogas signal is shown in Figs. 67, 68 and 69. In Fig. 67 a front elevation of the mechanism required for the operation of two semaphores, which is the case with the home and distant signal is shown. The semaphores themselves and the signal pole are not given in this view, the rods connecting with the signal arms through a long vertical rod. The vertical cylinders are the means through which the power is applied to the movable piston, which moves the semaphores to their clear or danger positions.

The cylinders themselves are movable and are fastened directly to the rods operating the semaphores, the piston being rigidly fixed to the base of the mechanism frame. The gas which enters through the small pipe in the center of the piston causes the cylinder to move upward, thus placing the signal semaphore to the clear position. The gas is admitted to the working cylinders by means of a valve which is operated by an electromagnet. These electromagnets are energized by means of current taken directly from the track in the usual manner, forming virtually the track relay and controlled only by the track circuit.

The magnets for the home and distant signals are shown respectively at the right and left of the elevation. When the signal has been moved to the clear position, it is held in this position by means of curved levers and latches which are held in place by the relay itself. The distant signal is cleared after the home signal has been moved by means of a switch which is operated by the movement of the levers fastened to the home signal.

In Figs. 68 and 69 the mechanism of this signal is shown, which represents a partial section and side elevation. A frame, *R*, forms the housing for the cylinder and piston, *a*, the pedestal, *b*, supporting this piston; through the center of which the pipes *c* nd *d*, supplying gas to the cylinder pass. The pipe, *e*, leads from the reducing valve, *f*, directly to the expansion chamber passing from the latter to the valves *g*, which are electrically controlled; that is, through the armatures of the relays. The pipe, *h*, connects the supply tank directly to the reduring valve; the armatures, *i*, of the relays operating the valves, *g*, by means of *S* and the other connections shown in Fig. 68. The latch, *l*, which is shown in section, holds the signal clear by engaging with the clutch lever.

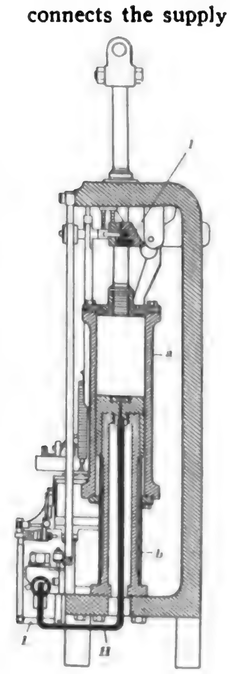

FIG. 69.

The clutch armature is shown at *M*. *n* and *I* are two buffer levers which prevent this clutch lever from striking the magnet ends when the signal passes to the danger position. They also hold, at a short distance from the poles of the magnets, the clutch armature, which prevents the signal while at the danger position from freezing fast in case moisture condenses on these clutch armatures in cold weather.

The levers, *p* and *q*, are for the purpose of

cutting off the supply of gas from the working cylinder, and also for allowing it to escape when the signal has reached the full clear position. These levers are controlled by means of the pawls, *s*. The clutch casting, *r*, is rigidly fastened to the cylinder rod so that the stroke of the cylinder will not be changed after being set. It also carries the roller, *u*, which engages with the pawl *s*, when the cylinder has reached the upper position, and thus cuts off the gas, the amount of movement of the cylinder being dependent upon the position of the clutch casting, *r*.

The front armatures of the magnets, *W*, operate the gas valve, the rear valve holding the signal in the clear position through the long lever shown. The electric switch, *X*, which is placed on the top of the left-hand magnet, is operated by the rod, *y*, whenever the latter is engaged by the stud, *z*. This switch is not shown in the front elevation. The gauge, *A*, on the reducing valve, *f*, is provided with two pointers, which move over two different dials, and indicate respectively the pressure in the supply tank and the pressure at which the signal is operated, which, as stated before, is in the neighborhood of 40 pounds.

When the signal is moved to the clear position, the magnets, *w*, become energized, the armatures, *B* and *I*, being attracted, thus opening the valve by means of the connections, *G* and *S*. The exhaust valve (refer to the section shown in Fig. 71) is then forced against its seat, the supply valve at the same time being opened, thus allowing the gas to enter the cylinder through the pipe, *H*.

This causes the cylinder to move in its upper position and puts the semaphore at the clear position.

As soon, however, as the latch, *l*, has moved past the toe of the clutch lever, *k*, the roller, *I*, raises up the pawl, *s*, thus allowing the cut-off lever, *q*, to move to its lower position. This cut-off lever being engaged with the nut, *J*, forces downward the links, *K* and *L*, thereby opening the exhaust valve, *M*, and closing the supply valve, *N*. The entire weight of the moving signal is now exerted upon the latch, *l*, at which position it is engaged with the clutch lever, being thereby held in the clear position, by reason of the energization of the clutch magnets, which hold the armature, *m*.

The switch, *X*, which reverses the current in the magnets after the signal has moved to the clear position is operated by means of the stud, *z*, thus raising the rod, *y*, and moving through an arc the switch shaft, which thereby changes the contacts. When the contacts become de-energized, as will be caused by the entrance or movement of a train in the section to which they are connected, the armature, *m*, is released, thus allowing the clutch lever, *k*, to move backward, and causing the latch, *l*, to pass the toe of the lever. This allows the signal to drop to the danger or the stop position by gravity.

As soon as the check valve, *Q*, shown in section in Fig. 71, has been partly closed, the cylinder acts in the same manner as a dash-pot, the exhaust gas at the same time bleeding through the narrow port, and bringing the signal gradually to a position of rest.

The purpose of the expansion chamber, which is connected immediately between the reducing valve and the valve controlled by the magnets is two fold; first, it allows the gas coming from the flask to expand to a lower pressure, before passing through to the cylinder, and thus by reducing the consequent pressure, allows its expansion to be more fully used. Second, it decreases the liability of the gas from taking heat before passing to the controlling valve, and thus causing the condensation or freezing of any particles of water which might be present.

The slow expansion, on the other hand, does not utilize much heat, but more evenly distributes the difference in temperature. If, however, freezing should occur, the frozen water is in a very finely divided state, which usually does not prevent the movement of the cylinder.

The area of the piston itself is five square inches which, therefore, produces a pressure in the direction of motion of 200 pounds, which also allows a large margin for the prevention of motion of the semaphore by sleet or frost. By increasing the working pressure at the reducing valve, this margin may be increased to any desirable figure. A fifty-pound charge will produce about 12,500 signal movements.

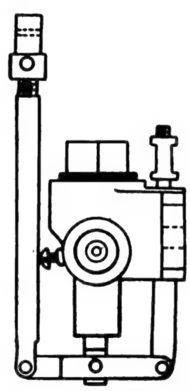

FIG. 70.

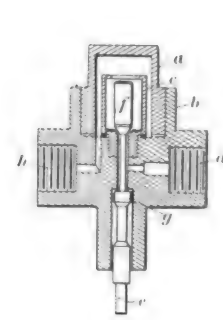

FIG. 71.

As we have already shown, the relay magnet performs two functions: first, holds the magnet clear; and second, operates the valve which controls the admission of gas to the cylinder. The amount of energy required to perform both these functions is very small, and seldom, in any case, exceeds 1/10 watt.

Less energy is required to hold the signal at clear, owing to the great leverage of the clear position armature, and to the fact of the winding on the magnets being double. These windings are connected in series, to hold the signal at clear, and in multiple, when the operation of the valve is required. This change in connection is brought about by the levers, which act upon the reversing switch.

When the signal is used in connection with the polarized relay or wireless track circuit system; when one of the windings is disconnected from the batteries, it is immediately short-circuited, the self-induction of the core thus preventing the magnet from being demagnetized, thus holding the armature for a short time before being released. This holds the signal at the clear position sufficiently long to prevent the signal mechanism from moving to the danger position when the polarity of the track system is changed.

The arrangement of a three-position signal movement is somewhat similar to the home and distant arrangement above described, a walking beam being introduced, with the utilization of only one signal rod. When the home signal is cleared, the blade moves at an angle of 45° with the signal post; and if the distant signal moves to clear, the walking beam, by an increase in leverage, moves the signal rod parallel with the signal post or at an angle of 90° with the danger position of the signal.

One of the greatest advantages of the electrogas signal is the steadiness and extreme rapidity with which it moves to the clear position. The time consumed varies from one to two seconds, according to the amount of gas which is allowed to pass the valve, this amount being adjustable.

The semaphore movement, when compared with the electric motor signal, of which the power applied decreases as the rotation of the armature increases, is much more uniform. The battery current, which is necessary to operate the clutch magnets, is .018 ampere, after the signal has moved to the clear position. Two windings, as above stated, are provided in the clutch magnets — the high-resistance winding, which is obtained by connecting the windings in series, is used to hold the signal in the clear position and the low-resistance winding obtained by connecting the windings in multiple is used to clear the signal by operating the valves, etc.

In the light in which the electrogas signal is considered, it seems fair to assume that before long either this signal or a modification of it will be used by nearly all railroad systems as standard.

Gas Valve.

An end elevation of the valve employed in the electrogas signal is shown in Fig. 70. To more clearly describe the parts of this form of valve a section is given in Fig. 71. The lever from the armature of the electromagnet is connected to the valve stem, *f*, at the end, *e*. The end, *h*, connects, by a short pipe, to the reducing valve, which in turn passes to the gas flask. When the armature of the relay is attracted, the end *f* is raised from its seat, thus admitting gas from *h* to the chambers, *a* and *c*.

At the same time the exhaust valve is closed by the action of *g*, which moves against its seat. Gas then passes from the chamber, *a*, to the threaded end, *d*, which passes to the cylinder of this signal. When *e* returns, on the cessation of the current in the relay, the exhaust is started at *g*, thus allowing the air to pass from the signal cylinder. At the same time, the admission of air is prevented by the closure of *f*. The pressure of the gas holds *f* in its lower position until overcome by the movement of the relay armature.

Abstracts from Foreign Contemporaries

Blow-off Cock for Boilers.—*Engineering* describes the simple form of blow-off cock for boilers shown in two views by Fig. 1, one being a vertical longitudinal section and the other a sectional plan. The following advantages are claimed for the

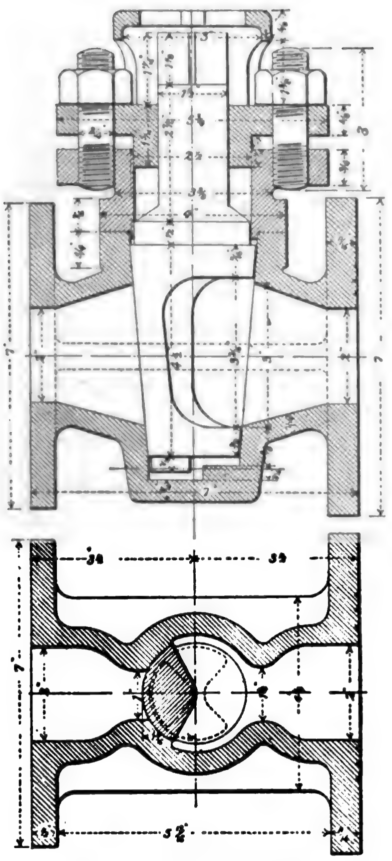

FIG. 1.—BLOW-OFF COCK.

cock: (*a*) When shut, none of the working surfaces are exposed to the water in the boiler, and, therefore, no dirt or scale can be deposited on them, and there is no scoring of the faces, no leakage, and no stiffness of action; (*b*) the gland is compound, the stuffing-box being formed by a detachable part, which is bolted to the body of the cock, thereby enabling the packing to be renewed while the boiler is under steam. (*c*) There is a safety lock which prevents the key from being removed unless the plug is properly closed. It will be seen on reference to the illustration that the advantage (*a*) is secured by cutting away the plug on the boiler side, so that its wearing surface does not extend beyond the wearing faces on the casing, the casing being enlarged in bore beyond its faces, which extend no farther than the solid part of the plug, when the latter is closed. The cocks have been extensively used both on high and low-pressure boilers.

Automatic Insulation Testing Device.—The London *Electrical Review* describes an automatic insulation testing device, the arrangement of which is shown by Fig. 2 herewith. The apparatus is applicable to all installations where both conductors are insulated, whether direct current or alternating current, and may also be used in central power stations to supplement or replace the Hopkinson two-lamp indicator, whose function it closely parallels. The current from the supply mains passes through conductors, of which a few turns are wound round the ends of a glass tube, *T;* the tube contains a liquid upon the surface of which a float, *F,* supports a small magnet, *M,* a guide, *G,* preventing the float from clinging to the side by capillary attraction. A disc, *D,* is attached to the float, to indicate its movements. The float is controlled by a magnet, M^1, so as to stand normally central when the insulation of the circuit is unimpaired, the currents in the coils neutralizing one another's action. If now a leakage occurs on either side of the system on the leads, *s* or s_1, whether a load is on or not, the go and return currents in the coils will no longer be equal, and the float will be attracted toward that side on which the leakage occurs, the displacement being approximately proportional to the magnitude of the leak, and being permanent so long as the leak exists. Directly the leak is removed, the float returns to the mid-position. If both sides of the circuit are faulty, the float will move toward the

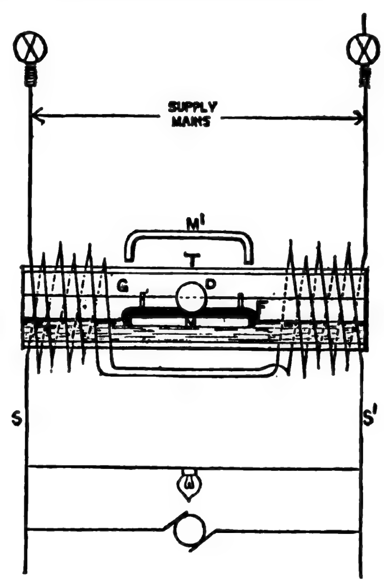

FIG. 2.—INSULATION TESTING DEVICE.

side on which the greater leakage exists—the case of exactly equal leakage of any material magnitude is so unlikely to occur for any length of time, that it need hardly be considered. An alarm signal or automatic cut-out can, of course, be easily operated by contacts made by the float at suitable positions in its travel. The apparatus is very simple, and not likely to get out of order. A model of it was appreciably affected by an artificially-produced leakage of 1-40 ampere, and obviously a growing leak would be distinctly indicated long before it attained a magnitude capable of doing injury.

Electromagnetic Relay for Voltage Regulators.—The *Elektrotechnische Zeitschrift* contains an interesting article on an electromagnetic relay for voltage regulators. The new arrangement for direct current, shown by Fig. 3, is described. + and — are the two points where the voltage is to be held constant. m_1 and m_2 are two electromagnets and the resistances, w_1

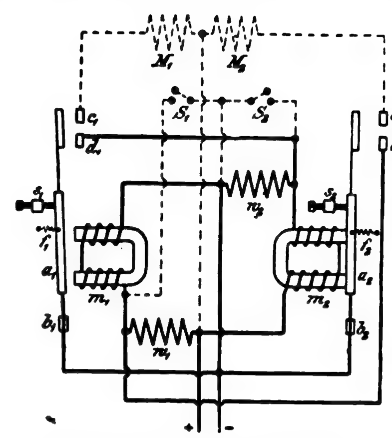

FIG. 3.—ELECTROMAGNETIC RELAY.

and w_2, are inserted between the points + and — and the windings of m_1 and m_2, respectively. m_1 is the magnet which is intended to close a contact when the voltage becomes too high. m_2 is the magnet which shall close a contact when the voltage becomes too low. The position of the different parts of the apparatus shown in the illustration is for normal voltage. The armature, a_1, is in this case not attracted by m_1, and is pressed by means of the spring f_1, against the screw s_1, so that the contact, c_1 d_1, is broken. The armature, a_2, is attracted by m_2, and rests against the screw, s_2, while the spring, f_2, tries to draw it back. The contact, c_2 d_2, is therefore also broken. Rough adjustment is made by means of varying the tension of the spring, f_1 and f_2, more exact adjustment by means of the screws, s_1 and s_2. The adjustment of s_1 and f_1 determines the highest voltage to which the e.m.f. is is permitted to rise; the adjustment of f_2 and s_2 determines the lowest voltage to which it is allowed to fall. Should the voltage rise above the higher limit, a_1 is attracted by m_1 and connects b_1, c_1 and d_1. Thereby the switching device is supplied with current which is assumed to be operated by an electromagnet, the left magnet, M_1, being acted upon in this case. This accomplishes the desired diminution of the voltage and at the same time closes the switch, S_1. The winding of m_1 is thereby short-circuited, so that it is no longer magnetized and the armature, a_1, returns to its normal position, being drawn back by the spring, f_1, the circuit of M_1 being now interrupted. Thereby the switching device is also brought back to its normal position and the switch, S_1, is again opened and the original condition has thus been reproduced except that the voltage has been reduced, so that the armature, a_1, is no longer attracted. In case the voltage drops below the lower limit, the right hand of the apparatus operates in a similar manner.

A New Dynamo Brush.—Of recent years the tendency in dynamo brush design has been towards the production of a brush combining the sparkless collecting properties of carbon with the high carrying capacity of metal. The *Electrotechnische Zeitschrift* gives the following particulars of a new brush patented by Messrs. Svenska, of Stockholm, which claims to accomplish this combination. It is known as the bronze-carbon brush, but the mass of the brush does not consist, as the name would seem to imply, of a mixture of powdered bronze and powdered carbon, but of pure powdered graphite, of which each separate particle is first covered with a coating of copper and then with one of tin. The method employed for coppering and tinning the particles is a trade secret. After this process is completed, the powder is hydraulically compressed in a dry and cold state, and without any special binding material, into the required shape. The hardness of the brush can be varied at will during this operation. Afterward the brushes are heated sufficiently to cause the copper and tin coatings to combine and form a bronze coating. In this way every particle of graphite powder receives a coating of bronze, but the smallness of these particles keeps the material quite homogeneous. It will take a polish and is readily soldered, and also possesses lubricating qualities owing to the presence of about 20 per cent of free graphite. Tests carried out at the Government Laboratories in Stockholm have proved that the conductivity and the contact resistance of these brushes are the same as those of ordinary plate or gauze brushes. Curves connecting watts lost in ohmic resistance with the peripheral speeds of the commutator in meters per second at current densities of 1, 5 and 10 amperes per square centimeter, respectively, both for ordinary carbon brushes and for bronze-carbon brushes, show that the difference between the two types of brush is especially marked at the higher current densities. For instance, at a peripheral speed of 15 meters per second and a current density of 10 amperes per square centimeter, the loss with ordinary carbons was 34.5 watts, while with the bronze-carbon brushes, under the same conditions, the loss was only 3.4 watts. With regard to sparkless running, it has been found that the bronze-carbon brushes behave as well as pure carbon brushes, and replacing the latter by brushes of the same size and shape, but made of bronze-carbon, does not affect the running of the machine. The rate of wear of these bronze-carbon brushes is slightly greater than that of metal brushes, but, on the other hand, the wear of the commutator is much less.

Electric Driving of Wood-Working Shops.—*The Electrician* of London, in an article with the foregoing heading, gives some interesting results obtained from the use of electricity as motive power in two English wood-working shops. On account of the very intermittent character of the load in such shops electricity is peculiarly applicable, and the resulting economies are so great and readily apparent that the wonder is that any other means of driving should be at all considered. There is nothing unusual with regard to the general arrangement of the motors and driving gear, except that the motors and their starting and regulating rheostats are, of course, suitably enclosed in order to keep sawdust from interfering with the smooth working of the installation. In a Gravesend shop, there are five motors, all semi-enclosed and compound wound, with the exception of a ½-h.p. motor, which is shunt wound. The potential of the supply is 460 volts.

The circular saw bench can take any size of saw up to 3 ft. in diameter, and the maximum thickness of wood which may be cut is 13 in. This machine is driven at about 1000 r.p.m. by a 12-h.p. motor placed in a brick-lined pit underground, and power is transmitted by a 5-in. link-leather belt, this belt being completely enclosed by a wooden casing. It was found that the saw bench, when taking a 10-in. cut at the rate of 6 ft. per minute on 10 -in. by 7-in. damp pitch pine, required 13.8 brake-horse-power to drive it. The results of some further tests will be found in the following table:

Average amperes taken by motor.	Kind of wood.	Depth of cut.	Length of timber.	Time in secs.	Size of saw.
4.25	Motor and saw running light.				24 in. × 1⅛ in.
6.0	Motor and saw running light.				36 in. × 3/16 in.
13.5	Deal	6½ in.	10 ft.	25	24 in.
12.5	Deal	2 in.	7 ft.	7	24 in.
11.3	Pitchpine	5 in.	6 ft.	15	24 in.
18.7	Deal	9 in.	6 ft. 6 in.	43	36 in.
12.5	Deal	3 in.	5 ft.	8	36 in.

The tenoning machine is driven at 2700 r.p.m. by a link belt from a 5-h.p. motor running at 1200 r.p.m. This machine can do various kinds of work, according to the tools with which it is fitted at the time. When running light, its motor took 5.5 amperes, and when the machine was tenoning pitch pine, removing 3.5 cubic inches of wood in 10 seconds, the current consumption amounted to 9.5 amperes. A planer designed for 8 in. by 24 in. planks, is driven by belt from a 5-h.p. motor running at 800 r.p.m. The planer itself runs at approximately 4000 r.p.m. The following figures are the result of some tests:

Average amperes taken by motor.	Kind of wood.	Width of wood.	Thickness of cut.	Length of plank.	Time in secs.
2.5	Motor and planer running light.				
5.5	Pitchpine	9 in.	⅛ in. under cut	8 ft. 6 in.	25
5.2	Pitchpine	5 in.	¼ in. over cut	6 ft.	20

Another 5-h.p. motor, running at 1200 r.p.m., drives a band saw and a vertical spindle machine. Both machines are driven by belt and for this purpose the motor is provided with a pulley 20 in. in length, which is supported at its extreme end away from the motor by a third bearing. The vertical spindle turns at about 4000 r.p.m., and the speed of the band saw is 4800 ft. per minute. When driving the belts only the motor took 2.4 amperes, and when driving the belts and band saw, running light, 3.5 amperes. Some test results are tabulated below:

Average amperes taken by motor.	Kind of wood.	Depth of cut.	Length of wood.	Time in secs.
5.6	Deal	4½ in.	18 in.	10
7.0	Pitchpine	9 in.	19 in.	20
3.5	Motor and vertical moulding spindle running light.			
4.75	Motor, vertical spindle and band saw running light.			
3.75	Deal	Moulding extracted in the form of a triangle, the sides being ⅜ in., ½ in. & ¾ in.	11 ft. 6 in.	20
5.5	Pitchpine	2½ × ⅛	2 ft. 6 in.	20
3.5	Vertical spindle with rabbeting cutters used for the previous test on spindle running light.			

Electricity is also employed for lighting the shops. The amounts paid by the owners for the last two quarters for energy were £3 1s. 6d. ($14.94) and £2 12s. 11d. ($12.82), respectively. Another installation somewhat similar to the one described is driven by five shunt-wound semi-enclosed motors, the service supply being at 214 volts. A band saw is driven by a 3½-h.p. motor by means of spur gearing (raw-hide pinion) and a belt. The speed of the motor is 1250 r.p.m., and the gearing is such that the band saw runs at a speed of 3600 ft. per minute. When both motor and saw were running light the current taken was 4.5 amperes. Some interesting tests carried out with this machine are recorded below:

Average amperes taken by motor.	Kind of wood.	Depth of cut.	Length of wood.	Time in secs.
9.0	Deal	6 in.	2 ft.	25
7.5	Mahogany	2 in.	1 ft.	4
10.5	Oak	4¾ in.	1 ft. 6 in.	15
10.0	Beech	2¾ in.	1 ft.	15

The circular saw is driven by a 7-h.p. motor by spur gear only, and as the gear ratio is approximately 1:1, the speed at the motor shaft, *i.e.*, 1050, is the same as that at the saw spindle. Although the bench can accommodate a saw with a diameter of 24 in., the saw in actual use is 19 in. only, and when running light requires 7.5 amperes.

Average amperes taken by motor.	Kind of wood.	Depth of cut.	Length of wood.	Time in seconds.
17.5	Deal	2 in.	6 ft. 2 in.	10
14.0	Deal	1¼ in.	4 ft. 2 in.	5
15.0	Deal	1¼ in.	7 ft. 3 in.	8
18.0	Deal	6 in.	2 ft.	20

A French vertical spindle runs at the high speed of 5000 r.p.m., and is belt-driven by a 2½-h.p. motor running at some 1300 r.p.m.

Average amperes taken by motor.	Description of work done.
5.0	Motor and spindle running light.
6.0	Sash work in deal, cut ¼ in. deep by ¼ in. wide. Length of wood 7 ft. Time 15 seconds.
7.5	Motor and machine running light, but a large cutter (3 in. in diameter) fixed to spindle.
13.0	Ditto, moulding work.

Current in this latter installation is charged for at the rate of 3d. (6 cts.) per unit, and the actual cost of electric energy during the quarter was £4 6s. 10d. ($21.08).

Regulator for Solenoids.—*Engineering* contains a patent note of a regulator for rendering more equable the movements of the cores of solenoids employed for controlling or regulating electric circuits in any of the forms of apparatus in which the movements of cores inside solenoids are employed for effecting the regulating or controlling operations. The cores or plungers of the solenoids are made a moderately close fit, and are arranged to move up and down within tubes of metal arranged within the solenoids and closed at the bottom. The tubes within which the plungers or cores move are connected at the bottom by a pipe which can be fully or partially opened by a cock. The tubes in which the cores move are partially filled with oil or other suitable liquid. The

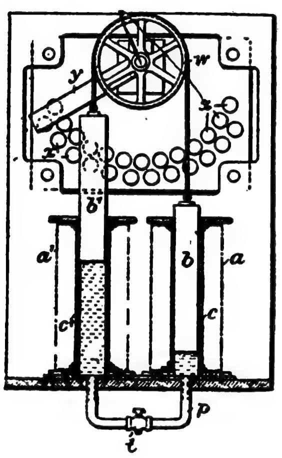

FIG. 4.—REGULATOR FOR SOLENOIDS.

damping or dash-pot effect of the arrangement may be increased or diminished by opening or closing the cock in the pipe connecting the two tubes in which the cores or solenoids move to a greater or less extent. *a* and a^1 are two solenoids which are designed to act against one another, and which respectively actuate the cores or plungers, *b* and b_1, which fit closely into the tubes, *c*, c^1, of brass, or other suitable material, on which the solenoids, *a* and a^1, are wound. The two cores, *b* and b^1, are fixedly attached to a pulley wheel, *w*, by a cord, this pulley wheel carrying an arm, *y*, which is adapted to move over the contacts, *x*, *x*, *x*, of the rheostat, and so introduce or withdraw resistance into or from the electric circuit which is to be controlled or regulated. The two tubes, *c* and c^1, are closed at their lower ends, and connected together at the bottom by the pipe, *p*, in which is the tap or cock, *t*, by means of which the flow of liquid through the said pipe, *p*, can be controlled. The operation of the apparatus is as follows: When either of the cores of the solenoids is attracted downwards, say, for example, the core, *b*, is being drawn down by the solenoid, *a*, the tap, *t*, being open, the oil or other liquid is forced through the pipe, *p*, and the tap, *t*, from the tube, *c*, into the tube, c^1, where it assists in raising the core, b^1. When the cores are moved in the opposite direction the liquid is, of course, forced from the tube, c^1, back into the tube, *c*. By opening or closing the tap, *t*, to a greater or less extent the rate of flow of the liquid can be controlled, and in this way the rapidity with which the cores move up and down under the action of the solenoids can be increased or diminished, while anything resembling violent or shock-producing movement can be completely prevented.

Lightning Arresters and Safety Devices.—The *Elektrotechnische Zeitschrift* contains an illustrated description of new safety devices made by a German cable works to prevent excessive rises of voltage. With horn lighting arresters an exact adjustment is difficult, since the arc is liable to fuse the ends of the electrodes where they are nearest to each other, and thus produce small points prolonging the terminals and thus diminishing the air-gap. The result is that the lightning arrester may begin to act slightly above the normal voltage. Moreover, with low voltages the horns must be adjusted in such close proximity that especially when they are used in the open air, water or snow may settle in the air-gap. To prevent these disadvantages a closely adjustable auxiliary arc-gap is provided, which begins to act at a voltage which may be predetermined with a high exactness. This auxiliary air-gap sends out radiation to the main air-gap between the horns and starts the main arc. Fig. 5 shows the arrangement. The main air-gap, *F*, is made larger than usual. The auxiliary air-gap, *f*, consists of a platinum point and a small platinum plate fixed at the earthed horn. The other horn (which is connected to the line, *L*) is connected with

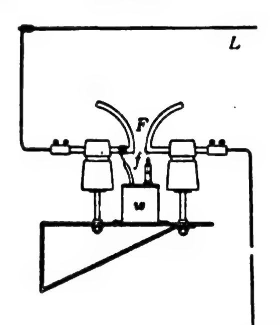

FIG. 5.—LIGHTNING ARRESTER.

the platinum point through a resistance, *w*. This resistance, *w*, is about 10,000 ohms per 1,000 volts; the object is to reduce the energy required for actuating the auxiliary air-gap to a small value. Another arrangement, which is used especially on mixed lines, consisting of overhead wires in connection with cables, is Zapf's drum. In order to protect the cable against dangerous overvoltages, this drum is provided at the point where the overhead line conects with the underground cable or at a point where the line is connected with machines to be protected; the purpose is that the fault shall be produced at this point. The drum consists of a short length of single conductor cable which is wound on an insulated drum and acts at the same time as a choking coil. The single windings of the earthed lead mantle of this cable are insulated against each other. In the conductor which earths the lead mantle a switch is provided which is opened after the accident has happened until repairs may be made. A third device described is adapted for cables only. It is similar in principle to Zapf's drum.

Some Recent Electrical Patents

Commutator Brush Holder.—Brush-holders and car couplings are patented in somewhat similar numbers, both subjects apparently having maximum attractiveness for persons of inventive minds. One of the most recent patents on brush-holders relates to the form illustrated by Fig. 1 and was issued to Messrs. William Heap and W. A. Barnes, of Bolton-le-Moors, England. The brush, *o*, is of special shape, as the illustration clearly shows, the enlarged head being adapted for clamping between a lug, *b*, which is integral with the pivoted arm, *a*, and a claw, *m'*, at the extremity of a sliding plate, *m*. This plate is drawn inward by the short end of the lever, *j*, which is pivoted to the main arm, *a*, under the influence of the helical spring, *k*. One end of this spring is seated on one leg of the pawl, *i*, which is pivoted on an arm,

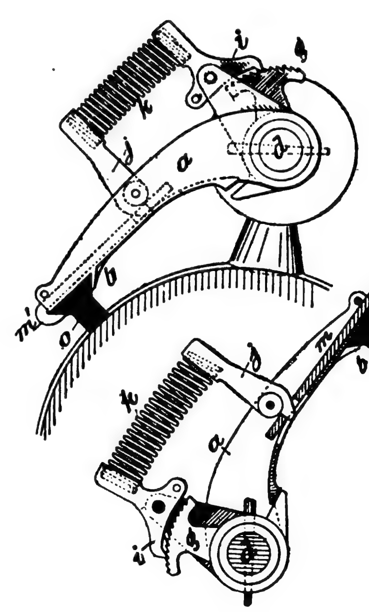

FIG. 1.—COMMUTATOR BRUSH HOLDER.

mounted on the stud, but immovably. The arm, may be adjusted about the stud (and held by the pawl, *i*) to give the desired compression to the spring, *k*, and the

latter, after drawing the claw, *m'*, solidly against the brush head, obviously presses the brush against the commutator, the arm,

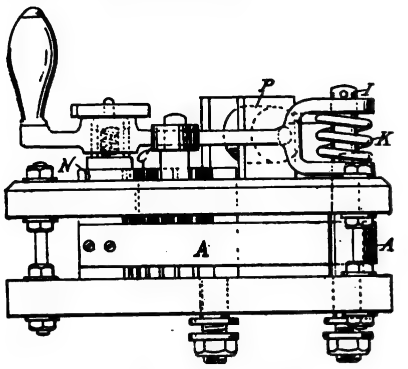

FIG. 2.—RHEOSTAT.

a, being mounted loosely on the brush-holder stud. Patent No. 781,650.

Rheostat.—The nuisance of making connection between the tap points of a rheostat conductor and the contact plates or buttons on the face plate is reduced to a very low degree in the construction patented by Mr. W. H. Powell, of East Orange, N. J., and illustrated by Figs. 2 and 3. The conductor is a continuous ribbon having its starting end attached to the central post, *B*, about which the ribbon is wound, the successive convolutions being, of course, insulated from each other. At suitable intervals the convolutions of the ribbon include in their embrace the successive contacts, *C*, with which the convolutions immediately next to them make electrical contact. The traveling brush, *N*, on the rheostat arm sweeps over the upper ends of the contact posts and cuts out the sections of the ribbon conductor in the usual manner. The conductor is enclosed in the box and the posts, *C*, protrude through the face plate to the proper height for contact with the traveling brush; this arrangement is clearly shown in Fig. 2, in which *K* is a spring for returning the rheostat arm to the "off" position when it is released by the magnet, *P*. The contacting part rests

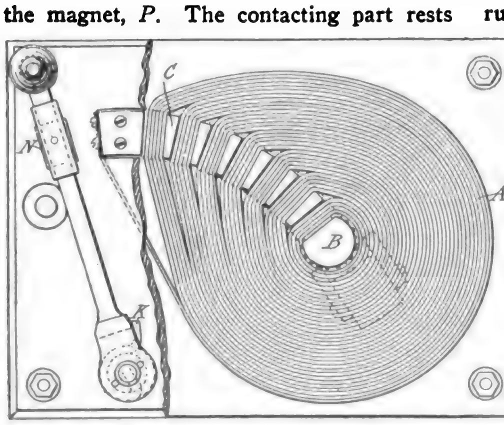

FIG. 3.—RHEOSTAT.

on the dead-block *N* which is attached to the upper slate. Patent No. 783,979.

CENTRAL STATION ENGINEERS.

VI.

Alonzo Gartley.

Alonzo Gartley was born at Cedar Falls, Iowa, on the eighteenth day of October, 1869. His early education was acquired in the public schools, and in 1886 he received an appointment as a naval cadet in the United States Naval Academy at Annapolis. In 1892 he resigned from the Naval Academy, and spent the following year with the Pennsylvania Iron Works Company as a designer of ice machinery. During the next seven years he was connected with the United Gas Improvement Company of Philadelphia as a constructing engineer and in the executive department. In 1900 he became general manager of the Hawaiian Electric Company, Ltd., of Honolulu, which office he still retains. The growth of the Hawaiian Electric Company

ALONZO GARTLEY.

since Mr. Gartley's connection with it is interesting. When he took charge in February, 1900, the plant carried a load of 390 kilowatts, 300 being in 110-volt alternating current and 90 in 120-volt direct current. There were then installed 10,500 16-c.p. incandescent lamps and about 100 horse-power in direct-current motors and no arc lamps. At the close of 1904 there were connected in circuit 31,000 16-c.p. incandescent lamps, over 600 horse-power in 500-volt direct-current motors and 220 arc lamps, and this in spite of the fact that the population, especially among the whites, had very materially decreased. Over 85 per cent. of the business is done with the white population, of whom there are about 7000 and the balance is divided among Portuguese, Japanese, Chinese, Porto Ricans, Koreans, natives and other nationalities, numbering about 33,000. Mr. Gartley is an associate member of the American Institute of Electrical Engineers, and a member of the United States Naval Institute, American Gas Light Association, and the Pacific Coast Gas Association.

TESTS OF TANTALUM LAMPS.

There appeared in the March number of the American Electrician a short description on the new tantalum incandescent lamp, recently developed by the German firm of Siemens & Halske, of Berlin. Since then Messrs. A. E. Kennelly and S. E. Whiting have made some tests on a batch of ten, the results of which are quite interesting. These lamps were all alike and of the type shown in connection with the article published last month. For purposes of comparison a 3.1-watt, 120-volt, 16-c.p. Edison carbon filament incandescent lamp was taken at random from a number of similar lamps and used. The tantalum lamps were 110-volt lamps having a normal horizontal candle-power of 25 hefner units. All of the lamps, including the carbon lamp, had frosted globes. The tantalum lamp became appreciably luminous at a terminal e.m.f. of 9.5 volts, or about 9 per cent of its normal working voltage. The carbon filament became luminous at 24 volts, or about 20 per cent of its normal voltage. Thus a tantalum filament will begin to glow at a much lower voltage than the corresponding carbon filament. This may prove a useful property in testing and the like. The horizontal candle-power of the tantalum lamp is markedly greater than that of the carbon lamp. The luminous efficiency, or candles per watt, of the tantalum lamp is also markedly greater than that of the carbon lamp tested. Thus at 110 volts the tantalum lamp consumed 2.2 watts per candle, while at 120 volts, the normal for the carbon lamp, the latter consumed 4.3 watts per candle. The normal efficiency of the frosted tantalum lamp was, therefore, nearly double that of the carbon lamp. A small change of voltage produced a somewhat larger change of the candle-power in the tantalum lamp than in the carbon lamp. Thus an increase of 1 per cent. in normal voltage produced 0.7 candle increase with the tantalum lamp, and 0.6 candle with the carbon lamp. The lamps were, therefore, nearly alike in the increase of candle-power for a given small increase in voltage, but as the relative behavior in this respect would change appreciably with a shifting of the chosen working voltages, not much stress can be laid on this comparison. Since, however, the candle-power of the tantalum lamp was considerably greater than that of the carbon lamp, it

is evident that if equal small increase in voltage produces equal increase in candle-power, the percentage of increase will be markedly less in the tantalum lamp. With frosted globes the change in horizontal candle-power with change of azimuth was negligible in the tantalum lamp. This would be substantially true in an unfrosted lamp, owing to the cylindrical disposition of the filament. In the observed distribution of a tantalum lamp in a vertical plane, at the tip the candle-power falls to about 6, the horizontal value being 18.6. The mean spherical candle-power was 13.55, which gives a spherical conversion factor of 0.73. The vertical distribution of the tantalum lamp is nearly the same as that of the common type of carbon filament lamp. The accompanying table shows a comparison of the ten tantalum filament lamps is re-

Lamp number.	Power, watts.	Horizontal candles.	Specific Consumption, watts per candle.
1	39.35	18.45	2.13
2	40.56	18.60	2.17
3	40.20	19.80	2.06
4	40.98	19.20	2.13
5	40.56	20.60	1.97
6	39.68	18.96	2.09
7	40.30	18.80	2.14
8	40.40	19.90	2.03
9	39.55	18.65	2.12
10	40.32	19.05	2.12
Mean	40.19	19.20	2.10

gard to uniformity of candle-power and consumption at the nominal voltage, 110.

NOTES.

Same Old Story; Nothing New.—An appropriation of $600,000 has been made by the Board of Aldermen of New York for the purchase of a site for a municipal electric lighting plant—the site which was to "cost the city not a penny," according to the alleged arguments of the municipal ownership advocates. It is a safe prediction that after the plant is built the feed-water for the boilers, which would otherwise be used and paid for by the Edison Company, will "cost the city not a penny"; also the water-front privileges, which would otherwise command an attractive income.

The Electric Lighting Engineers of New England.—At the annual meeting of the Association of Electric Lighting Engineers of New England, held on March 15, at Boston, the following officers were elected for the ensuing year: J. W. Lawles, of Boston, president (re-elected); W. I. Barnes, of Providence, R. I., vice-president; C. R. Brown, of Boston, secretary and treasurer (re-elected). The new members of the Board of Directors are A. E. Bliss, of Malden; W. R. Eaton, of Cambridge, and Geo. R. Stetson, of New Bedford. Messrs. W. C Woodward, of Providence; W. E. Holmes, of Newton, and E. H. Mather, of Portland, were re-elected to the board.

Entertainment Features of the Electric Light Convention.—The delegates to the convention of the National Electric Light Association, which meets in Denver the week of June 6, will be treated to a "broncho-busting" contest. The committee is making an effort to secure enough "outlaws" from the big ranches of Colorado and Wyoming to test the riding of the cowboys to the limit. The most expert riders in the West will be seen in the contest and people who have only read of the real Western cowboy will have a chance to see him in one of the most exciting features of his life. All of the committees planning the work of the convention give encouraging reports. They have set out to make the convention the best in the history of the association and the outlook for success is most promising.

An Important Water Power Project.—A company has been organized to develop an attractive water power site in Washington. It is proposed to take a body of water out of the Columbia River, in sufficient quantity to irrigate 8000 acres of land by gravitation and to furnish power to operate a hydraulic-electric plant large enough to supply a number of lumber and flour mills as well as electric railways and pumping plants for the irrigation of three tracts of fine agricultural lands. The first tract contains 70,000 acres, the second, 160,000 acres, the third, 184,000 acres. There is a fall of 78 feet from the head of the rapids to the foot, eleven miles distant. It is proposed to cut a canal 20 feet wide at the bottom and 40 feet at the top, for a distance of three miles from the head of the rapids, to bring the water out on level ground. The depth at the deepest place will be 30 feet. In building this waterway the lateral ditches and reservoir on the tract of 70,000 acres will be built at the same time work is being done on the power canal.

The engineers' estimated cost of this project is $687,000. The promoters desire information from manufacturers as to the best and latest types of machinery for this kind of work. Fuller particulars are obtainable from Mr. M. D. Kelley, post office box 384, Seattle, Wash.

Proposed Long-Distance Electric Railway or Germany.—As an indirect consequence of the famous Marienfelde-Zossen high-speed trials, a large electric railway scheme is planned by a Berlin company, which intends connecting the cities of Cologne and Düsseldorf, about 40 km. apart, by a high-speed electric railway of standard gauge. This railway, the cost of which is estimated at about 20,000,000 marks, would be designed partly after the plans of the Cologne-Bonn electric railway, which is nearing completion. The German Government is said to have abandoned for the present any idea of taking in hand the installation of electric railways, as was hoped after the Zossen trials.

Another long-distance railway is being planned by the Hamburg County Council, it being contemplated to connect Blakenese with Altona, Hamburg and Ohlsdorf by an electric railway. Part of this line is to be of special construction, and the necessary powers have been granted by the Hamburg Senate and County Council. As soon as the Prussian Diet has ratified the construction of the Prussian section of this railway, a special power station will be erected near Altona, the cost being shared by the two States of Hamburg and Prussia. The projected railway is mainly intended for securing a more rapid and frequent connection between Hamburg and the neighboring towns.

The Moutiers-Lyons Electric Power Transmission Plant.—A large power transmission plant is being installed between Moutiers and Lyons, France, by the Société Grenobloise de Force et de Lumiére, which after considering a number of projects, decided on adopting constant current transmission, at 50,000 volts. Thury electrical apparatus and material will be used in the generating and the receiving stations. The transmission line will be about 112 miles long, and 6300 horse-power is to be transmitted from Moutiers to Lyons. Part of this power is to feed by direct current of 600 volts the Lyons tramway system, while the remainder is intended to supplement the existing three-phase system of 25,000 volts constant potential. Reversible motor-generators will be provided, so that in case of necessity, the three-phase system will be able to help out the direct current system, or *vice-versa*. The primary line will enter Lyons by underground cables several miles in length, carrying direct current of upwards of 50,000 volts. This has been rendered possible by the absence of induction, resonance, etc.

The Moutiers generating station will contain at the beginning four units of 1600 horse-power each, consisting of a turbine driving two double dynamos. There will thus be eight double dynamos each capable of delivering 7200 volts and 75 amperes. The dynamos are series-wound and self-excited; they have 6 poles and run at variable speeds according to the voltage requirements, their maximum speed being 300 r.p.m. The power station has been made as simple as possible, there being no switchboard and no electrical regulating apparatus except governors, which act directly on the gates of the turbines. Each dynamo is equipped with a simple circuit-breaker, a voltmeter and an amperemeter. There is at the starting point of the line a lightning arrester equipment.

At Lyons the primary direct current is converted in a sub-station into low-tension direct current (600 volts) to be used for traction purposes. The converters are of 500 kilowatts capacity each at 428 r.p.m., and will run at constant speed. In a second sub-station there will be installed at the beginning two 500-kw. motor-generator sets, each of which comprises a constant-current machine of 75 amperes and 7640 volts maximum, coupled to a three-phase synchronous alternating-current machine. Each of these can act as either a generator or a motor. All the direct-current machinery has been so arranged as to be changed over later to 150 amperes capacity, a considerable increase in the transmitted power being anticipated.

ESTABLISHED 1889.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED
Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the
McGraw Publishing Company
114 Liberty Street, New York.

Philadelphia Office..........929 Chestnut Street
Chicago Office..........Monadnock Building
Cleveland Office..........Cuyahoga Building
London Office, Hastings House, Norfolk St., Strand

Address all business communications to AMERICAN ELECTRICIAN, *114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.*

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, draft, express or postal money order, payable to McGraw Publishing Company.

Vol. XVII. APRIL, 1905 No. 4

The AMERICAN ELECTRICIAN *has the largest circulation of any electrical journal published. Of this issue, 18,000 copies are printed. The total number of copies printed so far this year is 74,000, or an average of 18,500 per issue.*

CONTENTS.

Increasing Central Station Business.

The article on this subject, which appears elsewhere in this number, we cordially commend to the attention of central station managers, particularly those in charge of stations of medium size—between 2500 and 10,000 kilowatts maximum output ability, for example. One of the prime errors of judgment on the part of many managers of such plants is the failure to base all their calculations and plans on the fact that they have a commodity to sell which will not attract customers in many cases without some effort on the part of the seller. The men in charge of the larger stations of this country realized this some time ago, and are now carrying out well-defined policies of aggression. The Edison Companies in the largest three cities, for example, issue monthly bulletins containing convincing arguments; some of the smaller companies send out catchy circulars and employ a "follow-up" system. One progressive station manager has enunciated the doctrine that the way to get and hold business is to give the very best service that is possible and to sell fittings and supplies to your customers at almost cost. This undoubtedly goes a long way toward getting all the business that a community can give, but while it is a most sensible policy it is a limited one. There are always people who need more or less demonstration of the advantages of electric light and power, and who probably never would voluntarily inquire into the matter, and the day is long past when any manager can afford to sit down and wait for eligible customers to arrive automatically at the stage of feeling impelled to patronize the company whether or no. Even in the smaller cities where there is no competition the station output can always be judiciously increased by the proper sort of managerial policy and energy. Mr. Knowlton's article is peculiarly timely, and should be of much value to those for whom it is written.

Modern Arc Lamps.

On another page we print a résumé of present practice in arc lamp construction which can scarcely fail to interest almost every one connected in any way with the arc lighting industry. It is particularly interesting to compare, in the mind's eye, the modern types of lamp described in this article with those which were regarded ten years ago as models of perfection. All central station men of sufficiently long experience remember well enough the aggregations of complex mechanism which tried their souls in the early nineties—the "clucking" lamp with separate lift and feed magnets, the "open circuit" lamp which was damaged with distracting regularity by efforts on the part of the trimmer to pull the upper carbon holder down without releasing the clutch, and the first "constant-potential" lamp, supposed to work two in series on a 110-volt circuit, but which in reality "bucked" and "robbed" its mate so assiduously that it was regarded as a miracle when both lamps actually burned at equal brilliancy for even a few minutes. These are all now in the category with the bipolar Edison dynamo (though they never gave anything like as good service) and the notorious "Underwriters'" insulation for line-wires.

The modern arc lamp is really a marvel of mechanical development. It usually comprises merely the carbon mounts, a pair of magnet coils and a rudimentary clutch actuated through the medium of one or two links. This is especially true of constant-potential lamps; the lamps for series circuits are almost necessarily differential as to the electromagnetic action. All of them are practically as reliable as the proverbial grindstone, and when they receive anything like reasonable attention will give satisfactory service for years upon years. In the article referred to above, only those lamps which are typical of different classes of construction have been described; space limitations preclude the description of all the different makes on the market. But the reader who lacks familiarity with the details of arc lamp construction and adjustment will find practically all the information there that is necessary to a fundamental working knowledge of any American arc lamp, after locating the class in which it belongs.

Why Not Automatic Synchronizing?

The difficulty of bringing an alternating-current generator or a rotary converter into synchronism with the line and throwing it in just at the moment of exact synchronism is so familiar to every switchboard attendant who has it to do that no discussion of that particular point is necessary. Of course, it is done every day of the year, and usually without absolute "misfires" when the attendant is highly practiced, and has the "knack." But there would seem to be a good opportunity for someone to provide an automatic synchronizer which would perform the feat of coupling machines at the psychological moment and eliminate the questions of personal judgment and experience. The combination of a phase indicator and a mech-

anism the reverse of an automatic circuit-breaker to be controlled by the indicator does not appear to present any serious difficulties of construction, and the application of such a device would produce highly beneficial results in the wear and tear of machinery, not to mention the nerves of the men whom it would relieve of the task of paralleling.

Motor-Driven Wood-Working Tools.

In our Foreign Contemporaries Department this month we print the results of a series of tests made with motor-driven wood-working machinery which are of much value as far as they reach. Unfortunately, some important particulars are missing from a few of the tests, but as the matter is taken from a European paper the deficiencies could not be remedied. Among the most noticeable of those features which would scarcely have been anticipated, at least by anyone not thoroughly experienced in the details of operating wood-working machinery, is the great difference between the motor current while running idle with a given size of cutting tool and that required under the same conditions with a larger tool. For example, in the tests of a motor-driven circular saw, the motor took 4¼ amperes running light with a 24-inch saw and 6 amperes running light with a 36-inch saw. Again, the tests of the vertical-spindle moulding machine showed 5 amperes with a small cutting head and 7½ amperes with a 3-inch head, running idle in both cases. Comparing these figures with those taken when the tools were cutting, it is evident that the power taken by the machine running idle is a very large proportion of the power required while at work. This is not surprising, of course, in view of the enormous spindle speeds at which these machines run, and similar indications have been obtained by tests in this country; but it seems rather out of proportion to find the friction load going up in direct ratio to the diameter of a circular saw or a moulding cutter head.

Some tests of motor-driven wood planers recorded in this country show such figures as 4.4 electrical horse-power running idle, and just twice that amount taking a cut ⅛ inch deep and 10 inches wide with a feed of 12 feet per minute; 5 electrical horse-power running idle and 18 horse-power taking a cut ⅛ inch deep and 9 inches wide at 25 feet per minute, and so on. Tests of a circular saw 36 inches in diameter running light at 1,200 r.p.m. showed 6.4 electrical horse-power, while another saw 33 inches in diameter at the same speed took 6 horse-power running light. This apparent inconsistency might be explained by easily conceivable circumstances, but imagination balks at any attempt to conceive a reason for a friction load varying in direct proportion to the diameter of the saw.

Inductance and Reactance.

Most electrical students in their earlier attempts to master the intricacies of alternating-current theory and practice become confused by the apparent similarity of the terms "reactance" and "inductance," and are inclined to regard them as practically synonymous, like "period" and "cycle." The two terms have very different meanings, and the distinction between them should be thoroughly understood and observed. Any loop or coiled conductor possesses the property of inductance—that is, the property of inducing a counter e.m.f. in itself when a current is suddenly passed through it, or when an existing current is quickly varied in strength or cut off. The inductance of such a conductor depends entirely upon mechanical conditions; it is proportional to the square of the number of turns, in a coil; it is proportional to the area of the space surrounded by a coil or embraced by a loop; it is proportional to the magnetic conductance (permeance) of the material surrounded by a coil or embraced by a loop. It is entirely independent of the electrical conductivity of the wire in the loop or coil, and consequently independent of the total resistance; it is also independent of the strength, characteristic, variation and duration of any current that may be sent through the loop or coil.

Reactance may be due either to inductance or to electrostatic capacity; in the former case it is termed "inductive reactance," in the latter, "capacity reactance" or "condensive reactance." A coil or loop possessing a certain amount of inductance (measured in parts of a henry) will have exactly the same reactance as another coil or loop having as much capacity (in parts of a farad) as the first coil had inductance, if supplied with current under exactly the same conditions; but its reactance will have a different characteristic. Inductance chokes back the current flow in the circuit, while condensance or electrostatic capacity tends to increase it. Consequently, if a circuit has exactly as much inductance, in parts of a henry, as it has capacity, in parts of a farad, the two neutralize each other and the current will flow as though the circuit had neither inductance nor capacity.

Reactance is directly proportional to (1) the rate of change in the strength of the current, and (2) either the inductance of the circuit or the *reciprocal* of its capacity, according to whether it is an inductive or a condensive circuit. If both inductance and capacity are in the circuit and they do not equalize each other, the reactance will be proportional to the difference between the two. Without any current flowing, there is absolutely no reactance; and if there be a current in the circuit but its strength is not changed, there is no reactance. The counter e.m.f. produced by either inductance or capacity in a circuit is equal to the reactance multiplied by the geometrical average of the current strength.

The Control of Railway Motors.

The appliances for controlling railway car motors have undergone a gratifying improvement during the past five or six years, especially as regards motors on electrically propelled trains, such as those of the elevated systems. There is still lacking, however, a feature which has always seemed to us to be of importance secondary only to that of safety (which involves reliability, of course), namely, the removal of the rate of acceleration from the control of the motorman. Appliances have been worked out by means of which the motors may be started and brought up to the speed corresponding to the position of the controller handle at a rate of acceleration entirely independent of the movement of th handle, but standing passengers continue, nevertheless, to be jerked about and thrown into all sorts of grotesque attitudes whenever a motor-driven car or train is started by a motorman who feels under the necessity of "making up time." The same thing occurs when such a car or train is brought to a stop, but this is vastly more difficult to avoid; variations in acceleration due to differences in load conditions would mean merely slight losses or gains in schedule time which would probably neutralize each other in the course of a complete trip, but similar variations in stopping might cause disaster, and would almost invariably result in much inconvenience. Still, we are unable to convince ourselves that the solution of both ends of the problem is beyond the reach of modern engineers. Possibly it reduces to a question of commercial expediency, but that is a most uncomfortable hypothesis.

DESIGN AND CONSTRUCTION OF SMALL DYNAMOS AND MOTORS.

BY CECIL P. POOLE.

The Armature Winding.

Having determined the proper size for the armature conductors, the number of coils to go on the armature and the number of turns per coil, as instructed in a previous article, it remains to actually put the winding on the core and in such manner as to use the minimum amount of copper and to insure reliability. If the builder has had experience in practical armature winding, the best way to put on the winding of a two-pole machine is to follow out the old-fashioned "spiral" method used years ago on smooth-core armatures; if he is inexperienced, then the less symmetrical method of winding known as the "skip" will come easier. The spiral winding is put on as follows, assuming that the core has 32 slots and the same number of coils (two half-coils, one on top of the other, in each slot):

The first coil is wound directly into slots 1 and 15 (see Fig. 1); the next, into slots 2 and 16; the next into slots 3 and 17, and so on until the whole 32 coils are in place. The inexperienced amateur will find it almost impossible to put the winding on in this fashion without having it hump up to an inadmissible extent on the core heads. He will succeed much better with the "skip" winding. In using this type, it is only necessary to remember that the coils are put on in pairs, the two coils of each pair being parallel to each other across the heads; that the coils of each pair lie on each side of two teeth, which are precisely opposite each other diametrically; that each successive pair of coils must lie as far away as possible from the pair last put on the core, and that every coil must be put on exactly like every other coil. For example, suppose that a 32-coil armature is to be wound. The first pair of coils will go into slots 1 and 16 and slots 17 and 32; that is to say, the first coil will be wound into slots 1 and 16, laying the first wire into slot 1, from front to back, carrying it across the back head, bringing it forward in slot 16, and so on, according to the number of turns in the coil; then the armature must be turned through half a revolution in the "stocks," and the second coil wound into slots 17 and 32. The next pair of coils would go in slots 9 and 24 and slots 25 and 8, at right angles to the first pair. The next pair could go either in slots 3-18 and 19-2, or slots 31-14 and 15-30, either set of slots being as far away from the pair of coils last put on as possible. Following out this scheme of winding, the builder will usually be able to keep the heads down fairly well. Another point to be kept in mind is that the terminals of each coil must be located at the opposite side of the front head from the terminals of the other coil of the pair. Thus the terminals of the first coil, in the case just assumed, would be twisted together at slot No. 1, while those of the second coil would be located at slot 17—exactly opposite diametrically. Again the "starting" end, or the end which is made fast during the winding of a coil, should be knotted or otherwise marked for identification and the final end or terminal left unmarked.

Before putting on a bipolar winding, the core must be thoroughly insulated. The slots should be protected by troughs of varnished linen and strips of mica and the heads by discs of varnished linen. A good plan to follow is to varnish two discs of

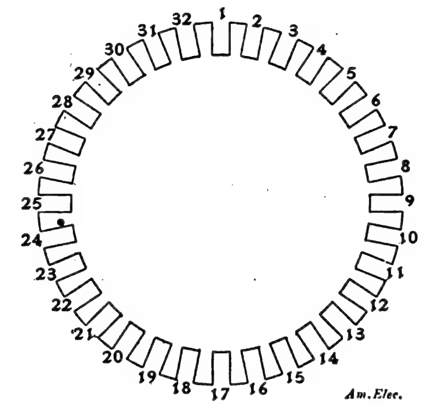

FIG. 1.

linen of sufficiently large diameter to cover the entire armature head, teeth and all, and paste them on the heads with the varnish. When they have dried thoroughly, slits corresponding to the edges of the core slots should be cut in the edges of the discs and the little flaps opposite the core slots bent down into the slots and pasted to their floors. Then a trough of varnished linen should be pasted into each slot; the ends of each trough should protrude ¼ inch or so beyond the core, slits should be cut in the projecting ends where they are creased to fit the slot corners, and the three flaps thus produced should be turned back and pasted against the ends of the core and teeth with varnish. Fig. 2 shows one of these troughs with the ends slitted as described; the dotted lines *s, s,* indicate the lines of creasing to correspond to the slot corners and the dotted lines, *c, c,* indicate where the core stops and the flaps are to be bent back against it.

After one set of troughs has been put in place, another linen disc should be pasted

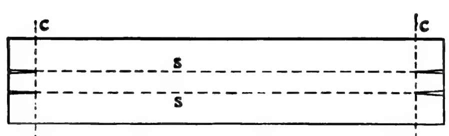

FIG. 2.

on each end of the core slitted at the edge, and the flap pasted down in the slots, like the first pair; then another set of troughs should be put in the slots; still another disc should be pasted on each end, and finally a third set of linen slot troughs. The linen should be thin, but very closely woven; the three thicknesses, varnished, should not exceed 40 mils. After the slots and core heads have been covered as described, the armature core should be baked in an oven at 120° to 130° Fahrenheit until the linen discs and troughs are bone dry; then the winding may be put on.

In winding the coils into the slots, a single thickness of varnished linen should be laid over each pair of coils at the points where the next pair will cross them, at both ends of the core. When the winding is all on, it should be thoroughly varnished wherever a brush will reach, but no varnish should be "slopped" on; it is usually best to dip the complete armature in a pan of rather thin varnish, wiping off every vestige of varnish from the shaft as soon as the armature comes out of the pan. Then the armature must be baked, as in the case of the unwound core. After the winding has been connected up to the commutator, it is a good plan to bake it again, this time by means of current sent through the winding, the armature being put in an unheated oven during the process. The current may be put through the winding by binding two contact plates to two diametrically opposite commutator segments with stout cord, and connecting the supply circuit to the contact plates. The current should not be more than 50 per cent. in excess of the rated full-load current of the armature, and the armature should be supported by blocks under the ends of the shaft and turned halfway over at intervals of fifteen or twenty minutes during the baking.

The winding of a multipolar armature is a much easier job than that of a bipolar machine. The coils are not wound into the core slots, but on two pins located at the proper distance apart; they are then pulled into shape to fit the core. The core slots must be insulated by troughs, but a single layer of pressboard 15 mils thick is ample. The troughs should be varnished, and the ends should project and be slitted and turned back as described in the case of the linen troughs of the bipolar armature. The barrels or flanges on the armature core end-plates must be thoroughly insulated, because the coils project beyond the core heads and are bound down on these flanges. Two layers of varnished linen will be sufficient; but these must be put on carefully so that no part of the periphery of the barrel is unprotected. The unwound core need not be baked.

The coils are wound, one at a time, on two pins, the distance apart of which is ascertainable by means of Rule XVII. The distance given by the rule is that from the broken line, *B*, Fig. 3, to the center of the nearest pin, indicated by the symbol, *Cp*. The sketch illustrates a three-turn coil on the winding pins ready to be tied and removed. The starting end is marked *s*, and the finishing end *f*; the successive turns are wound on top of each other, and in order to make the wire build up this way, the winding pins will have to be set into a board of sufficient width and length to give the wires support on the side, and large washers put on the ends of the pins and secured by nuts, as indicated in Fig. 4. The board carrying the pins must be mounted on a spindle, somewhat as indicated in the sketch, so that the complete winding frame can be re-

volved about its center (in a lathe, or in a pair of journals set on blocks).

After a coil is wound on the pins, the turns must be tied together temporarily with coarse linen thread; one tie thread should be used at the loop farthest from the free ends, one on each stretch of the coil, halfway between the points indicated

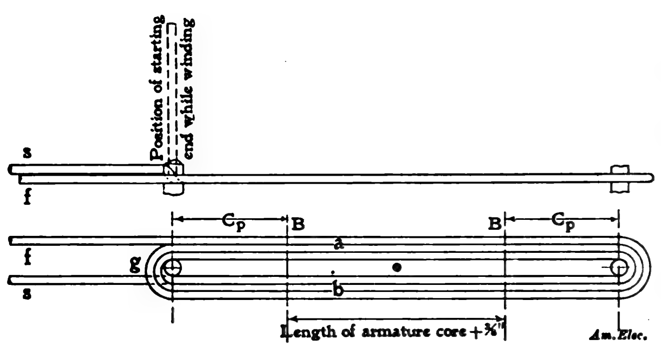

FIG. 3.

by the lines, B, B, and two at the loop, g, nearest the free ends, as near the pin as possible, so as to keep both of the ends in place. Then the nuts and washers are to be removed, the coil taken off the pins and hung on a peg until all the coils have been wound. When they are all wound they should be pulled out into the shape shown in Fig. 5, the distance between the two stretches, a, b, being just far enough to permit the coil to be pulled into the proper slots in the armature core. Before spreading the coil, each stretch of it should be securely clamped between the lines, B, B, and at the end loops; the distance between the lines, B, B, must be equal to the length of the armature core + 3/8 inch, and in order to make the coils all alike it is advisable to make the clamp jaws exactly this length. If two or more coils are to go in a slot side by side, they should be tied together as though they were a single coil, and spread. Each stretch of each coil, however, should be wrapped in a trough of pressboard 0.01

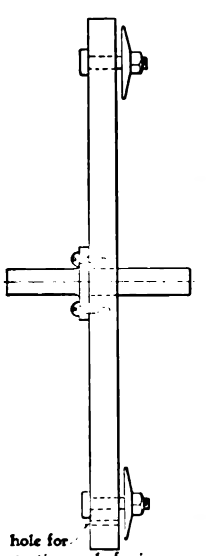

FIG. 4.

inch thick and the full length of the armature core before tying together. Fig. 5 shows a single coil spread into shape and with the terminals brought out to suit a two-path or wave-connected winding. When

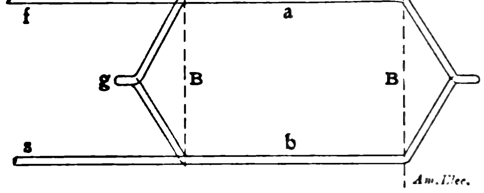

FIG. 5.

a lap winding is used, the terminals must be brought out at the loop, g, instead of at the bends.

After spreading, the coil, or group of coils if there be more than one, must be given a single wrapping of oiled linen tape 0.007 inch thick, each convolution of the tape lapping just half of the last convolution, as indicated roughly by Fig. 6. The taping must cover the entire coil, loops and all. Fig. 7 is a cross-section through an armature slot containing two four-turn coils side by side and insulated in the manner just described. After taping, the coils should be dipped in thin insulating varnish and allowed to become almost dry in air; when the varnish begins to set they should be put in place on the core. Then three or four bindings of twine should be put around the core and the projecting parts of the coils, and the armature put in the oven and baked until the accessible parts of the winding are perfectly dry.

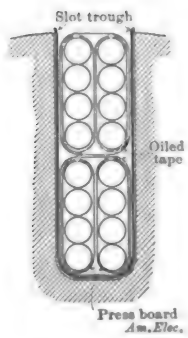

FIG. 7.

Rule XVII.—The winding pins for barrel-type armature coils must be equal to the armature core length plus 3/8 inch plus twice Cp. *To ascertain the distance,* Cp, *add the diameter of the armature core to the diameter of the tooth-root circle and multiply their sum by 0.2 for a four-pole machine or by 0.14 for a six-pole machine.*

The commutator should then be put on the shaft and the winding connected up to it. Each coil, as its first terminal is put in place in the commutator lug, must be tested for ground on the core by means of 500-volt direct-current leads from a circuit, both of the leads being fused lightly and no lamps being inserted. Before each test, care should be taken that none of the terminals of the coils is in contact with any part of the core, shaft, commutator or any

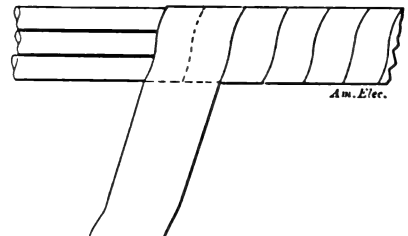

FIG. 6.

other terminal. In order to identify the second terminal of each coil, all of the first terminals having been put in their respective commutator lugs, a pair of leads from a 110-volt circuit, with an incandescent lamp inserted in one of them, should be used. After all the coils have been connected up, the winding must be again tested for grounds, and if clear, the armature and commutator must be baked for four or five hours at a temperature of about 120 Fahrenheit.

DISEASES OF ELECTRICAL MACHINERY.

BY F. B. CROCKER AND S. S. WHEELER.

Heating in Generators or Motors.

Methods of Locating and Measuring—The degree of heat that is injurious to any part of a generator or motor may be roughly determined by feeling the various parts. If the heat is bearable it is entirely harmless; but if the heat is unbearable for more than a second the safe limit of temperature has been passed, and it should be reduced in some of the ways that are given below. If the heat has become so great as to produce an odor or smoke, the safe limit has been far exceeded, and the current should be shut off and the machine stopped immediately, as this indicates a serious trouble, such as a short-circuited coil or a hot bearing. The machine should hot be started again until the cause of the trouble has been found and positively overcome. Of course, neither water nor ice should ever be used to cool electrical machinery, except possibly the bearings of large machines, where it can be applied without danger of wetting the other parts. .

The rough determination of temperature by feeling may answer in ordinary cases, but the sensitiveness of the hand varies, and it makes a great difference whether the surface is a good or bad conductor of heat. The back of the hand is more sensitive and less variable than the palm for this test. For more accurate results a thermometer should be applied and covered with a small pad of cloth or cotton waste. A standard form consists of waste contained in a shallow circular box about 1½ inches in diameter. The surface temperature thus determined should not rise more than 40 degs. C. above that of the room for any part of an electrical machine, including the bearings, but excepting commutators, collecting rings and brushes, for which 55 degs. C. rise is allowed.

The best method of determining temperature rise is by measuring the increase of resistance, but evidently it can be applied only to the coils or other electrical conductors not including the commutator. The temperature rise

$$\theta = (238.1 + t)\left(\frac{R_{t+\theta}}{R_t}\right) \text{ in which } R^{t} + \theta$$

is the resistance at the final temperature $t° + \theta°$ C., and R_t is the resistance at the room temperature $t°$ C., the standard value for which is 25 degs. C. This matter is stated fully in the *Transactions* of the Amer. Inst. Elect. Eng., Vol. XIX, p. 1075, June, 1902.

It is very important to locate the heat in the exact part in which it is produced. It

is a common mistake to suppose that any part of a machine found to be hot is the seat of the trouble. A hot bearing may cause the armature or commutator to heat, or vice versa. All parts of the machine should be tested to find which is the hottest, since heat generated in one part is rapidly diffused. It is more definite to start with the whole machine cool, after it has stood without current for several hours or over night. Any serious trouble from heating is usually perceptible after a run of a few minutes at full speed with the field magnets excited.

B. Heating of Commutator and Brushes.

This trouble, like sparking, may occur in direct-current machines, and in the types of alternating-current apparatus that have commutators already enumerated under the head of "Sparking."

Cause 1.—Heat spread from another part of machine.

Symptom.—Start with the machine cool and run for a short time, so that heat will not have time to spread. The real seat of the trouble is in the part that heats first.

Remedy.—(See Heating of Armature, Fields or Bearings.)

Cause 2.—Sparking.—Any of the causes of sparking will cause heating, which may be slight or serious.

Symptom and *Remedy.*—(See "Sparking.")

Cause 3.—Tendency to spark or incipient sparking hardly visible. Sometimes before sparking appears, serious heating may be produced by one or more of the causes of sparking.

Symptom.—The heating is reduced by applying the principal remedies for sparking, such as slightly shifting or more carefully fitting the brushes. Fine sparks may be seen by sighting in exact line with the surface of contact between the commutator and brushes. Incipient sparking due to excessive inductance in each armature section can be corrected only by reconstruction. When caused by a weak magnetic field it may be cured as explained under "Sparking," Cause 8.

Remedy.—(See "Sparking.")—Apply the remedies with extra care.

Cause 4.—Overheated commutator will decompose carbon brush and cover the commutator with a black film, which offers resistance and aggravates the heat.

Symptom.—Commutator covered with dark coating; commutator brushes and holders show signs of abnormal heat.

Remedy.—Commutator and brushes should be thoroughly cleaned, and the latter carefully fitted to make good contact at the proper points. (See "Sparking," Causes 2, 3 and 4.) It may be necessary to substitute a different kind of carbon brush..

Cause 5.—Bad connections in brush-holder, cable, etc.

Symptom.—Holder, cable, etc., are abnormally high in resistance, unusual resistance may be found in these parts by "drop method."

Remedy.—Improve the connections.

Cause 6.—Arcing or short-circuit in commutator across the mica, or across the insulation between bars or nuts.

Symptom.—Burned spot between parts; arc or spark appears in the insulation when the machine is operating.

Remedy.—Pick out the charred particles, take commutator apart and repair or put on new commutator.

Cause 7.—Carbon brushes heated by the current.

Carbon brushes require less attention than copper, because they do not cut the commutator, and their higher specific resistance usually reduces sparking, but it may also cause them to heat more than copper brushes.

Symptom.—Brushes hotter than other parts.

Remedy.—Use higher conductivity carbon. Let the brush-holder grip brush closer to commutator so as to reduce the length of brush through which the current has to pass. Reinforce the brush with copper gauze, sheet copper, or wires run through it, or use some form of the combined metal and carbon brushes that are on the market. Use larger brushes or a greater number of them so that the current density does not exceed 30 or 40 amperes per square inch of contact area.

C. Heating of Armature.

This trouble, excepting Causes 6 and 8, may occur in any direct or alternating-current machine, whether generator or motor. The two causes excepted may give trouble in direct but not in alternating-current machines.

Cause 1.—Excessive current in armature coils.—Symptom and Remedy the same as "Sparking," Cause 1.

Cause 2.—Short circuited armature coils. —Symptom and Remedy the same as "Sparking," Cause 5. See also Cause 7.

Cause 3.—Moisture in armature coils.

Symptom.—Armature requires considerable power to run free. Armature steams when hot, or feels moist. This is really a special case of Cause 2, as moisture has the effect of short-circuiting the coils through the insulation. Measure insulation of armature, which would be much lowered by moisture.

Remedy.—The armature should be baked for several hours in an oven or other place sufficiently warm to drive out the moisture, but not hot enough to run any risk of injuring the insulation. A convenient and safe method to dry an armature (or field winding) is to pass through it a current which should be regulated to be about three-quarters of the rated current, the armature being held still or turned over occasionally.

Cause 4.—Eddy currents in armature core.

Symptom.—Iron of armature core hotter than coils after a short run, and considerable power required to run armature when field is magnetized and there is no load on armature. This may be distinguished from Cause 2, by absence of sparking and absence of excessive heat in a particular coil or coils after a short run.

Remedy.—Armature core should be laminated more perfectly, which is a matter of first construction.

Cause 5.—Eddy currents in armature conductors.

Symptom.—The same as Cause 4, except that armature conductors are hotter than core even without any load.

Remedy.—This trouble is due to a difference in the e.m.f. generated on the two sides of each armature conductor. It is overcome by reducing the thickness of the conductors or by splitting them up into a number of strips or strands, which should be twisted to equalize the effects. Rounding or beveling off the edges of the pole pieces will also reduce the trouble. The usual and most effective cure is to put the armature inductors in slots or perforations in the armature core.

Cause 6.—One or more reversed coils in one part of armature, which will cause a local current to circulate around a direct-current armature.

The armature coils of an alternating-current generator or synchronous motor being usually arranged in series, the only effect of a reversed coil is to reduce the e.m.f. corresponding to a loss of two coils. It does not cause short-circuiting or heating.

Symptom.—Excessive current in a direct-current motor running free, or excessive power required to drive an alternator without load. In a direct-current motor running with considerable load, the half of the armature containing the reversed coil is heated more than the other (the opposite being true of a generator), but no individual coil is abnormally heated. If a moderate current is applied to each coil in succession by touching wires to each two adjacent commutator bars and a compass needle is held over the corresponding coils the latter will behave differently when the reversd coil is reached.

Remedy.—Reconnect the coil to agree with the others.

Cause 7.—Heat conveyed from other parts.

Symptom.—Other parts hotter than armature. Start with the machine cool and determine by thermometer or hand which parts heat first and to the greatest extent.

Remedy.—(See Heating of Bearings, Field and Commutator.)

Cause 8.—Unequal strength of magnetic poles may cause excessive current to flow in an armature, thereby heating it abnormally in the case of a multipolar direct-current machine with multiple-circuit armature winding.

The armature coils of an alternating-current generator or synchronous motor being usually arranged in series, the effect of weakening or even omitting one of the field poles is merely to produce a corresponding reduction in e.m.f. which may be overcome or avoided by slightly strengthening the other poles. No short-circuiting or heating is likely to result. (See "Voltage Too High or Too Low," Cause 2.)

Symptom and *Remedy* are the same as for "Sparking," Cause 9.

Note.—Any excess of current taken by an armature when running *free*, as a motor, whatever the cause, must be converted into heat by some defect, hence the "free current" is the simplest and most searching test of the efficiency and perfect condition of the machine.

THE CALORIMETRIC TESTING OF COAL.

BY GEORGE T. HANCHETT.

The testing of coal does not necessarily require a knowledge of chemistry and a system of manipulation beyond the range of ordinary power-house facilities. In reality a test can be conducted with very simple apparatus, and in a very short time. The necessary equipment is as follows: One pair of balances sensitive to 1 milligram, with sets of weights. This should not cost over $15; one pair of scales, capable of weighing to 1-10 of an ounce, costing about $3; one calorimeter made as per directions included in this article, which should cost about $5; and one thermometer graduated in single degrees from 32 degs. to 110 degs. Fahr. This can be had for about $2.

There should also be provided an iron mortar and pestle, a porcelain mortar and pestle, a few beakers, and some pieces of soft, loosely-woven cheesecloth.

A coal calorimeter is preferable made of sheet copper coated with tin, and can be made from the drawings by any tinsmith. It consists of an outer vessel, shown in Fig. 1, equipped with a perforated thermometer tube soldered on the inside. A bomb, which can best be made of brass tube, is also provided, the details of which are shown in Fig. 1. The vessel should be water tight, and particular pains should be taken to see that the bomb can be screwed together tightly. All joints which are not to be opened had better be soldered.

Before conducting the coal test one ounce bottle of peroxide of sodium should be secured. This is a very energetic compound, which readily parts with its oxygen and should be carefully handled. It should not be spilled loosely about or put in any place where it is likely to come in contact with water since there is a certain hazard of fire or explosion, and while such accidents at no time would be serious, they are likely to take place in the absence of the experimenter, and grow to uncontrollable proportions before he returns.

The sample of coal to be tested should be selected by taking a shovelful from many parts of the pile and heaping them together on the floor of the boiler room or by taking periodic samples from the stream of coal as it enters the bunkers. These shovelfuls should be thoroughly mingled and the pile quartered. One quarter should be selected and the process repeated until enough has been secured to fill an ordinary Mason jar, into which the coal should be put and tightly sealed.

The jar and its contents should first be weighed and a record made of it. The coal should then be spread out in a thin layer on a sheet of paper and allowed to become thoroughly dry. The process can be hastened by placing the coal in a tin baking pan and heating it on top of a hot stove until all the moisture has been expelled. As soon as it is thoroughly dried the coal should be returned to the Mason jar and reweighed. The jar should be thoroughly cleaned out and weighed also, and its weight deducted from that originally observed. It will be found that the mixture has lost weight by drying. Dividing the lesser weight by the greater the percentage of coal in the mixture will be found, the difference between this figure and 100 per cent is the percentage of moisture which is the first item of interest to the coal user.

The dried coal is now quartered and requartered as before until a sample weighing about 2 ounces is had. This should be powdered in the iron mortar to the size of rice, and again quartered until about 3 metric grams are secured. This should be returned to the iron mortar and ground to

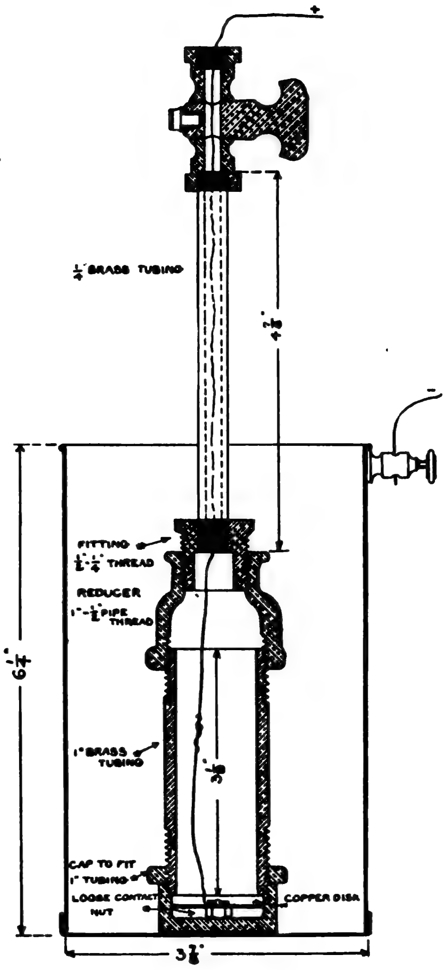

FIG. 1.—COAL CALORIMETER.

the consistency of ordinary sand. About one-half of this mixture can now be transferred to the porcelain mortar and should be ground very fine indeed. A small piece of thin cheese cloth can be stretched over the top of the beaker, and occasionally the coal can be sifted through into the beaker, the coarser particles retained by the cheesecloth being returned for further trituration. The finished sample should be as fine as ordinary flour. One gram of this is carefully weighed and mixed with 18 grams of peroxide of sodium. It is essential that the mixing be thorough and complete. The mixture is to be carefully packed in the bomb; but before it is placed in the bomb, this latter device must be made scrupulously clean and free from moisture, since any moisture entering the bomb will make a serious error in the results giving the coal a thermal value altogether too large. A flat or disc of copper must also be inserted and attached to an iron wire of about No. 34 B. & S. gauge. This iron wire should be long enough to thread through the mixture, and after leaving the same is fastened to a No. 32 copper magnet wire, which is threaded through the upper tube of the bomb and through the pet cock. The calorimeter and filled bomb should now be carefully weighed and the weight recorded and then water added to just cover the bomb. This water is also weighed. The calorimeter and bomb being made of brass and copper can be taken to have a specific heat of .095, and multiplying the weight of the metal by this a value is obtained which is known as the water equivalent of the apparatus. If the calorimeter weighs 2 pounds, the water equivalent would therefore be .190.

It will be found convenient to select a weight of water such that when added to the water equivalent of the calorimeter, the result will be an even number of pounds, and having ascertained this weight, it will be well to make a counterpoise of the proper amount which can be used for weighing in all subsequent experiments. If the even number representing the equivalent weight of the water is to be 4, the actual amount of water used should be 3.810. To this should be added the weight of the calorimeter, 2 pounds, making a total of 5.81, and a counterpoise should be made of that weight. This greatly simplifies the weighing in subsequent experiments, for it is only necessary to put the completed calorimeter on one side of the balance and the counterpoise on the other and add water until the scale balances.

If the foregoing figures have been assumed, the heat developed during the experiment can be at once translated to British thermal units by multiplying the degree rise in the thermometer by 4, which figure can be termed the constant of the calorimeter. Of course, it is plain that a similar system of reasoning could be employed to use any other even figure. Having prepared the calorimeter with its water, the bomb should be removed to preclude the possibility of slow leakage, and the water allowed to stand until it has reached the temperature of the room or nearly that. If this is done there will be little possibility of error by radiation for the difference in temperature in the calorimeter and its surroundings will be small at any stage of the experiment. When the temperatures have been thus adjusted, the calorimeter should be reassembled and restored to the scales, enough water being added to make up for any loss by evaporation, and the initial temperature noted. A bank of ten lamps should be connected in series with the wire protruding from the stop cock of the calorimeter and the calorimeter itself at the binding post provided for the purpose, and when all is ready the switch should be closed. This will heat the short length of wire imbedded in the mixture to the melting point and ignite the mixture, the ignition being revealed by smoke appearing at the orifice of the stop cock, which should be closed

at the first sign of ignition. In closing it will cut the soft piece of 32 magnet wire and effectively seal the bomb and its contents.

The combustion in the bomb will continue for about half a minute. Very little pressure will be developed as the gases evolved are rapidly absorbed by the residual salt, and it will be found when the bomb is opened at the close of the experiment that there will be no puff of gas due to the reaction.

As soon as the mixture is ignited, the temperature will rise, due to the combustion, and for about two or three minutes thereafter the contents of the calorimeter should be thoroughly stirred by means of the bomb. The maximum temperature should be noted, reading the thermometer to tenths, and the difference between the initial and final temperatures multiplied by the constant of the calorimeter, determined as indicated, will give the B. T. U. contained in 1 gram of coal, subject to the following correction.

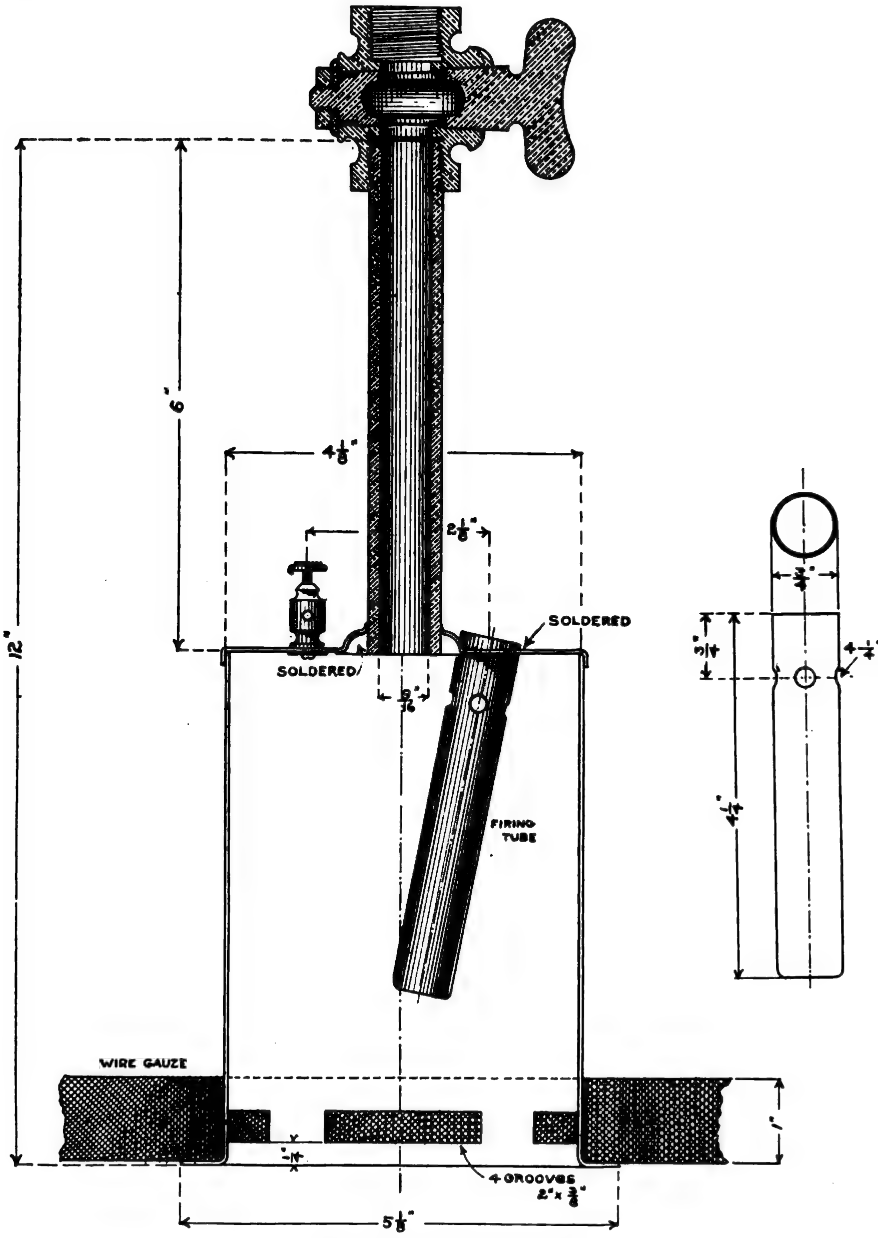

FIG. 2.—COAL CALORIMETER.

This correction is the deduction of 27 per cent. of the observed heat units, or, in other words, multiply the observed heat units by .73. This is necessary because the reaction is exothermic and generates heat, and it has been found by careful chemical test that the amount of heat generated due to chemical reaction is substantially in this proportion no matter what the thermal value of the coal, and it is sufficiently accurate for all practical purposes. At the close of the experiment a hard, greenish deposit will be found in the bomb, which can readily be removed by soaking in hot water.

Having found the B. T. U. in one gram, it is very easy to obtain the thermal units in one pound by multiplying by 453.59. If carefully done this experiment will be found to be capable of repetition and check within one-tenth of one degree, and as the rise in temperature is from 8 to 10 degs., the process is accurate to within nearly 1 per cent.

Another form of coal calorimeter may be constructed with a similar outer vessel, and with an inner vessel constructed as shown in Fig. 2. This vessel, as the illustration shows, consists of a cylinder open at the bottom and equipped at the top with a stop cock and tube. A firing tube is also provided, having holes in the upper part, and in this firing tube are packed two grams of coal, 7½ grams of chlorate of potash and 2½ grams of nitrate of potash, thoroughly powdered and mingled. The calorimeter is assembled, due correction being made for the weight of the calorimeter and the usual observations made with reference to temperatures and weight of water. The mixture is fired through the upper hole of the inner cylinder, preferably by drawing an arc at the side of the firing tube and the wire. The mixture is not readily ignitable, and several arcs may be necessary before combustion takes place. As soon as the combustion begins, the upper end of the fire tube should be sealed with a rubber stopper shod with metal. The moment the stopper is inserted, the pressure of the gas issuing through the small holes in the firing tube will depress the level of the water and presently the gas will bubble out of the bottom of the cylinder or through the small holes at the bottom covered with gauze, as shown in the figure. The escaping gases are supposed to give up their heat to the water. The initial and final temperatures are noted as before. After combustion is complete, the upper stopper should be opened or the plug removed from the firing tube. The water will then rise and come in contact with the hot firing tube and absorb still more heat, and the final temperature should not be taken until all of the heat from the reaction has been thoroughly absorbed by vigorous stirring and quenching of the firing tube as above described. This is a well-known process, but is subject to serious error. The thermal values obtained without correction are always too small, and yet the reaction is an exothermic one, and the amount of heat liberated is larger than that contained in the powdered coal. One of the principal sources of error is due to imperfect combustion, which can be corrected for by thoroughly leaching the mixture in the firing tube, carefully drying the deposit, weighing it, igniting it in a crucible and weighing again, charging the difference to unburned coal and pro-rating accordingly. Much heat is lost by the premature escape of the gases.

Another correction should be made for the heat of reaction, which is a subtractive one, and still another correction should be made for the solution of salt in the calorimeter, which changes the specific heat of the water and absorbs heat by the solution. The gases will come away in the form of white smoke, the white smoke being due almost entirely to finely powdered salt. These corrections are so complicated and are likely to be so varied that the process is very inaccurate, and occasion has been taken to describe it and set forth its inaccuracies because the process is well known, and the reader may thereby be saved a great deal of unsatisfactory experiment. The writer has made efforts to obtain a proper method of correcting the numerous errors which obtain with this device, and has found none of them sufficient-

ly reliable so that check readings within 10 per cent. can be had, and therefore will not venture any figures which may lead others into useless labor. It is sufficient for the purpose of this article that the method be described as one which the investigator is likely to encounter in his first investigations of the subject, and one which should be avoided. The first method, however, will be found to give very practical satisfaction.

COMMON BATTERY TELEPHONE SYSTEM.

BY W. S. HENRY.

The connections of a telephone system devised by Harry G. Webster for the Stromberg-Carlson Telephone Manufacturing Company, and about the same as is installed in at least one or two telephone exchanges, is shown in Fig. 1. It is a multiple central-energy, or common-battery, telephone system. At the right and left are shown two complete line circuits, including the subscribers' telephone instruments, *A* and *D*. Between the two line circuits is shown one cord circuit with which the operator connects together the line circuits of any two subscribers. The distinguishing feature of this system is the use of a differentially-wound line cut-off relay, *CO*. Furthermore, there are no coils or relays directly in the talking circuit.

At *E* is shown a visual electromagnetic line signal. As long as current of sufficient strength passes through the coil of *E*, the shutter is held up in such a manner as to readily indicate to the operator that the subscriber on that line desires a connection. When the current ceases the shutter drops by its own weight and covers the white spot or other signal. This is the normal position of the signal. The coils, *m* and *n*, of the cut-off relay have a resistance of about 200 ohms each and are so wound that when they are connected in series they neutralize each other and do not magnetize the iron core of the relay. The armature, *o*, normally rests against the stop, *c*. In the subscriber's telephone instrument, the transmitter, *T*, and primary winding, *p*, of an induction coil are connected in series with the line wire, this circuit being open at the hook switch contact when the receiver rests on the hook. When the receiver is removed from the hook this circuit is connected across the two line wires. When the receiver rests on the hook, a bell, *V*, and a condenser, *C*, are connected in series through a contact on the hook switch across the two line wires. The removal of the receiver from the hook switch opens the bell circuit. When the subscriber's receiver rests on the hook switch no direct current can flow through the bell circuit, although the bell circuit is closed at the hook switch because the ½-microfarad condenser, *C*, forms an open circuit to a direct current; but an alternating current of about 20 cycles per second, such as the current used for ringing purposes, can readily pass through the condenser and ring the subscriber's bell.

The system operates about as follows: When subscriber, *A*, removes his receiver from the hook, the transmitter, *T*, of about 40 ohms resistance and the primary winding, *p*, of about 15 ohms resistance are connected in series across the line circuit. This resistance is low enough to allow sufficient current to flow from the central exchange battery, *B*, through the coil, *m*, line *L*, winding *p*, transmitter *T*, line L^1, armature *o*, contact *c*, coil *n*, signal *E*, to cause the latter to display its signal. The current in coils, *m* and *n*, tends to magnetize the core of the relay, *CO*, in opposite directions, hence the relay is not affected and remains inert. The display of a signal by *E* attracts the attention of the operator, who inserts the answering plug, *P*, in the subscriber's answering jack. Current now

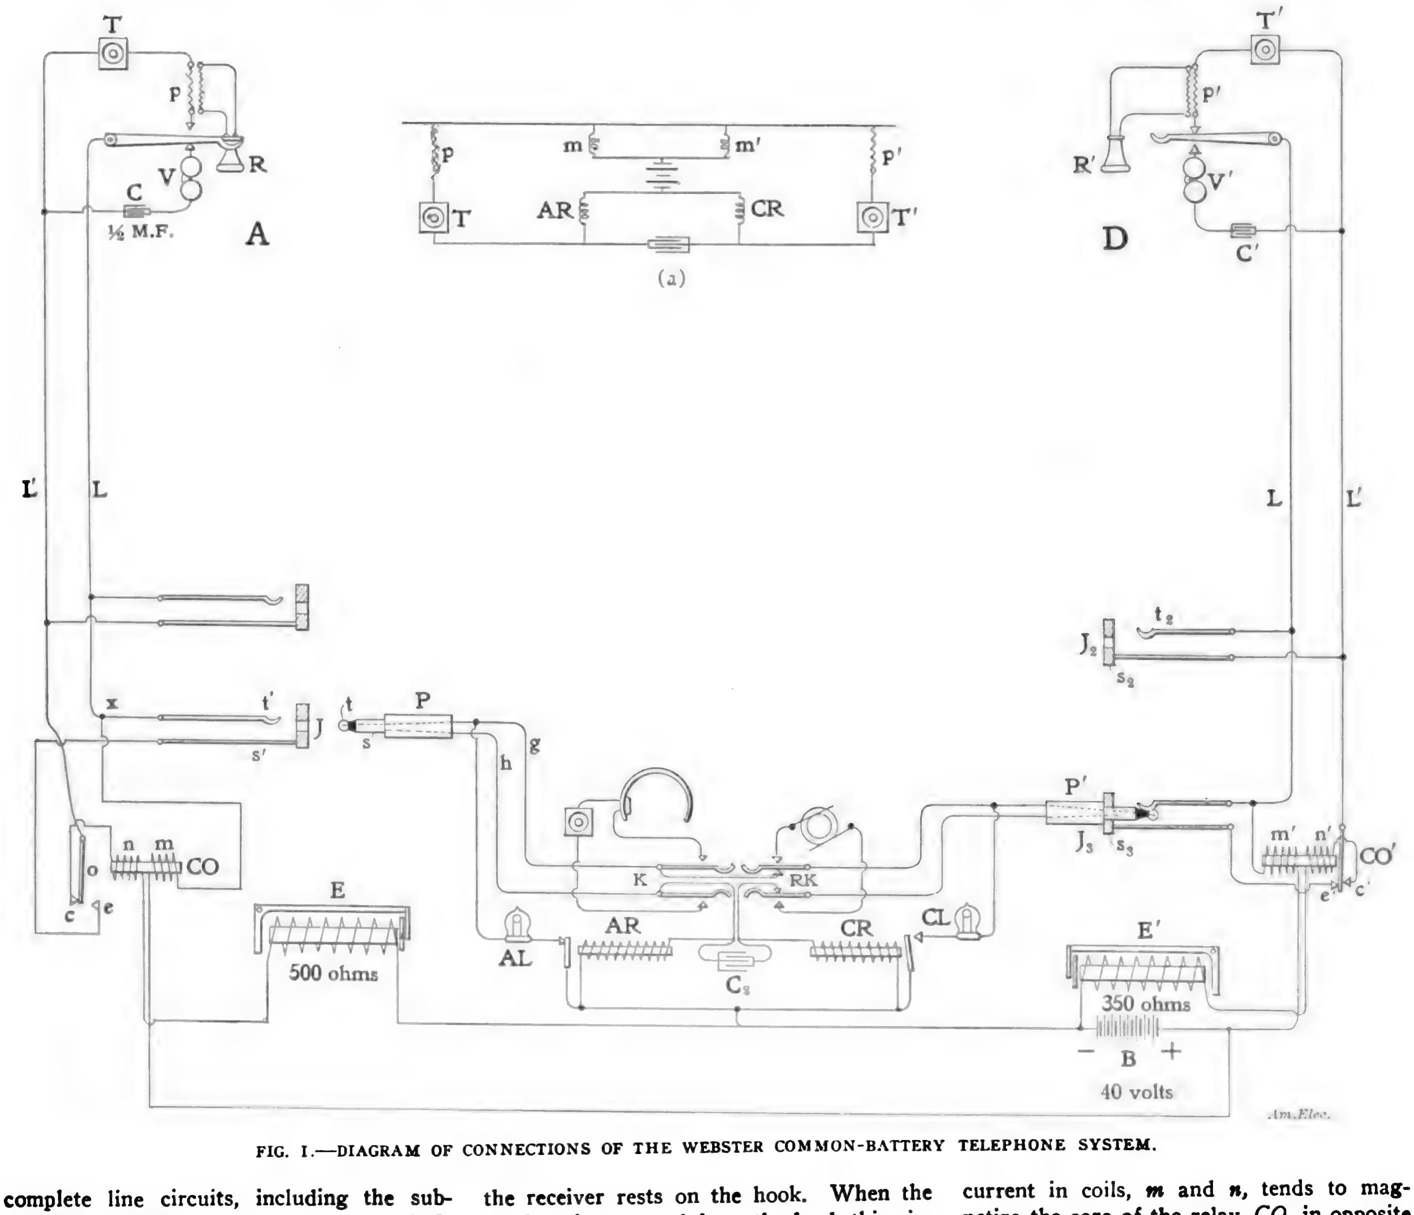

FIG. 1.—DIAGRAM OF CONNECTIONS OF THE WEBSTER COMMON-BATTERY TELEPHONE SYSTEM.

flows from *B* through *m* to *x*, where it divides, part flowing through *t'*, *t*, *AL*, and part through line *L*, winding *p*, transmitter *T*, *o*, *c*, *n*, *E*, back to the battery. The line signal, *E*, has so much higher resistance (350 ohms) than the supervisory lamp, *AL*, which is a 20-volt lamp, that the greater current through coil *m* is sufficient to energize the cut-off relay, *CO*, thereby transferring the sleeve side, *L'*, of the line from connection through *c* to coil *n* to the connection with the answering supervisory relay, *AR*, through contact, *e*. Current now flows from *B* through *m* to *x*, where it divides, part flowing through line *L*, primary winding *p*, transmitter *T*, line *L'*, *o*, *e*, s^1, *s*, *h*, relay *AR*, back to the battery, thus energizing the answering supervisory relay, *AR*, which opens the circuit through the answering supervisory lamp, *AL*, and hence extinguishes it.

The operator now closes her listening key, *K*, which connects her transmitter and receiver in series across the line circuit, and hence her transmitter circuit is in parallel with the subscriber's circuit. Both these circuits are supplied with current from the battery, *B*, which is bridged across the line circuit through coils *m* and *AR*, each having a resistance of about 200 ohms, which act as impedance coils as well as relays. The operator's listening set may be connected in the same manner as the subscriber's talking circuit or in any other suitable manner.

The operator ascertains the number of the subscriber desired, and then makes the usual busy test by touching the tip of the calling plug to the sleeve of the desired subscriber's jack. If there is no plug in any other jack belonging to the desired subscriber's line, the line *L'* will be open at the subscriber's hook switch; hence s_2, the sleeve of the jack touched, will have the potential of —*B* (through *c'-n'-E'*) and the tip of the plug will also have the potential of —*B* (through the supervisory lamp *CL*), hence there is no disturbance of the conditions previously existing and no click will be produced in the operator's receiver, and she will insert the plug in the jack. However, if there is a plug in the answering jack, J_3, or in any multiple jack, then current will be flowing from —*B* through the sleeve side of the cord circuit in use, and the sleeve of the jack in which the plug has already been inserted. Consequently, the sleeves of all jacks of the busy line will have a potential differing from that of —*B* (due to the drop of potential through a supervisory relay) and hence, different from that of the tip of the plug used in making the test; consequently, a click, denoting a busy line, will be made in the operator's receiver the moment the tip of the plug is touched to the sleeve of a busy line.

When the calling plug is inserted in the jack of a line not busy, say in jack J_2, no current can flow through the supervisory relay, *CR*, because the line, *L'* is open at the subscriber's hook switch, and there is no tendency for current to flow through *c'-n'-E'*, hence the supervisory relay, *CR*, will not be energized; but the cut-off relay will be operated by the current through *m'*, thus cutting off the line signal, *E'*, and the supervisory lamp will be lighted. When the ringing key is closed, alternating current will flow through the line, condenser *C'* (½ microfarad) and bell *V'*, and ring the latter.

When the desired subscriber takes down the receiver, current will flow from *B* through *m'*, line *L*, subscriber's coil *p'* and transmitter *T'*, line *L'*, s_2, *CR*, back to *B*, thus energizing both *CR* and *CO'*, and therefore extinguishing the supervisory lamp, *CL*.

When the subscribers finish their conversation, each supervisory lamp will light as each subscriber hangs up his receiver. For instance, if the receiver, *R'*, is hung up, no current can flow through the supervisory relay, *CR*, hence *CL* lights up and the cut-off relay remains energized until the plug is removed from the jack. When both plugs are removed, the cut-off relays will release their armatures, thereby connecting the line signals to the line wires ready to receive another call.

It will be noticed that the subscriber's receiver is in a permanently closed local circuit containing one winding, *s*, of an induction coil. Many independent telephone manufacturing companies use this arrangement successfully. An incoming voice current flows through the primary winding, *p*, and induces a current in the secondary winding, *s*, which causes the receiver to give out the proper sounds. The transmitters have a resistance of 40 ohms or more, and each winding of the induction coil about 15 ohms. On account of the high resistance of the transmitter and the fact that speaking into it will produce a large variable resistance, the total resistance of the line circuit is sufficiently altered when talking into it to produce very good results. At *a* is shown the connections that exist during the conversation. In this diagram all apparatus and connections not forming a part of the talking circuit have been omitted.

Demand Meters in Boston.—The Edison Electric Illuminating Company, of Boston, which began in 1898 to experiment with the Wright demand system of charging, is now making as rapidly as possible a final extension of the system to all its customers, both for light and power. Hitherto the Wright demand indicator has been used by the company for installations of fifteen lights or more (the demand of customers having less than fifteen lights being assumed equal to the installation), but its use is now to be extended to all contract customers having five or more lights. To make these extensions over 4000 Wright demand indicators will be installed. A most interesting feature of the change to central station men is that with the extension of the Wright demand system, the Boston Edison Company will put into effect a scale of rates which it is expected will completely do away with the inconvenience and expense of figuring out what rate a customer is entitled to. This new scale of rates is designed automatically to give to each customer a rate bearing as nearly as possible a definite ratio to the cost of supplying him.

Principles of Electrical Apparatus

THE SYNCHRONOUS MOTOR.

If an ordinary alternating-current dynamo be driven at normal speed by some outside source of motion (such as a belt from a motor or a running line-shaft), with its field separately excited by direct current, and then connected to an alternating-

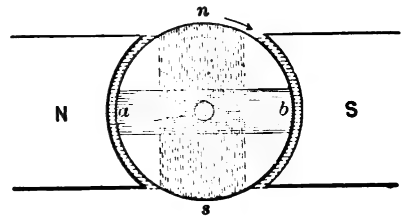

FIG. 1.

current circuit at some instant when its impulse of e.m.f. coincides exactly with that of the circuit, the mechanical connection with the source of motion may be removed and the machine will continue running, being now driven as a motor by current from the circuit. Such a machine is a synchronous motor. This type of motor is like a direct-current motor in one respect, and only one; namely, its construction is, fundamentally, exactly like that of the dynamo that generates the sort of current on

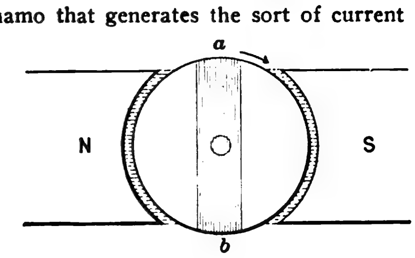

FIG. 2.

which it (the motor) is designed to operate.

Synchronous motors run at precisely the same rate of speed as that of the alternator supplying the circuit on which they run, if the number of magnet poles is the same; hence their name "synchronous." If the poles differ, then the relation between the speeds of the motor and the generator is given by the simple equation

$$P\,S = p\,s \quad\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

in which *P* represents the number of poles on the generator; *S*, its speed; *p*, the number of poles on the motor, and *s*, its speed.

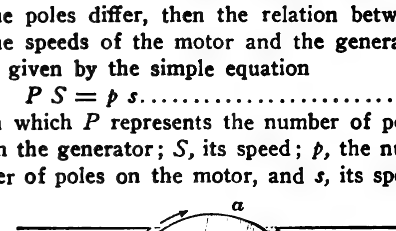

FIG. 3.

The formula is obviously transposable four ways, according to which of the four values one wishes to determine. If *S* and *s* be expressed in revolutions per minute, the frequency, *f*, of the current supplied by any alternating-current generator is equivalent to $P\,S \div 120$, and the relation between the speed of a synchronous motor and the fre-

quency of the current that drives it is expressed by the equation

$$120 f = p\, s \ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

from which obviously follow the formulæ

$$\frac{120 f}{p} = s, \quad \text{and} \quad \frac{120 f}{s} = p.$$

The truth of the foregoing statements may be demonstrated by elementary diagrams, such as Figs. 1 to 7. Here, for

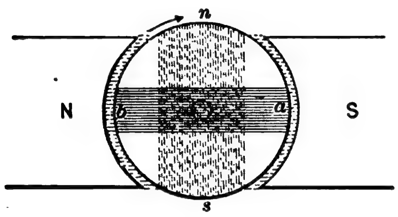

FIG. 4.

the sake of simplicity, a bipolar field magnet and single-coil armature are shown. Suppose the armature to be driven by a belt at such a rate that the armature makes precisely one revolution while the current wave of the supply circuit passes through precisely one cycle; then, if the armature be properly connected to the circuit, it will occupy the position in Fig. 1 when the supply current is at its maximum (neglecting for the present the counter e.m.f., inductance, etc., of the armature), as indicated by the Roman numeral, I, on the current wave, Fig. 7. The armature connections having been properly made, the supply current will induce poles at the periphery of the armature core, as indicated by the letters *n* and

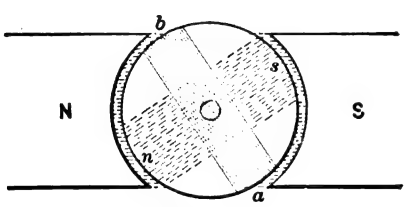

FIG. 5.

s, so that there will be a pull between the field-magnet poles and the armature core tending to assist the rotation of the latter. When the armature core has passed through one-quarter of a revolution, and reached the position shown in Fig. 2, the current will have passed through one-quarter of its cycle and reached zero, as indicated by the numeral II in Fig. 7.

In this position the armature will not have any magnetic poles, but an instant later, when the coil has passed the vertical position, as indicated in Fig. 3, the current will have begun to rise in the opposite direction, as indicated by the numeral III in Fig. 7, producing reversed poles on the armature periphery and resulting in a repulsion between the armature core and the field-magnet poles which renews the rotatory effort in the same direction as before. When the armature reaches the position shown in Fig. 4, having made exactly half a revolution, the current will have attained its maximum direction again, which series of changes is continued so long as the armature revolves at the rate of one revolution per cycle of current. It is evident that under these conditions the armature does not need to be driven by any external source, as the magnetic torque between it and the field poles will cause it to continue to revolve.

Should the speed of the armature be either higher or lower than the frequency of the supply current, the angular or tangential torque between the field-magnet poles and the armature core will be alternately favorable and unfavorable to the direction of rotation. For example, if the armature in passing from the position shown in Fig. 4 should be driven at a rate of speed lower than the frequency of the supply current, so that by the time it reaches, let us say, the position shown in Fig. 5, the supply current will have passed zero and reversed, as indicated by the numeral V in Fig. 7, then poles will be induced in the armature core as indicated in Fig. 5, and the torque between the magnet poles and the armature

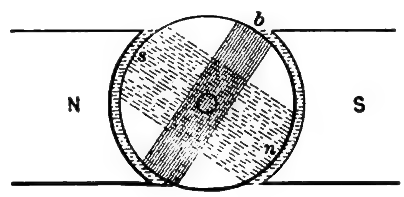

FIG. 6.

will be opposed to its direction of rotation. Again, if the speed of the armature should be more rapid than the rate of current reversals to such an extent that it would be driven from the position in Fig. 4 to that in Fig. 6 before the current had reached zero, as indicated by the numeral VI in Fig. 7 the polarity of the armature will again be such that the field magnetism tends to pull it in the opposite direction. It is evident, therefore, that in order to maintain continuous torque in the same direction between the armature and field-magnet poles, the armature speed must be kept precisely in step with the current reversals. So long as the load on the armature is within its torque ability, it will

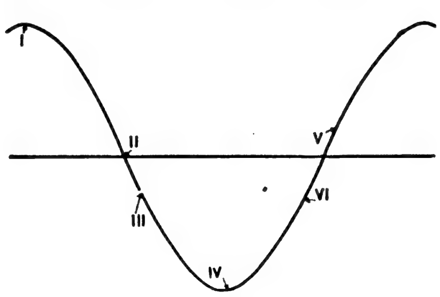

FIG. 7.

maintain synchronous speed, but the moment the drag due to the load exceeds that exerted between the magnet poles and the armature, its speed will be reduced, it will drop out of "step" with the supply current, and come to a standstill.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Care of Storage Batteries.

With reference to the discussion on storage batteries in your recent issues, and more particularly to the communication from Mr. Hartwell, I wish to correct his statement that "as the temperature (of electrolyte) rises 10° F., the specific gravity will *rise* 3°." The converse is the case; that is, as the temperature rises 10°, the specific gravity falls 3°.

Ordinarily in stationary battery practice, the specific gravity should be 1.200 at full charge and at normal temperature, which is 70° F. At other temperatures, allowance should be made accordingly in adjusting the specific gravity. Variations in the temperature materially affect the capacity of a battery. At a temperature between 90° and 100° F. a battery will yield its greatest output. It is not advisable, however, to maintain the temperature at so high a point as this, deterioration of the plates being then more rapid. At such a temperature, the internal resistance and the required maximum charging voltage are lower than at normal temperature (70° F.). On the other hand, the capacity at a very low temperature, say 32° F., is considerably reduced, the internal resistance greater and the required maximum charging voltage greater than at normal temperature. Roughly, the capacity varies 1 per cent with every 2° F. change in temperature between 32° and 90°. Notwithstanding the loss of capacity at lower temperatures, the plates are not injured, and the cells recover their capacity when the temperature is restored to normal.

The charging voltage under normal conditions of temperature, specific gravity and of the active material is governed by the age of the plates and is best determined by the results secured by employing different voltages, as no specific rule can be given to show the maximum voltage to be used in any particular stage of deterioration.

Yonkers, N. Y. W. L. THOMPSON.

A Telephone Circuit Difficulty.

We have a bridged telephone line with ground return, and except in a few cases, all grounds are made by soldering to well pipes. The exceptions are 6-foot and 8-foot ground rods driven into sandy soil. During the latter part of the winter those subscribers having instruments grounded to rods are unable to ring the bells of other parties on the line, although their own bells respond to an incoming signal as well, apparently, as ever. These same generators when grounded to well pipes signal as well as ever, showing that the generators are

not at fault. The ground rod connection seems to be sufficient for conversation, but the generator cannot put enough current to line to ring other bells. In this case there are twenty telephones on the line, hence, neglecting line resistance, 1/20 of the output of any generator will pass through each bell and ground, except the ground of the generator in use. Here 1/20 of the output passes through the bell and 19/20 pass to line to actuate the other 19 bells. Now, the resistance of a conductor is constant at a given temperature, regardless of the current or e.m.f. passing through it. Such being the case, I should like to ask readers of the American Electrician to explain why these ground rods will pass 1/20 of the current put out by other generators, but will not pass the 19/20 that should be sent to line by their own generators.

Osage, Minn. W. H. Shadbolt.

Mr. Weaver's Problem in Switches.

Referring to Mr. Weaver's problem last month, I would suggest the enclosed scheme of connections (Fig. 1). This is not quite up to requirements, if I understand his letter aright, but it is workable. In order to light the lamp, *U*, from downstairs, the switches, *b* and *f*, are closed, and in order to light the lamp, *D*, the switch *d* is closed to the left as the diagram stands. The upstairs switches, *a*, *c* and *e*, work with these switches to give two-station control. In order to put the lamps in series, the switch, *g*, is closed to the right and the switches, *a* and *c*, thrown to whichever side is necessary to open their respective circuits, according to the positions of the switches, *b* and *d*. Then the lamps in series can be extinguished from downstairs by throwing the switches, *b* and *d*.

Ironwood, Mich. Louis J. Gorilla.

Enclosed please find a solution to the problem offered by Mr. B. F. M. Weaver last month (Fig. 2). The switch, *A*, is double-pole, double-throw and the others are all single-pole, double-throw, or they may be single-pole, two-way snap switches.

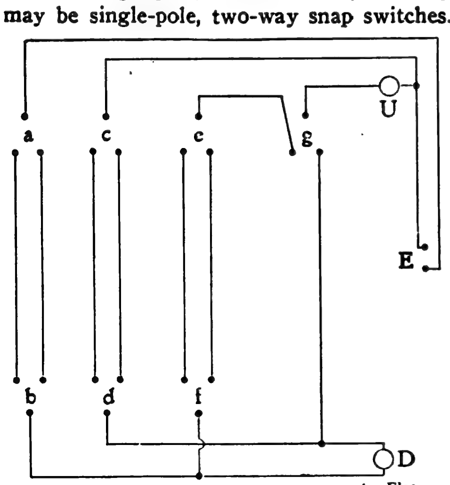

FIG. 1.—MR. GORILLA'S SOLUTION.

With the switch *A* thrown up, the lamps may be controlled separately from either upstairs by means of the switches, *B*, and *E*, or from downstairs by means of the switches *C* and *F*. With the switch *A* thrown downward, the lamps are in series, and may be lighted and extinguished from any one of the four single-pole switches.

Wilkinsburg, Pa. F. W. Harris.

The enclosed diagram (Fig. 3) is submitted as a solution of Mr. Weaver's problem published last month. The switches are all three-point, single-pole, and with the switch *C* closed to the right, the switches *A A'* control the lamp, *D*, on the

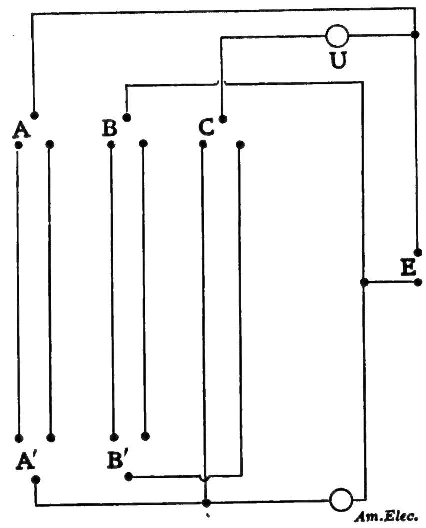

FIG. 3.—MR. LOVELAND'S SOLUTION.

ordinary two-station plan, while the switches *B B'* control the lamp *U* in the same manner. The switch *C* when closed to the left puts the two lamps in series, provided the circuit between the switches *A* and *A'* is open, which can be accomplished, of course, by throwing *A* one way or the other, according to the position of *A'*.

Philadelphia, Pa. Wm. A. Loveland.

[Mr. Loveland's solution fails in the one requirement that the lamps when in series shall be controllable from either upstairs or downstairs.—Editor.]

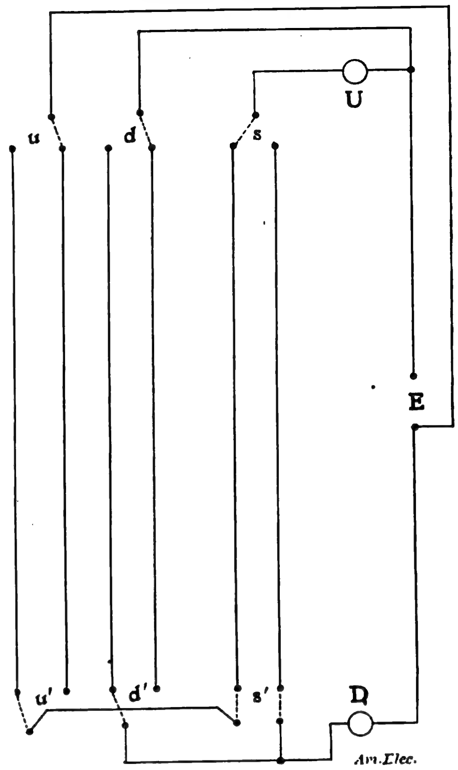

FIG. 4.—MR. MALCOLM'S SOLUTION.

The accompanying diagram (Fig. 4) is offered as one method of accomplishing the results described by Mr. B. F. M. Weaver last month, and a little more; it gives complete control from both stations. With the switches set as in the diagram the lamps are extinguished. Throwing either *u* or *u'*

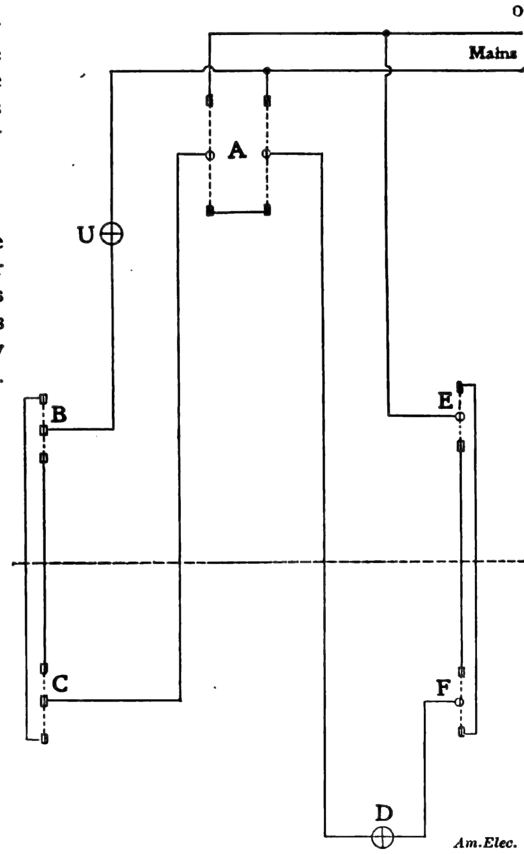

FIG. 2.—MR. HARRIS' SOLUTION.

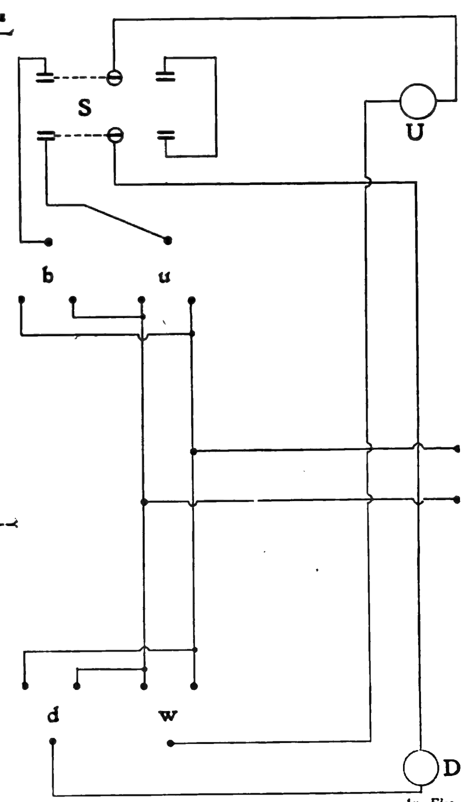

FIG. 5.—MR. MERRILL'S SOLUTION.

will light the lamp *U*, after which throwing either of them will extinguish it. The same is true of the switches *d* and *d'* and the lamp *D*. Again with the switches as in the diagram, throwing either *s* or *s'* will put the two lamps in series on the line, and the next throw of either of these switches will extinguish them. Therefore, the lamps can be controlled separately, in parallel or in series from either station, regardless of the positions of the switches at the other station.

Brooklyn, N. Y. GEO. W. MALCOLM.

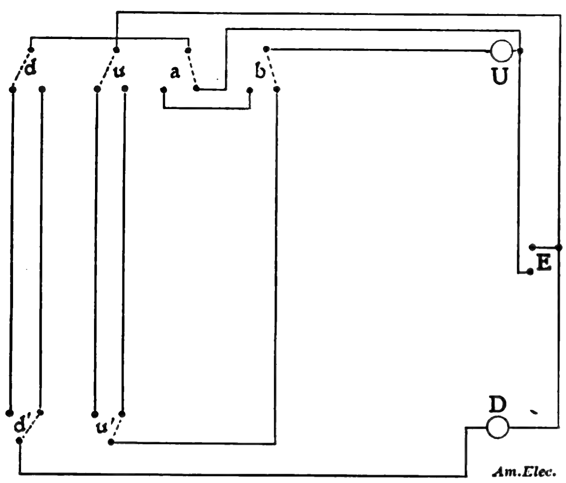

FIG. 7.—MR. WEAVER'S SOLUTION.

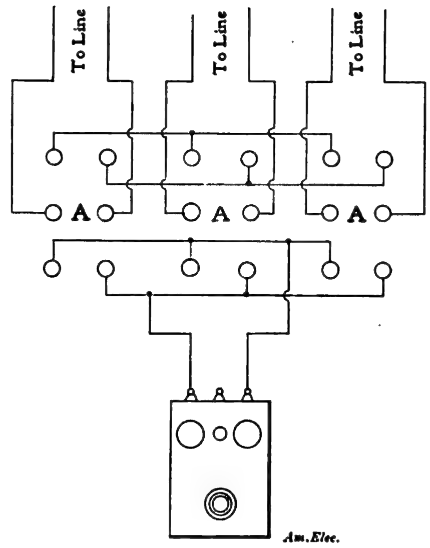

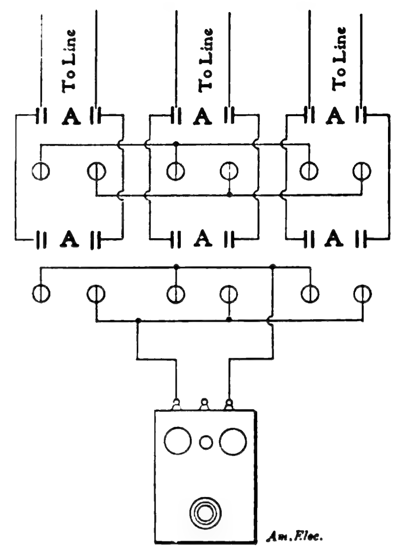

FIG. 1.—MR. EDDY'S SOLUTIONS TO MR. BRODE'S PROBLEM.—FIG. 2.

I enclose herewith a diagram of switch connections (Fig. 5) which is offered as a solution of Mr. Weaver's problem published in your last issue. The double-pole, double-throw switch, *S*, puts the lamps either in parallel or in series, and the three-point switches, *u* and *w*, control the lamp *U* while the switches *d* and *b* similarly control the lamp *D*, when the switch *S* is in the parallel position (that shown in the sketch). When the switch *S* is thrown to the right, putting the lamps in series, they can be lighted and extinguished by any one of the four three-point switches.

Wilmington, Del. WM. MERRILL.

The enclosed diagram (Fig. 6) shows a possible arrangement for solving Mr. Weaver's problem in switch connections published last month. Five three-point and two electrolier (double-pole reversing) switches are employed. With this arrangement either or both of the lamps may be lighted and at full candle-power and extinguished from either station, independently of the switches at the other station, and the lamps may be put in series from the upstairs station; when in series they can be turned on and off at either station.

Syracuse, N. Y. N. D. RAND.

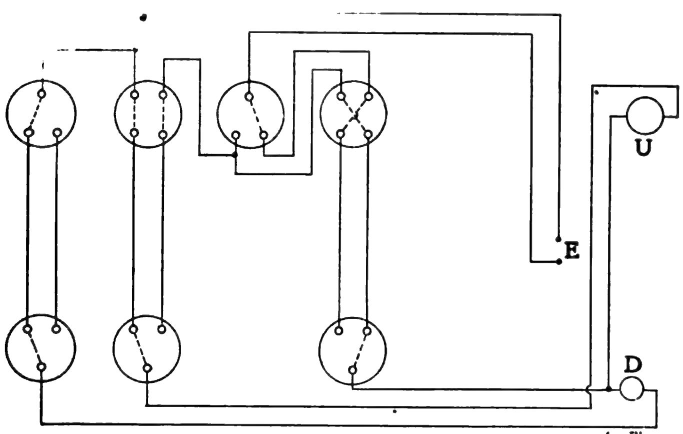

FIG. 6.—MR RAND'S SOLUTION.

[Fig. 7 shows Mr. Weaver's own solution of his problem, and is almost self-explanatory. The switches are all three-point, single-pole. As they are shown in the diagram, the lamps are out, and may be lighted and extinguished separately by means of the switches *d*, *d'*, *u* and *u'*; throwing the switches *a* and *b* to the left puts the lamps under the control of the switches *d* and *d'* in series. It is quite obvious that the switches *a* and *b* could be displaced by a double-pole, two-way switch.—EDITOR.]

Mr. Brode's Problem in Telephone Connections.

I submit herewith two diagrams (Figs. 1 and 2) as solutions of Mr. Brode's problem in telephone connections which was published in this department last month. In Fig. 1 three double-pole, double-throw knife switches are used, each switch being arranged to connect one of the lines to a pair of cross-connecting bus-wires when thrown upward or to the local telephone instrument when thrown downward. One of the switches would always be down and the other two up, to fulfill the conditions of the problem. One disadvantage of this arrangement is that a person at the station where this is located cannot listen in on either of the two wires which are connected together without disconnecting the two. In order to remedy this, the second solution is offered. Here six double-pole, single-throw switches are used; the upper three are used to cross-connect and the lower three, one at a time, to connect the local instrument with any one of the three lines. The extension call bells are not shown; they are, of course, connected one to each line above the switches in both solutions.

So. SHAFTSBURY, VT. J. G. EDDY.

[Exactly the same solution as Fig. 1 has been received from Ernest Prosch, Coytesville, N. J.—EDITOR.]

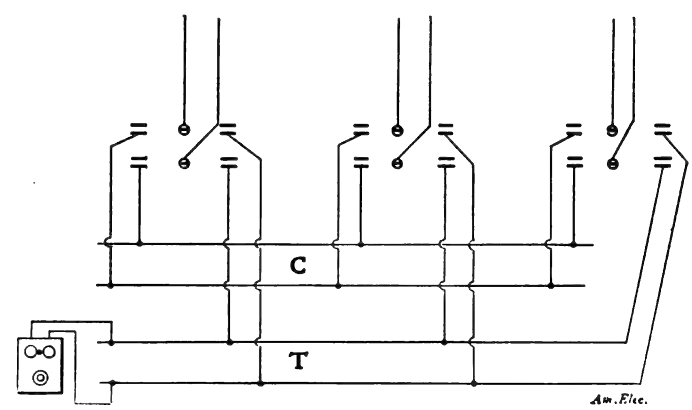

FIG. 3.—MR. HOLMES' SOLUTION.

I enclose herewith a solution of Mr. Brode's problem in telephone connections (Fig. 3): Each of the three lines is connected to the pivots of a double-pole, double-throw knife switch, and these switches connect their respective lines either to a pair of cross-connecting busses, *C*, or to the local instrument busses, *T*.

Brooklyn, N. Y. C. E. HOLMES.

The accompanying diagram (Fig. 4) fulfills the requirements contained in Mr.

Brode's letter last month. The switch, *A*, connects line No. 2 to either line No. 1

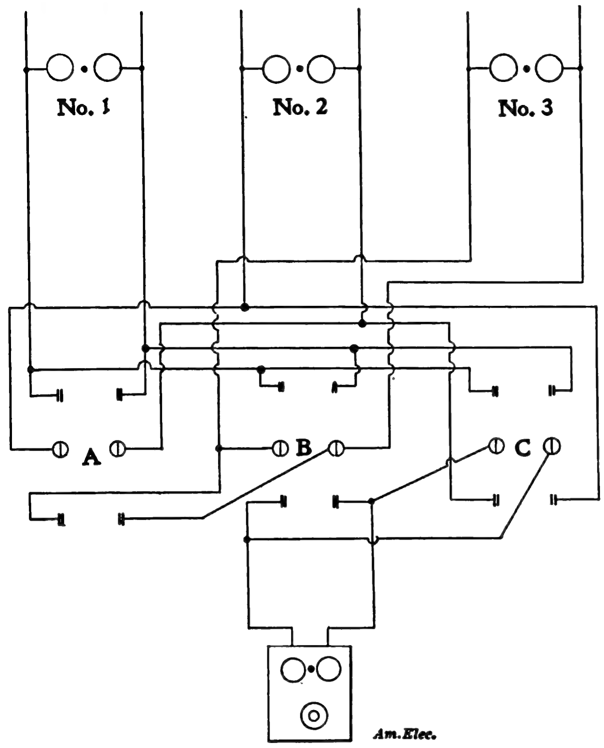

FIG. 4.—MR. LOVELAND'S SOLUTION.

or line No. 3; the switch, *B*, connects line No. 3 either to line No. 1 or to the local instrument; the switch, *C*, connects the local instrument either to line No. 1 or to line No. 2. By following out the combinations it will be found that any two lines may be connected together and the local instrument connected to the remaining line; also that no matter which two lines are connected, the local instrument can be disconnected from the remaining line and cut in on the two connected lines to "listen in" so as to prevent liability to cut the lines in the middle of a conversation.

Philadelphia, Pa. W. A. Loveland.

The enclosed sketch (Fig. 5) shows one way to solve Mr. Brode's problem in telephone connections. Three double-throw, double-pole knife switches are used to control the line connections; the lower jaws of these are cross-connected, so that closing

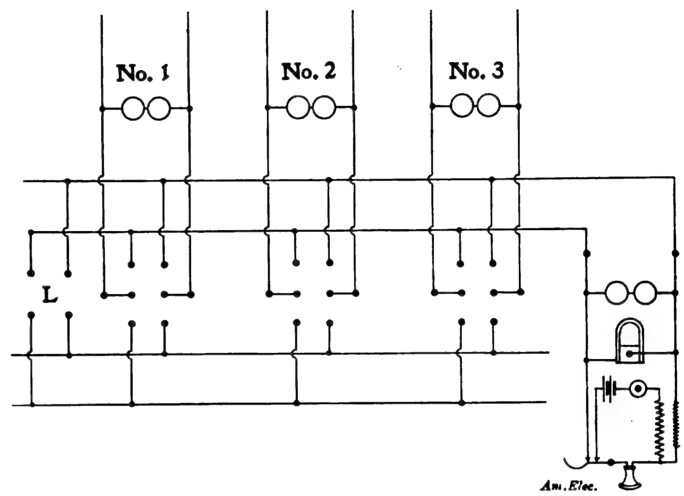

FIG. 5.—MR. WILSON'S SOLUTION.

any two switches downward connects the two corresponding lines. The upper jaws are also cross-connected, and are connected in addition to the local telephone instrument, so that closing any switch upward puts the instrument on the corresponding line. In order to "listen in" on the two connected lines without breaking the connection, the single-throw switch, *L*, is closed. All switches should be left open when the lines are idle.

Carlisle, Ind. M. C. Wilson.

Mr. Wolf's Problem in Motor Connections.

The accompanying sketch is an ideal way of controlling a motor from two points, as required by Mr. Wolf's problem last month. The motor starter is of the automatic electrically-operated type, the motor circuit being closed and the armature resistance cut out by a solenoid excited from the work circuit. The wires, *c*, *c'*, carry the current for the solenoid, and may, therefore, be No. 12 or 14 gauge. The wire, *c'*, is always connected to one side or the other of the supply mains (which is allowed with this type of apparatus) by the double-throw, single-pole switch, *S'*, and the wire *c* is similarly connected by the switch, *S*; the two switches thus give two-station control to the starting solenoid. The No. 8 wires carry the motor current.

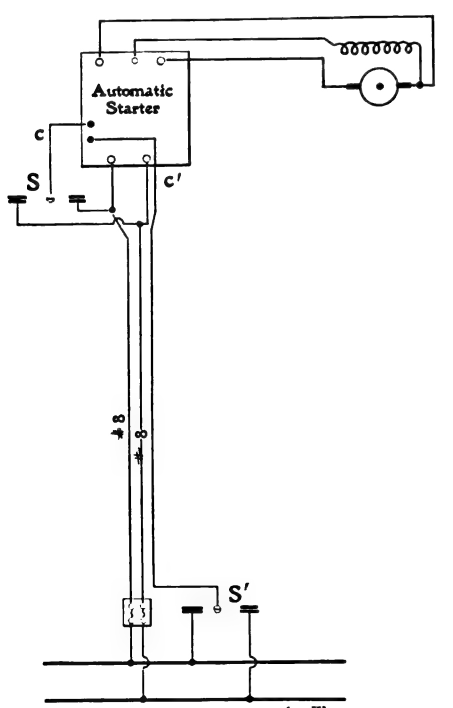

FIG. 1.—MR. BARBER'S SOLUTION.

North Adams, Mass. W. J. Barber.

Mr. Wolf's problem in motor connections is easiest solved by putting an automatic mot--starter on the upper floor with the motor and controlling the starter by means of the familiar two-station control used for incandescent lamps. Fig. 2 illustrates how this may be done. It also shows that a

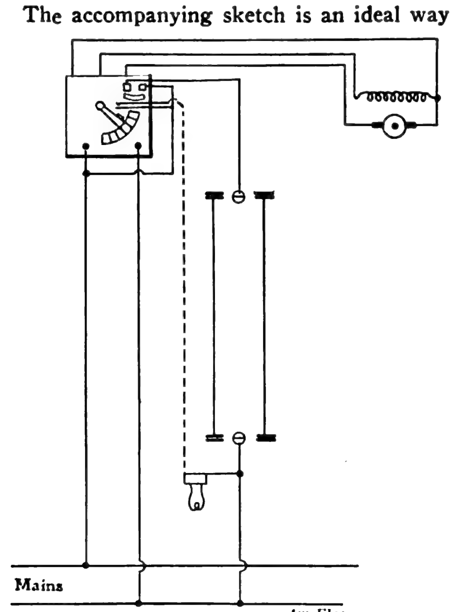

FIG. 2.—MR. LOVELAND'S SOLUTION.

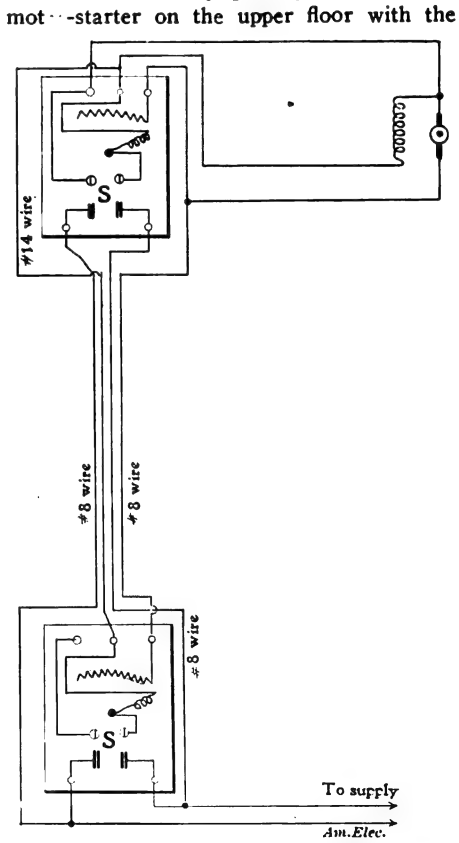

FIG. 3.—MR. MALCOLM'S SOLUTION.

pilot lamp could be connected up to auxiliary contacts on the motor-starter, these contacts to be closed by the starter arm. The dotted lines show this connection.

Philadelphia, Pa. W. A. Loveland.

The sketch herewith (Fig. 3) shows the simplest method of solving Mr. Wolf's problem with ordinary starting boxes. The diagram is so obvious that no explanation is necessary beyond saying that the swinging arms of the starting boxes have been omitted, the pivots merely being indicated by the black dots in the centers of the boxes. This arrangement makes each starting box and its main switch, *S*, entirely independent of the other one when the motor is at standstill; of course, the motor cannot be shut down from one station after it has been started from the other one; if it should be desired to do this, an automatic starter could be employed and controlled on the ordinary two-station plan by three-point switches and No. 14 wires. Geo. W. Malcolm.

Brooklyn, N. Y.

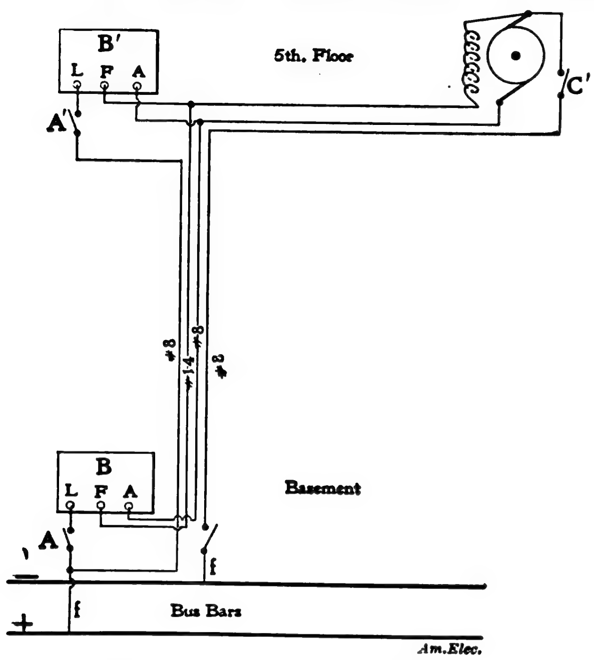

FIG. 4.—MR. SWEETNAM'S SOLUTION.

Referring to Mr. Wolf's problem, I would suggest the arrangement shown in the enclosed sketch (Fig. 4). The starting boxes are of the ordinary no-voltage release type. The motor may be started from either point by closing the switch, *A* or *A'*, and manipulating the corresponding starting box. If it be desired to shut it down from one point after it has been started from the other one, the switch, *C* or *C'*, would be opened long enough to let the starting box release, and then closed again. Fuses must be inserted at *f, f*.

A. H. Sweetnam.

Lafayette, Ind.

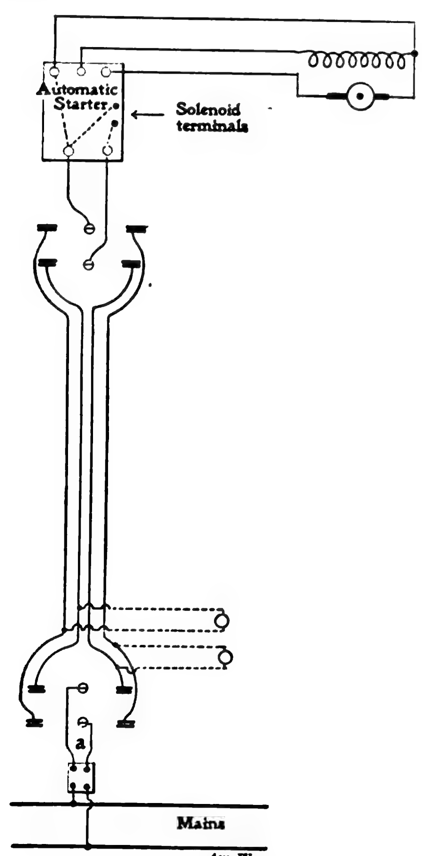

FIG. 5.—MR. TEEL'S SOLUTION.

I would like to offer the following solution of Mr. Wolf's problem: An automatic starter is installed upstairs with the motor and controlled by means of two double-pole, double-throw switches. As both poles of these switches carry the full motor current, all four of the wires in the conduit must be No. 8. The solenoid of the automatic starter is connected across the main circuit upstairs, as indicated in the sketch (Fig. 5). I would suggest that an ammeter be inserted in the circuit just beyond the fuse block, at *a*, to indicate whether or not the motor is working.

Aquashicola, Pa. John W. Teel.

[A less expensive method of indicating the condition of the upstairs circuit would be to connect up two pilot lamps as indicated by the dotted lines which we have added to Mr. Teel's excellent diagram.—Editor.]

Mr. Bannister's Dynamo Trouble.

Referring to Mr. Bannister's dynamo trouble, I would suggest that when the armature leads were short-circuited no current was supplied to the field magnet coils, and the field magnetism died out; the armature current then magnetized the field magnet poles in the contrary direction, and when the machine was next started up the leads to the field winding had to be reversed to correspond to the reversed field polarity.

Brooklyn, N. Y. Herbert B. Brand.

Mr. J. T. Bannister's dynamo trouble, mentioned in this department last month, was probably due to self-induction of the line or some apparatus on the line which caused a discharge through the field winding when the armature leads were short-circuited, and thereby reversed the residual field magnetism. It will be noticed when an armature is short-circuited that the flashing at the brushes is intermittent, as though a surging, or alternate charging and discharging were occurring.

Philadelphia, Pa. W. A. Loveland.

[The reversal of the residual field magnetism of Mr. Bannister's dynamo had nothing to do with the necessity for reversing the field winding connections. A shunt-wound dynamo will operate with either polarity without changing the leads or any connections whatever; if it happens to "pick up" with the right-hand terminal positive, for example, it will operate with that polarity, and if it happens to "pick up" with the left-hand terminal positive, it will operate equally well that way, with no change in the field or armature connections. The accompanying elementary sketches will show this to be true. Assuming that current passing through the field winding in the direction of the arrow in Fig. 1 will make the left-hand brush positive, the machine will operate that way; if it should get its residual field reversed and pick up in the opposite direction, the right-hand brush would be positive, as shown in Fig. 2, and current would be sent through the field winding in the opposite direction to the first case, as indicated by the arrow, thus maintaining the reversed polarity at the brushes.

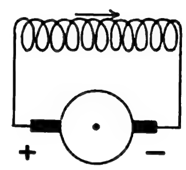

FIG. 1.

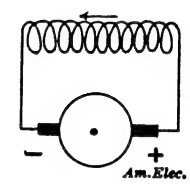

FIG. 2.

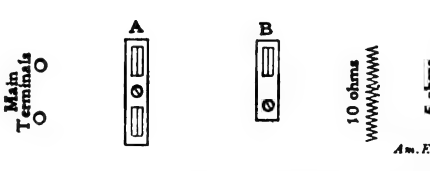
What probably happened was that in re-assembling the machine after repairing the armature damage either the brush leads or the leads to the field winding were accidentally reversed, so that the machine would not excite itself until they had been reversed back to their original relation.—Editor.]

Switch and Resistance Connections.

I should like to submit the following problem in connecting resistances: Connect the two resistances in series and obtain 15 ohms, or in multiple and get 3.33 ohms, or connect one resistance at a time so as to get 10 ohms or 5 ohms; the switches are one single-pole double-throw and one single-pole single-throw.



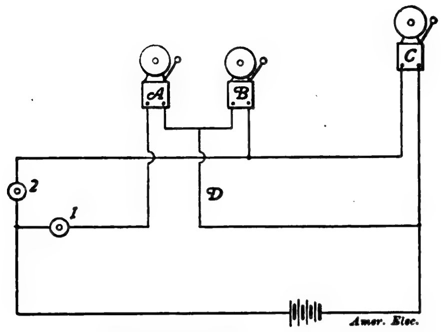
PROBLEM IN SWITCH AND RESISTANCE CONNECTIONS.

H. B. Brown.

Schenectady, N. Y.

Peculiar Bell Action.

I enclose a diagram of a case in bell work, which, although it is not a problem, might prove so to the man who encountered it in his work. The curious part of it is that the corroding of a wire causes all the bells in the house to ring in series. The bells, *A* and *B*, are together in the



PECULIAR BELL ACTION.

kitchen, while *C* is upstairs. Of course the back-door button, marked 1, should ring *A*, while the front-door button, 2, should ring *B* and *C* in multiple. The battery wire, however, has corroded off at *D*, with the result that the button 1 will ring all the bells in series.

F. B. MORTON.

Boston, Mass.

Mr. Westervelt's Insulation Test.

Find enclosed my solution to Mr. Westervelt's problem in the February issue. Apparently the difficulty is due to the grounded neutral and the exciting circuit of the wattmeter, which is between the cut-out *A* and the panel *B*. When the voltmeter is connected across the negative side of the line, and the exciting circuit of the meter connects with the positive side, there will be a

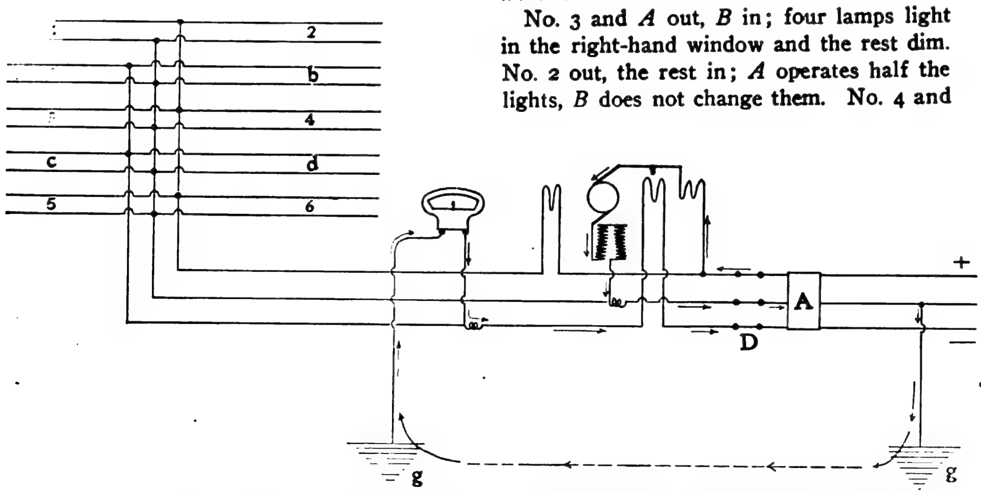


FIG. 1.—MR CARPENTER'S SOLUTION OF MR. WESTERVELT'S PROBLEM.

path through the exciting circuit of the meter and neutral to ground, to the voltmeter, then to the negative line. If the voltmeter and shunt circuit resistance could be determined the exact cause could be computed. By disconnecting the shunt of the wattmeter and renewing the test, the matter will be detected. A proof of the above is shown by having the same voltmeter reading when six of the branches are tested separately and together. This is accounted for by having six branches on the side that cause the voltmeter and wattmeter to be connected as above; the other branches will not indicate because the connection will be of such a nature as to prevent the "voltmeter-wattmeter" complication. I have experienced precisely the same trouble with a grounded neutral system.

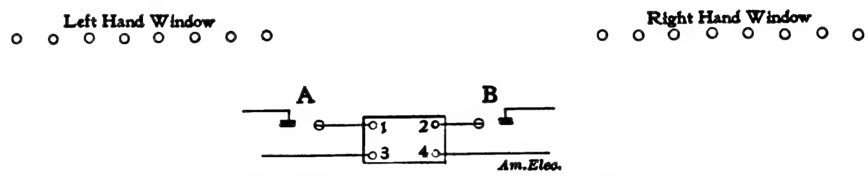
FRANK B. CARPENTER.

Birmingham, Ala.

Faulty Circuit Connections.

The following problem in misconnections may be of interest to some of your readers: Two windows, right and left-hand, are each lighted by eight lamps fed from the two ends of a double-branch plug cut-out, fused with plugs 1, 2, 3, 4, and controlled by two single-pole switches, *A* and *B*, so that normally every lamp in the two windows is turned on by each switch. The wiring was apparently in accordance with ordinary methods, but the wires from the cut-out to the windows were concealed. Nothing unusual was noticed until plug No. 4 burned out, when it was found that with switch *A* turned off and *B* on, every other light in the left-hand window burned bright, the other four in the left-hand window and all in the right-hand window burned dim, and on testing the various possibilities of switches and cut-outs, the following facts were determined:

No. 3 and *A* out, *B* in; four lamps light in the right-hand window and the rest dim. No. 2 out, the rest in; *A* operates half the lights, *B* does not change them. No. 4 and *B* out, *A* in; four lights in left-hand window lighted, the rest dim, but the bright ones are opposite from the first case. No. 3 and *B* out, *A* in; four lights in the right-hand window lighted, the rest dim, but the bright ones are opposite from the second case.



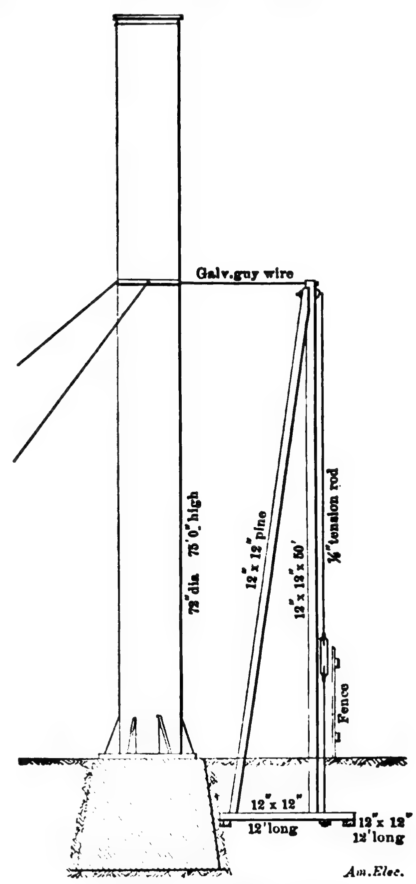
PROBLEM IN FAULTY CIRCUIT CONNECTIONS.

JOSEPH HARDWICK.

New London, Conn.

Supporting a Steel Stack.

We had erected a new battery of boilers and were about to set up the new 75-foot stack, when we found that our neighbor strenuously objected to a guy wire passing over his lot. It was pointed out to him that the guy wire would be placed well overhead, but without avail. A reasonable sum of money was then offered, but our friend would not accept thinking we would eventually be obliged to purchase his lot. While we would have bought his lot for future enlargement of the plant, still we did not want to have the guy wire affect the price, so we resorted to the arrangement shown in the accompanying sketch. We embedded two 12-foot timbers in the ground and then bolted another timber at right angles to the other two. From this latter piece we set up two 50-foot timbers coming together at the top and spread about six feet at the bottom. We ran our much-desired galvanized guy wire to the top of this structure and then put a ⅞-inch tension rod from the top to the underground horizontal timber.



SUPPORTING A STEEL STACK.

The tension was then adjusted by a turnbuckle placed at a convenient height above the ground. The arrangement was satisfactory in every way.

JOHN D. ADAMS.

Phœnix, Ariz.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

Can a 133-cycle fan motor be changed to run on 60 cycles? W. G. B.

Not with any degree of satisfaction.

Is the Tirrell regulator adapted as well for controlling a compound-wound exciter as for a shunt-wound exciter? G. D. E.

No; because it cannot control the compounding of the field magnetism.

Is it practicable to refill dry batteries? F. W. M.

No; but they may be renewed to a considerable extent by passing current through them backwards just as you would charge a storage battery.

What other metals will behave the same as lead when placed in sulphuric acid? (2) How are lead-covered cables drawn into underground conduits? B. S.

None. (2) By means of a winch and wire rope attached to the starting end of the cable.

Is it possible for a condenser after being charged and disconnected from the charging circuit to have a higher e.m.f. across its terminals than the e.m.f. of the charging circuit? C. M. G.

No; when a condenser is charged its potential is brought up equal to that of the charging circuit.

What would be the result if the ammeters of three compound-wound generators were connected in the series mains instead of the armature main as described in Mr. Gassman's article in the February number? E. T. W.

The meters might not indicate the actual current output of the machines, but would indicate the division of current between the series windings of the different machines.

Will synchronizing lamps, or any other form of synchronizer, indicate phase differences between two machines while the two are connected in parallel? A. C. K.

No. Moreover, there cannot be any serious difference in phase between two machines connected in parallel without throwing one of them out of step and causing the circuit-breakers or fuses to blow.

In which lead from a direct-current dynamo should the circuit-breaker be connected? T. H.

With a shunt-wound machine it makes no difference; with a compound-wound dynamo, the circuit-breaker, as well as the ammeter, must be in the lead coming from the dynamo brush terminal (as distinguished from the lead coming from the free terminal of the series winding).

Can two series-wound direct-current machines of the same output and capacity be operated in series to supply double the number of lamps? (2) What are the proper connections for two single-phase transformers on a three-phase circuit? (3) How should two single-phase meters be connected to a three-phase circuit? F. D. E.

Yes. (2) Connect them up as though three transformers had been connected up in delta and one of them removed. (3) With the current coils inserted in two of the circuit leads and the potential terminals of both meters connected to the third lead.

For what can dry cells be used after they have become polarized? (2) How can a 4-volt miniature lamp best be lighted from a 110-volt direct-current circuit? A. R. T.

The best use to which they can be put is to serve as a counter e.m.f. in cases where dead resistance would ordinarily be used. See Mr. Hanchett's article in the May, 1904, number. (2) By connecting it in series with a dead resistance sufficient to take up 106 volts. The number of ohms necessary to do this may be ascertained by dividing 106 by the current which the lamp requires.

Which of the two methods shown in the accompanying diagrams (Figs. 1 and 2) is the best for connecting two lamps for two-station control? L. F. A.

Fig. 2 is preferable for the reason that each lamp is independent of the condition

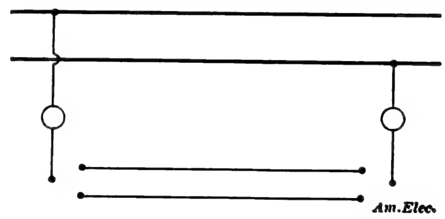


FIG. 1.

of the other one. Fig. 1 is just as good so long as the lamp sockets and filaments are in good condition, but if one of the sockets should accidentally be turned off or disabled or one of the filaments be broken it

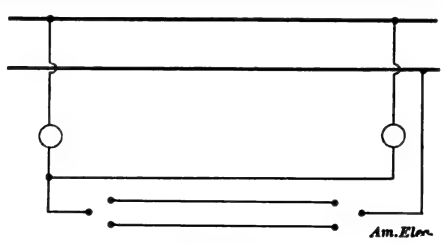

FIG. 2.

would, of course, prevent the other lamp from lighting. Moreover, in Fig. 1 the lamps must be of one-half the circuit voltage.

What is the proper timing for the igniter of a gasoline engine running at 200 r.p.m.? (2) How far from the end of the stroke should the exhaust valve begin to open? A. B. C.

With an engine running at so slow a speed the igniter would probably give the best results if set to act just as the crank reaches the dead center. (2) Your question cannot be answered without a complete knowledge of the engine and indicator cards taken from it; the point of the stroke at which the exhaust valve opens varies with different engine designs.

What size of wire and how many turns should be used for the coil of the magnetic vane voltmeter described in the December, 1903, number to make the instrument give full scale deflection at 15 volts? (2) Would the metal used in ferrotype photographic plates be suitable for the vanes? (3) Could a shunt be used with the meter for higher voltages? H. I. M.

Fifteen hundred turns of No. 22 wire. (2) Yes. (3) Shunts are used with ammeters, not with voltmeters. You can adapt the instrument for higher voltages by using dead resistance in series with it.

How should the three-pole armature of a battery motor be wound and connected up? (2) What size of wire should be used on the armature? (3) Is double cotton-covered wire preferable to single silk-covered? (4) How many feet of No. 32 German silver wire are required to get a resistance of one ohm? H. A. L.

Wind a coil on each pole, making all three coils exactly alike; connect the three inner terminals of the coils together and the three outer terminals to the segments of a three-part commutator. (2) This depends upon the size of the motor; ordinarily about No. 18. (3) Double cotton covering is preferable where space is not a vital consideration. (4) German silver wire is made in several grades. The grade known as 18 per cent alloy has a resistance of about ½ ohm per foot.

A ½-h.p. four-pole single-phase induction motor wound for 60 cycles runs at only 1400 r.p.m. and is sluggish in starting. The fields have been rewound and only two starting coils used. What is the probable trouble? (2) Can a compound-wound generator be tested for its compounding ability and a saturation curve plotted without giving it a full load? (3) Why have the Manhattan rotary converters six collector rings when they are supplied from three-phase transformers? (4) Can a rotary converter be used for electroplating, or is a motor-generator more efficient? W. H. S.

The use of two starting instead of four coils accounts for the sluggish starting of the machine, but not for the enormous slip in its speed. It is either heavily overloaded or the new winding has been connected up wrong. (2) Not satisfactorily. (3) Because the secondaries of the transformers are connected up to give six phases and the converters are built correspondingly. (4) Yes, provided wide voltage regulation is not required. The motor-generator is preferable because the voltage can be varied through a wide range; its efficiency is lower than that of a converter.

How can the internal resistance of a primary battery cell be measured? (2) Does its voltage decrease as the current output increases? (3) Does the internal resistance vary under different conditions? (4) How can the internal resistance of a battery of primary cells be made equal to the external circuit resistance, at the same time keeping the battery voltage within the ordinary limits for such work? H. M. W.

Measure the e.m.f. on open circuit with a high-resistance voltmeter; then connect the cell to a known resistance in series with an ammeter of known resistance; divide the open-circuit voltage by the ammeter reading and subtract from the result the resistance of the external circuit (including that of the ammeter, of course); the remaider will be the resistance of the battery cell. (2) The available voltage decreases because of the drop in the cell itself; the actual voltage of the cell decreases with use by reason of the gradual polarization of the cell, but this is not true of the gravity type of cell for closed circuit working. (3) It varies with changes in the electrolyte; not otherwise. (4) By designing the external circuit properly. Ordinarily there is no liability to get an impractical battery e.m.f. in trying to obtain the relation you mention; moreover, in such special cases as might tend to produce this result, it will be more economical to sacrifice the "equal resistances" idea than to pay for the battery necessary to apply it.

COMPARATIVE HEAT CONDUCTION AND RADIATION OF INSULATING VARNISHES.

BY JOHN C. DOLPH.

The necessity of providing liquid insulation for cotton covering of copper wire in coils has long been recognized, but whether the use of varnishes or compounds is really necessary, other than as a means of protection against moisture, especially in low-voltage work, has been open to discussion.

Early in 1903 the writer was impressed with the idea that the life of the coils could be greatly lengthened by increasing the natural tendency of insulating varnishes to dissipate heat either by radiation or conduction, or both. All experience up to this time had clearly demonstrated that ordinary insulating varnish was a very poor conductor of heat, and it was taken for granted that any improvement in this direction would carry with it the introduction into the varnish of material which would have a tendency to lower to the danger point the dielectric strength of the varnish coating.

With these conditions in mind the writer began a series of experiments with varnishes and compounds with the idea of treating them in such a manner as to produce a compound which would constitute an improvement over anything then in use in its ability to conduct and dissipate by radiation the heat generated in the insulation of the windings of high-potential, alternating-current apparatus. These experiments clearly demonstrated that there existed a great difference between the temperature of coils insulated with the varnish specially treated for heat radiation and conduction and the ordinary insulating varnish. To determine accurately this difference, the writer took up the matter with Dr. Sharp, of the Electrical Testing Laboratories. The following method to determine the combined heat radiation and conduction of various varnishes was followed:

A number of tin cans were provided, on the outside of each of which a layer of cloth was tightly fastened, the cloth then being painted with three coats of the varnish to be tested. Dry steam having 10° C. of superheat was then passed through each can in turn and the amount of steam condensed per minute was determined. At the same time a thermopile set up at a given distance from the can was used to determine the relative radiating powers of the surfaces which were afterwards expressed in the terms of galvanometer deflections. An uncovered tin can, as well as a can covered with soot, was provided for the purpose of comparison. These tests established beyond any question the marked superiority in point of combined heat radiation and conduction of the specially treated varnishes over the ordinary insulating varnishes. During these tests a peculiar condition developed as regards one of the clear oleo-resinous base varnishes under test. While this varnish was naturally a poor radiator of heat, owing to the nature of its surface, it proved to have gotten rid of a larger proportion of heat than any of the other varnishes tested with the exception of that treated specially for heat radiation and conduction. Inasmuch as this oleo-resinous bas varnish possessed good insulating properties, it occurred to the writer that varnishes of this description, in view of this important characteristic, were the ones which would eventually give the best results, provided they could be so treated as to develop the necessary heat radiation and conduction without the sacrifice of their high insulating properties.

It was then determined to ascertain, by electrical means, the relative combined heat conducting and radiating properties of various oleo-resinous and hydrocarbon base varnishes. There were provided eleven spools, approximately six inches in length and three inches in diameter. These spools were wound with No. 18 double cotton-covered wire, 18 layers and 108 turns to the layer, making a total of 1944 turns. In these coils were wound thermometric coils, the outside of No. 38 silk-covered wire with two turns per space, making a total of 214 turns; a middle thermometric coil of No. 40 silk-covered wire, two turns per space, with a total of 214 turns, and an inner thermometric coil of No. 40 silk-covered wire, three turns per space, making a total of 321 turns. These coils were wound on a split form so that they could be handled without the addition of insulation other than that provided by the covering of the wire and the varnish used on the coil. The wire in all cases was run through

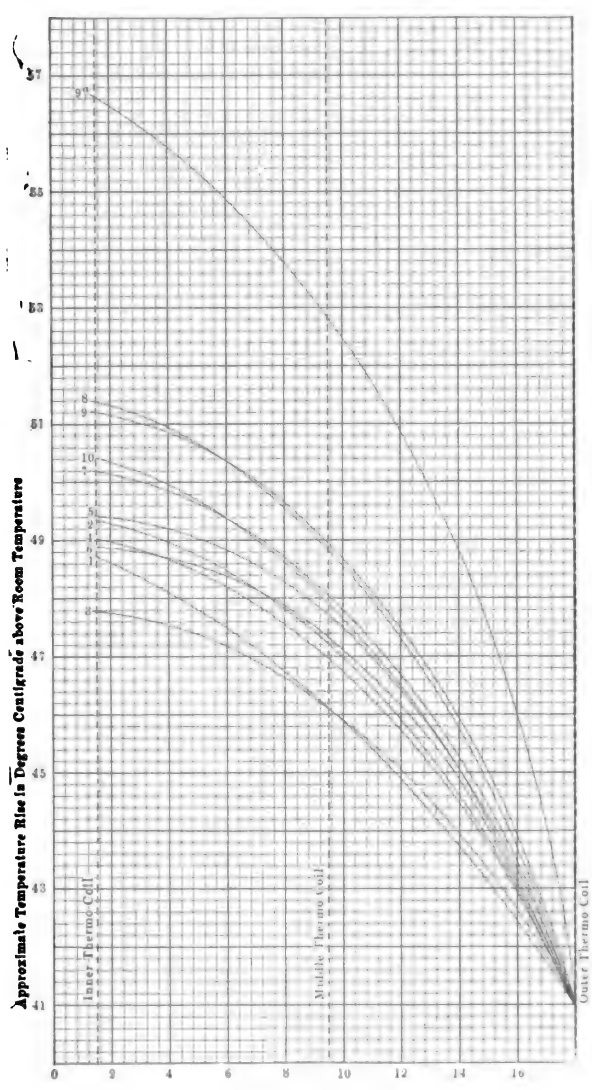

FIG. 1.—TEMPERATURE RISE DURING TEST NO. 1.

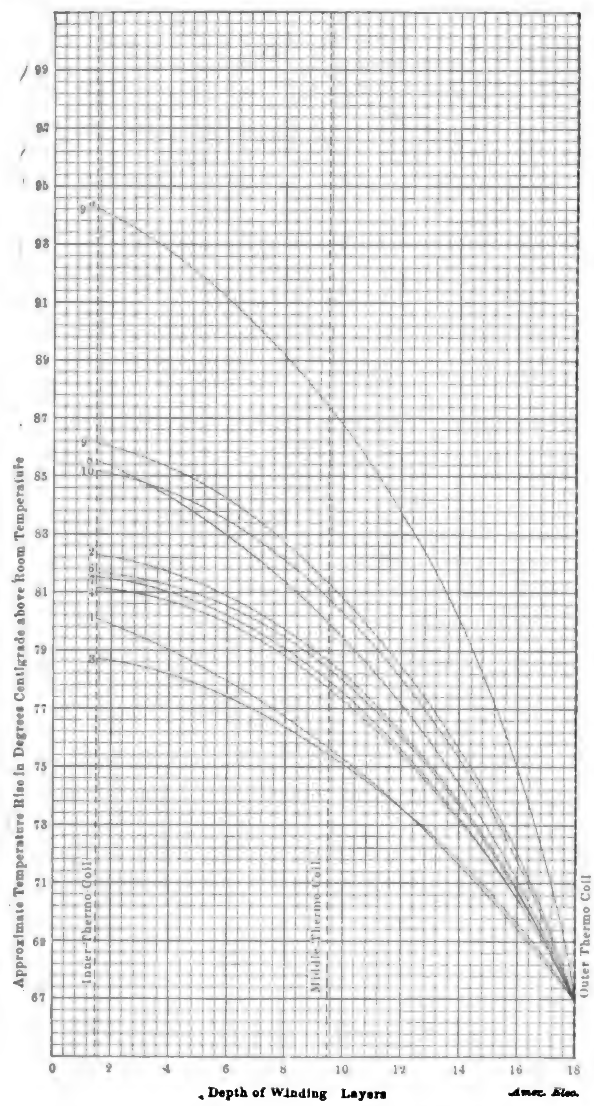

FIG. 2.—TEMPERATURE RISE DURING TEST NO. 2.

the varnish to be tested as the wire was wound on the coil. The inner thermometric coil was wound on the first layer of No. 18 wire, as of course it was not possible to wind it on the outside of the first layer.

The spools were numbered from 1 to 10, inclusive, and were treated with varnishes and compounds as follows:

No. 1 Spool—Clear, quick baking, dipping varnish of oil and gum base variety.
No. 2 Spool—Clear, baking, dipping varnish, of an oil and gum base variety.
No. 3 Spool—Heat radiating varnish, brown, dipping, baking, of a combined oleo-resinous variety, specially treated for heat radiation and conduction.
No. 4 Spool—Black, dipping varnish of an oil and hydro-carbon base variety.
No. 5 Spool—Black, solid compound of bituminous variety, liquefied under heat and used only in connection with vacuum impregnation apparatus.
No. 6 Spool—Black, brushing varnish of a combined oil and hydro-carbon base, treated for heat radiation and conduction.
No. 7 Spool—Clear, baking, dipping varnish of an oleo-resinous variety.
No. 8 Spool—Black, air drying and baking, dipping varnish of one of the hydro-carbon group.
No. 9 Spool—Black, air drying and baking, dipping varnish of a second of the hydro-carbon group.
No. 9a Spool—Untreated coil of No. 18 double cotton covered copper wire, wound up dry.
No. 10 Spool—Gray, brushing, baking varnish of an oleo-resinous variety, treated for heat radiation and conduction.

The varnishes on spools Nos. 1, 2, 3, 4 and 6 were manufactured by the Standard Varnish Works. The varnishes used on other spools were those supplied in the market in the United States and Europe for insulating purposes.

It was proposed to obtain the information desired by two similar methods.

1. Heating the spools by passing a constant current through them and getting the temperature at the inner, the outer and middle surfaces by means of the fine wire thermometric coils. (The spool showing the greatest difference between extremes would be the one from which the heat escaped most slowly.)

2. Heating the coils by passing a known constant current through them, and measuring the average rise in temperature of the spool by its increase in resistance. Under the circumstances the spool that became the hottest would be the poorest dissipator of heat.

A number of tests were made, but in the first series the current used was not sufficient to cause a temperature rise in the spools above 60° C. In the last series of tests made, as shown by the curves, sufficient current was used to carry the temperature up to, and in some cases above, that which is met with in the commercial operation of dynamos and motors in service.

The temperature rises were computed from a temperature coefficient of copper assumed to be .00383. This is based on the latest value at 0° C., approved by the A. I. E. E. (viz.: .0042), and corresponds to 23° C., the general average room temperature throughout the above tests. However, the exact value of the coefficient is unimportant, as only comparative results could be expected.

In the last test referred to the spools were all connected in series and set on end on a table in a circle, with about twelve inches of air space between spools. The air spaces in he middle of the coils were corked up at the tops, forcing nearly all of the heat to escape from the outer surfaces. The two ends of each thermometric coil were then so arranged that they could be readily connected to a Wheatstone bridge. Arrangements were provided for getting the potential across each spool rapidly at stated intervals. The observations were made as follows: First, the resistance of each thermometric coil was measured on a Wheatstone bridge; second, a known current was sent through the main coils and the fall of potential through each was noted every fifteen minutes for about three and a half hours, or until the drop became constant; third, when the temperature became constant, as indicated by the constancy of the drop, the resistance of the thermometric coils was again measured. (Precautions were taken to have the external radiation conditions the same for all spools and to avoid air drafts.)

SUMMARY OF TESTS NOS. 1, 2, 3 AND 4.

	Test No. 1		Test No. 2		Test No. 3.		Test No. 4	
Spool No.	Ratio.	Relative. order.	Ratio.	Relative. order.	Ratio.	Relative. order.	Ratio.	Relative. order.
1	.494	2	.466	2	.484	2	.465	8
2	.532	5	.545	6	.651	7	.643	6
3	.437	1	.419	1	.479	1	.456	1
4	.510	3	.506	3	.530	3	.522	3
6	.513	4	.527	5	.530	4	.530	4
7	.590	6	.520	4	.568	5	.538	5
8	.661	9	.581	7	.670	8	.663	7
9	.654	8	.685	9	.688	9	.759	9
9a	1.000	10	1.000	10	1.000	10	1.000	10
10	.603	7	.653	8	.643	6	.739	8

The table herewith gives a summary of the four tests and the curves show the temperature rise throughout the eleven treated coils and the comparative rise in the untreated coil, No. 9a.

On the diagram it will be observed that the curves have been shifted up or down, as required, to bring the temperatures at the outside to the same point for all spools. This procedure spreads the curves out more and renders the difference between them more noticeable to the eye.

It should be borne in mind that the above

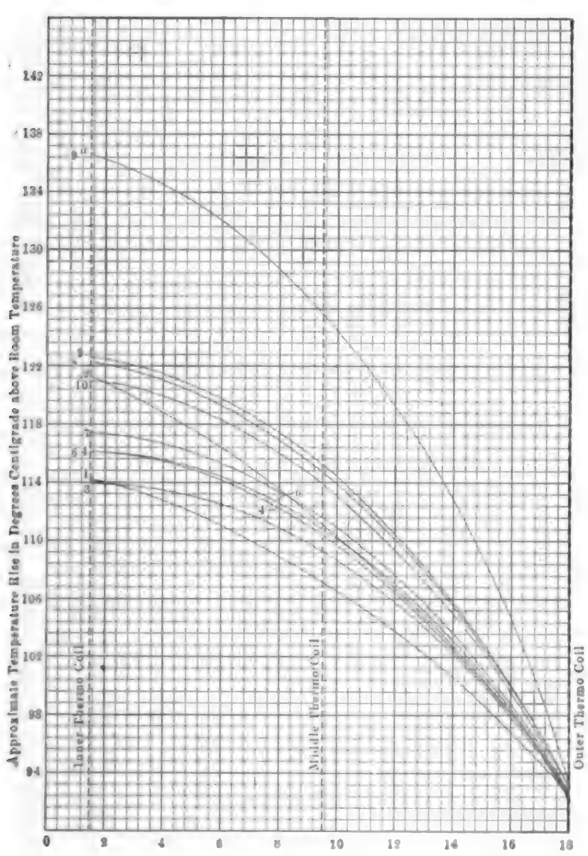

FIG. 3.—TEMPERATURE RISE DURING TEST NO. 3.

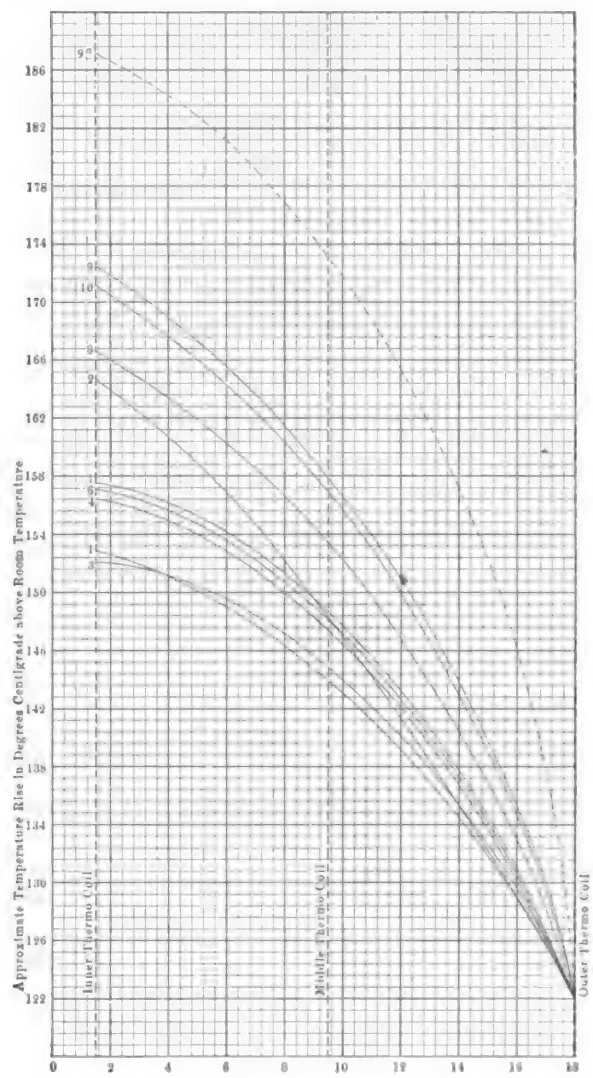

FIG. 4.—TEMPERATURE RISE DURING TEST NO. 4.

results are affected by both the heat radiating ana heat conducting properties of the compounds, hence the relative order obtained cannot be said to be due to either alone, but to the combined effects of both.

The spool No. 3, while showing among the best, is treated with a clear dipping baking varnish, which has high power of penetration, and whose insulating properties have not been affected by its special treatment for heat radiation and conduction, as will be observed by the table below, which gives the puncture test of the varnishes used on the spools in the test for heat radiation and conduction.

Spool No. 1	798	volts per mil.
Spool No. 2	783	" " "
Spool No. 3	826	" " "
Spool No. 4	703	" " "
Spool No. 5	No test made.	
Spool No. 6	917	volts per mil.
Spool No. 7	811	" " "
Spool No. 8	765	" " "
Spool No. 9	890	" " "
Spool No. 10	83	" " "

The results of the tests for heat radiation and conduction show conclusively the superiority in this respect of coils treated with insulating varni-hes or compounds over the untreated coil wound up dry.

THE KOERTING FOUR-CYCLE GAS ENGINE.

The demand for a satisfactory power to run automobiles and launches has been instrumental in accelerating the development not only of the small type of internal combustion engines used for this purpose, but also the larger types employed for the commercial generation of power. From the rapid development of these large power units it may be predicted that these engines will soon become as popular in this country as they now are in Europe.

In the Koerting four-cycle engine, shown in Fig. 3, the inspiration and compression of combustible gases and the expulsion of the burned gases are effected directly by motion of the main motor piston itself.

By reference to the sectional engravings it will be seen that when the engine piston has advanced about half way on its expansion stroke, the gas, which ignites at the instant the crank passes center, delivers its energy to the crankshaft. On the return stroke the exhaust valve is opened and the burned gases expelled. As the engine again passes center the exhaust valve is closed and the admission valve is opened, allowing a fresh charge to be drawn in. The gas and air are supplied to the mixing valve through separate regulating valves; the one being on the gas main and the other on the air line, which terminates at the hollow frame of the engine, through which the air supply is taken. This cools the metallic parts, the hollow frame also acting as a silencer for the inflowing air.

When the full charge of gas and air has been drawn into the cylinder the admission valve closes and the charge thus trapped is compressed by the returning piston to a pressure and temperature which have been found by practice to give the best economy.

As will be seen by reference to the sectional views, the cylinder and the combus-

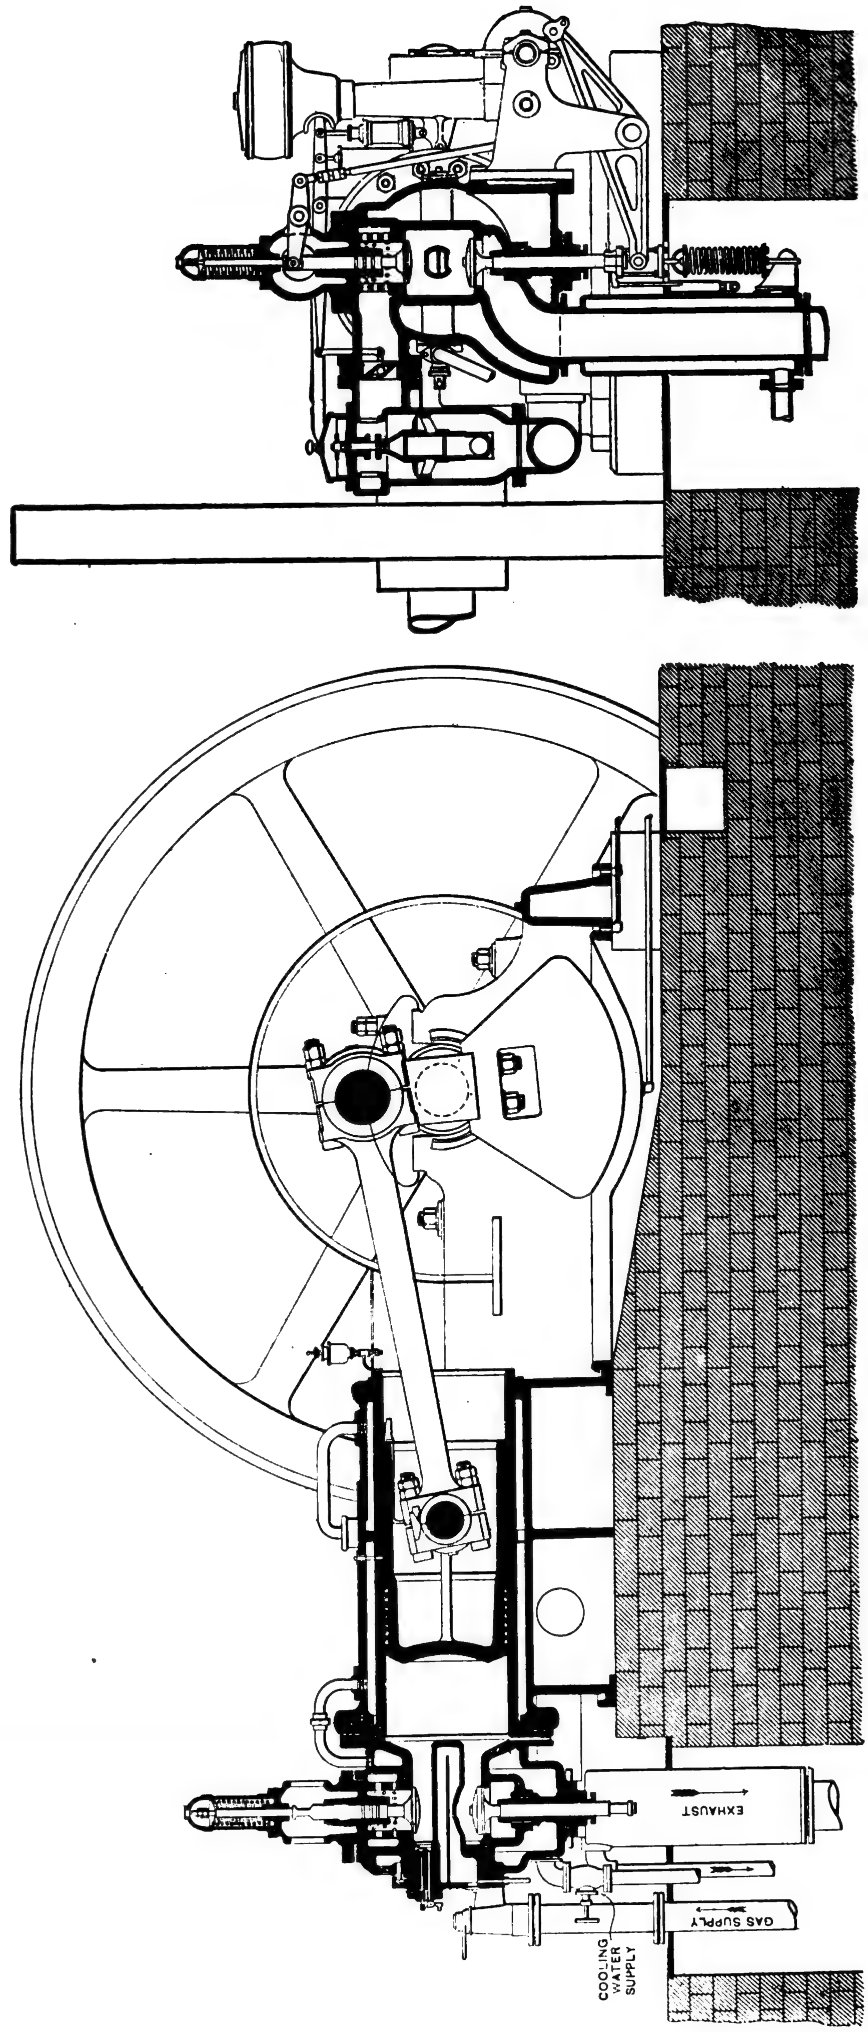

FIG. 1.—LONGITUDINAL AND TRANSVERSE SECTION OF KOERTING FOUR-STROKE CYCLE GAS ENGINE—FIG. 2.

tion chamber are water-jacketed. High economy in gas engine practice depends on the degree of compression that can be carried or the amount of gas which can be made to occupy the clearance spaces of the cylinder and combustion chamber at the beginning of stroke. On the other hand, since the temperature increases quite rapidly with the pressure, unless cooling methods are provided the degree of compression at which the richer gases will ignite spontaneously will soon be reached.

Obviously, any heat carried away by the cooling water is lost, so that no more cooling should be done than is absolutely necessary to admit of the desired compression. This engine is said to owe much of its economy to the design of these water-cooling chambers.

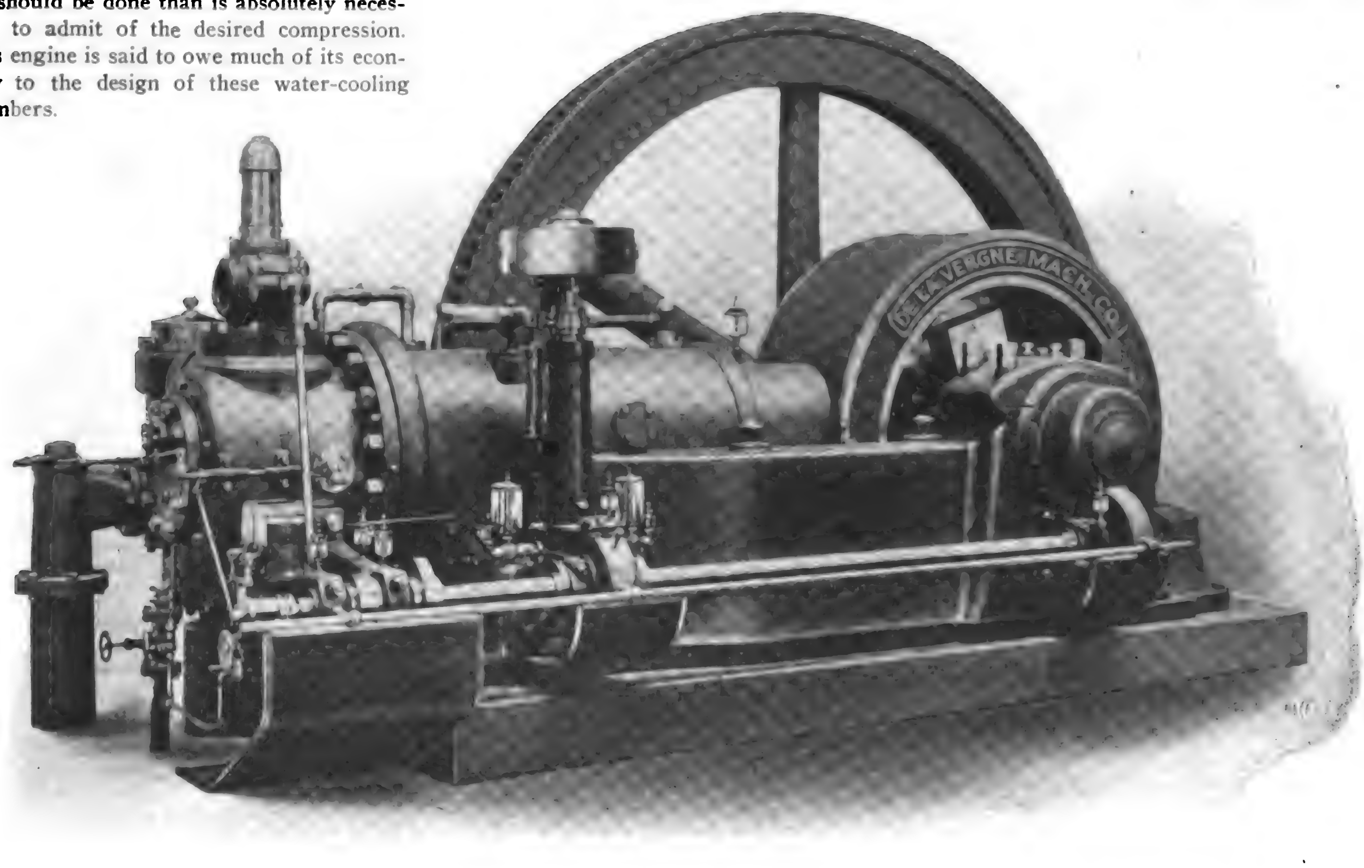

FIG. 3.—KOERTING FOUR-STROKE CYCLE GAS ENGINE.

Rich gases ignite at a much lower temperature than the "leaner" ones. For the same cooling effect compression of the former gas cannot be carried as high as that of the latter and for the same degree of compression a greater cooling effect is necessary in the former case than in the latter.

Ignition is effected in both the four and the two-cycle engine by means of magnetos, the leads from which terminate in an igniting plug inserted in the cylinder head. These plugs when pushed home seat on an asbestos gasket and are secured by four studs. The stationary rod which forms one terminal of the magneto is insulated from the metallic portion of the plug by two tapered porcelain plugs. The movable rod, which forms the other terminal of the magneto, is free to turn in its bushings and is actuated by the valve mechanism. The mechanism which drives the magneto is so arranged that the armature is first turned slowly through about one-third of a revolution against a spring. At the instant the charge is to be ignited the magneto lever is disengaged and the spring gives the magneto armature a quick jerk back to its original position, sending an electrical impulse through the igniting plug terminals, which break contact at the proper instant, thus igniting the charge. In the larger size engines two igniters are operated in unison and the large charges being ignited at two points insure uniform combustion.

One of the main features of design to which this engine is claimed to owe its superiority over many other types is the perfect symmetry of cylinder construction. It will be noted that the cylinder barrel has no lugs or projections of any kind cast on its surface, a fact which insures perfect rectilinear expansion under all conditions of temperature. The cylinder barrel is held in position by the main cylinder stud bolts, which also secure the combustion chamber and head to the main frame. The main engine frame is of unusually solid design, completely surrounding the motor cylinder barrel and supporting it at both ends and in the middle in such a way as to form a concentric water jacket. Since the motor cylinder barrel is secured longitudinally only at the head it is perfectly free to expand and contract with every change in temperature.

The water coming from the jackets is used in cooling the exhaust gas either by means of a water jacket on the exhaust pipe or by direct injection into the exhaust pipe. The cooling of the gas having the effect of reducing its volume, tends to silence the exhaust and reduce the back pressure on the machine.

Tests made on the Koerting four-cycle engine with gas of about 500 B.T.U. per cu. ft. gave thermal efficiencies per brake horse-power of 28.22 per cent., 29.05 per cent., 29.23 per cent. and 31.96 per cent.

The popularity of the engine in Europe is shown by the fact that in the past four years over four thousand have been put into operation. These engines are built in the United States by the De La Vergne Machine Company, of New York, which company has the exclusive right to manufacture and sell these engines, as well as the Koerting two-cycle, double-acting engine. This company has erected for the Lackawanna Steel Company, of Buffalo, the largest single gas engine installation in the world. This plant when completed will aggregate 40,000 horse-power, 32,000 of which will be occupied in operating blowing engines and 8,000 in driving direct-connected generators, three of which are 500-kw, 250-volt, direct-current Sprague dynamos and five of which are 500-kw, 440-volt, three-phase, 25-cycle General Electric dynamos.

COPPER LEADING-IN WIRES FOR INCANDESCENT LAMPS.

Ever since the first practical incandescent lamp was made, it has been the fixed conviction of the electrical engineering fraternity that leading-in wires of any metal except platinum were absolutely hopeless, and the industry has gone along on that basis, facing a constantly decreasing supply of platinum which has increased its price something like 100 per cent. If present indications prove accurate, this bugbear has been demolished by an extremely simple expedient which appears to make it thoroughly practical to use copper instead of

platinum for the leading-in conductors; this expedient consists in forming each wire into a circle where it is enclosed in the glass mount, with the entering and emerging straight-line part of the wire joining the circle at diametrically opposite points, as shown in the accompanying illustration. There are no joints, however, the complete conductor being formed from a single piece of wire. The conductor in the circular part is extremely attenuated by the die which forms it into that shape, but since copper

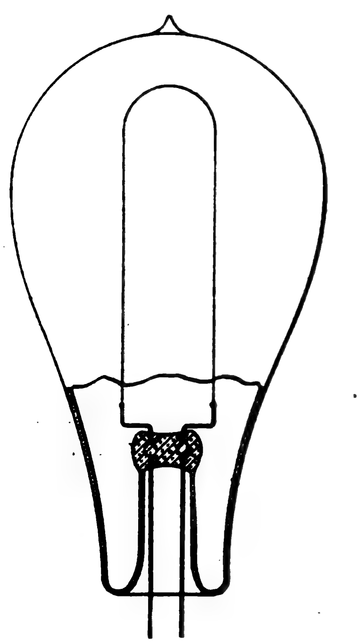

FIG. I.—INCANDESCENT LAMP WITH COPPER LEADING-IN WIRES.

has a much higher conductivity than platinum, the smallest cross-section that can be handled in the course of manufacture without excessive breakage is ample to carry the current for a 32-c.p., 110-volt lamp. Consequently, the same leading-in wires would be used in practice for 32-c.p. and all other lamps of lower candle-power at 110 volts, and for all 220-volt lamps up to 50 candle-power.

This form of leading-in wire was invented by Mr. John H. Guest, who is widely known in electrical circles as one of the pioneers in the electric lighting and railway fields. Mr. Guest was, in fact, one of the very earliest workers in the realm of incandescent lighting, having been a contemporary of Edison, Maxim, Sawyer and the other investigators of the problem in the early eighties. He has taken out a number of patents, some of his lamp patents dating back to 1879 and 1880, and all of which indicate the fertility and originality of the typical inventor and investigator of scientific problems.

Of course, "the proof of the pudding is in the eating of it," and it is rash to make any predictions as to the ultimate fate of a development of this character; its permanent value can be determined only by a time test after the details of manufacture have been perfected and standardized. But it is of interest to note that two lamps equipped with the Guest copper leading-in wires have been burning at full candle-power in this office, all day and every day except Sunday, since March 20.

MURRAY ENGINE FOR HEAVY DUTY.

The Murray Iron Works Company, Burlington, Ia., some time ago brought out a "rolling mill" type of engine designed for high steam pressures and high speeds, and therefore especially well adapted to electric lighting and power service. Fig. 1 illustrates the general form of the bed and guide housing, which are cast in a single piece. The cylinder is, of course, bolted to the rear end of the guide housing, and the latter

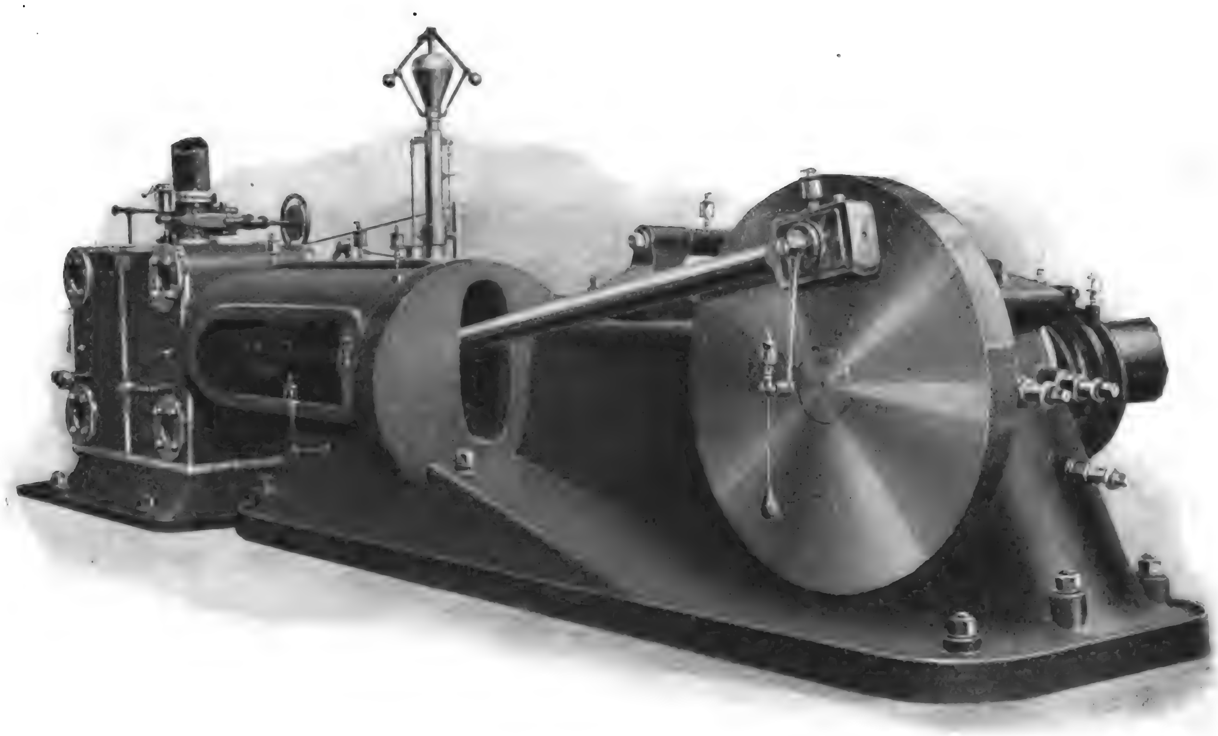

FIG. I.—MURRAY HEAVY DUTY CORLISS ENGINE.

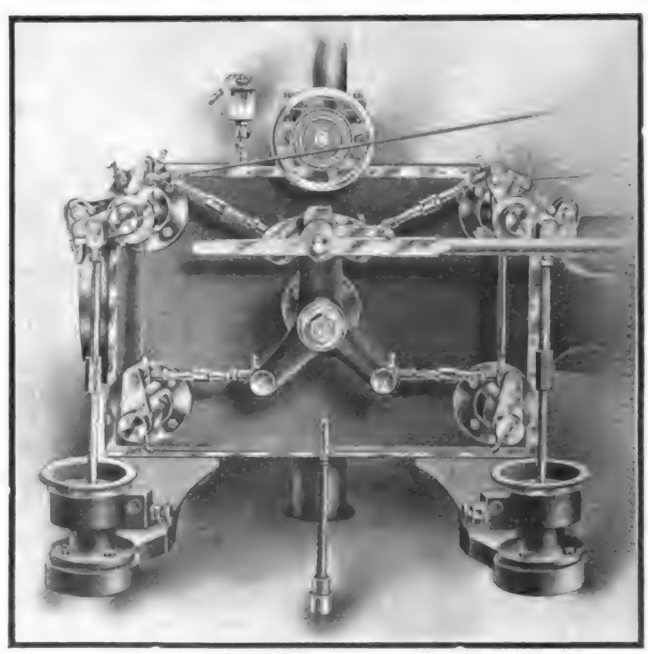

FIG. 3.—VIEW OF VALVE GEAR.

is supported solidly by the bed throughout the whole length of the guides; the advantages of this feature are obvious.

The cylinder is cast with a wide air space between the barrel and the exhaust chest,

so that the temperature of the cylinder barrel is not affected by contact with the low-temperature exhaust steam. This is shown in Fig. 2, which is a longitudinal section

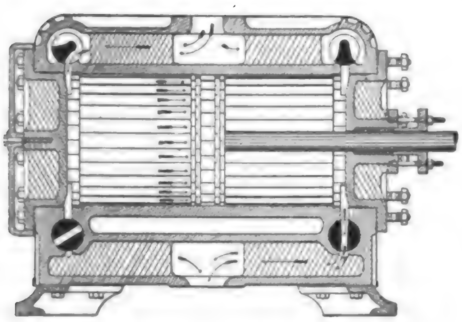

FIG. 2.—SECTIONAL VIEW OF CYLINDER AND STEAM CHEST.

through the cylinder, steam and exhaust chests, valves and valve chambers. This view also shows that the form of valve used differs importantly from the conven-

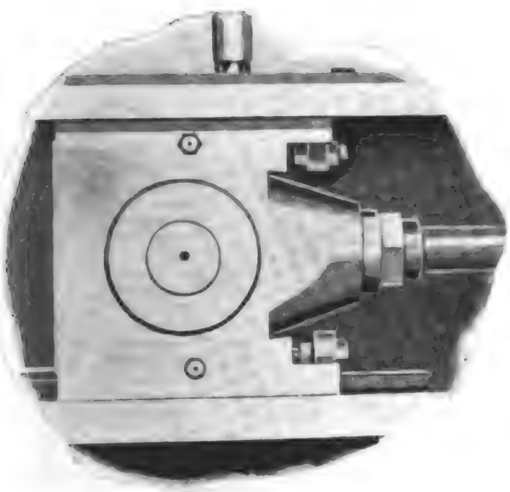

FIG. 5.—CROSS-HEAD.

tional type used by many of the old builders of Corliss engines. The steam valves open away from the incoming steam and are driven by T-head valve spindles, leaving them free to seat themseles accurately. The exhaust valves have through ports instead of being merely cut away on one side, and they are consequently well balanced, the stationary ports in the walls of each valve chamber being diametrically opposite each other.

The cylinder is provided with massive feet, two of which project sufficiently to form seats for the two dash-pots of the steam valve gear, as shown clearly in Fig. 3. The dash-pots are remarkably simple and effective. Fig. 4 shows a sectional elevation of the type used on engines of medium and large sizes. The plunger is of the double diameter type, the smaller part of it serving as a guide and also as the "sucker" to draw the valve arm down. The large part cushions the mechanism on the body of air drawn in the chamber beneath it on the up-

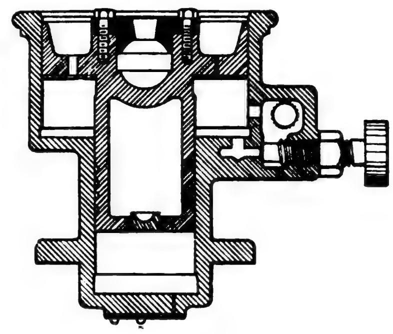

FIG. 4.—DASH-POT.

ward motion; the cushioning is regulated by means of the valve at the right of the illustration. The plunger is attached to the drop rod by means of a ball-and-socket joint so as to allow perfect freedom and self-alignment. The pot is finished all over, and as the seats on the cylinder feet are finished true with the bore of the valve chambers, the dash-pots come true with the valve gear when bolted to their seats.

The valve gear (shown in Fig. 3) and the governor are familiar to all readers of this paper, having been fully described in the general description of American engines published in our June, 1903, number and being in wide use throughout the United States.

The cross-head employed on all Murray engines is illustrated by Figs. 5, 6 and 7, and is a particularly strong feature. It is box-shaped and heavily tapered top and bottom, where it fits the edges of the shoes, the latter being of a sort of channel iron cross-section, as indicated in Fig. 7, and provided with adjusting screws and nuts as shown in Figs. 5 and 6. This construc-

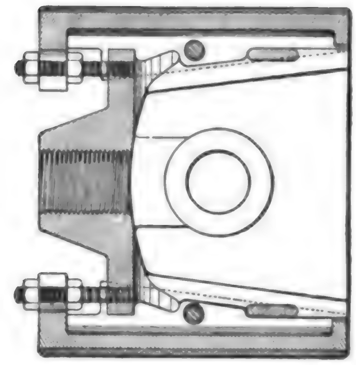

FIG. 6.—CROSS-HEAD.

tion permits the use of a very heavy neck to receive the end of the piston rod, as may be seen by inspection of Fig. 6, which eliminates liability to failure at this point. The rod is screwed into the cross-head, a

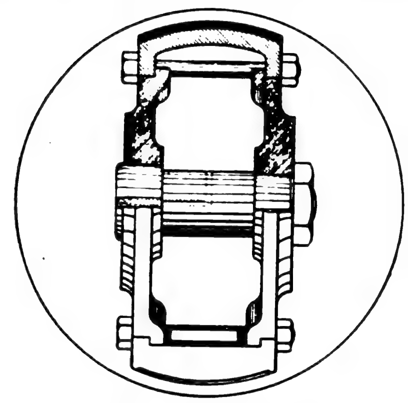

FIG. 7.—CROSS-HEAD.

heavy thread being used which is practically equal in strength to the solid part of the rod. The construction just described also allows the use of a cross-head pin supported at the ends without involving excessive weight or clumsiness of parts. The guides are bored concentric with the cylinder seat, and the cross-head shoes are, of course, turned to fit the guide bore.

For very large high-speed engines, the

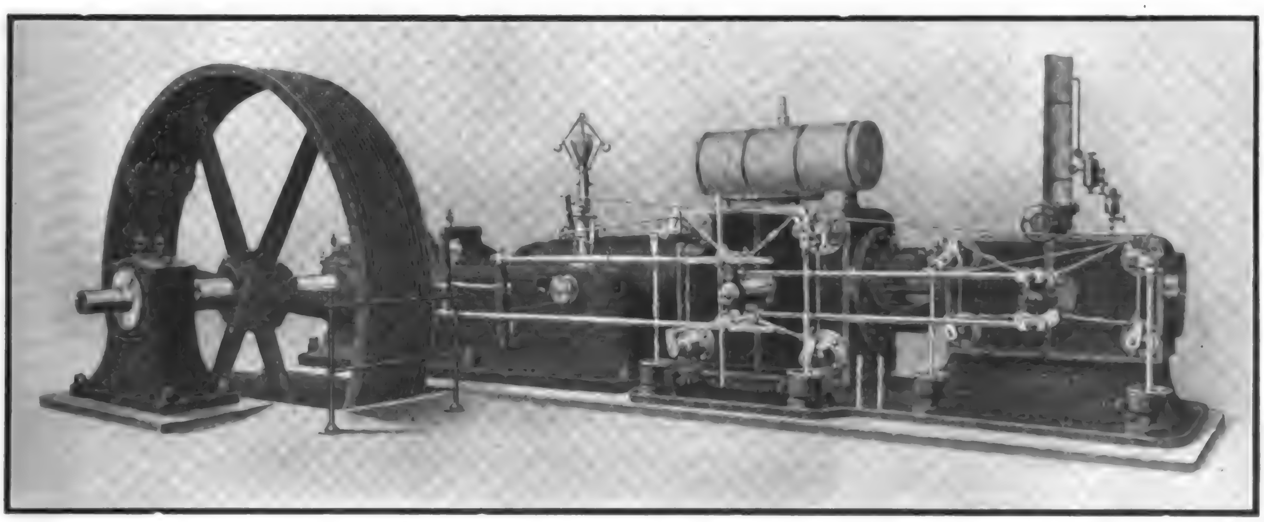

FIG. 10.—MURRAY TANDEM-COMPOUND CORLISS ENGINE.

double-ported valves illustrated in Fig. 8 are used, giving large port openings with small valves and short valve travel. On direct-connected engines, the main bearings are provided with the wedge adjustment shown in Fig. 9, in order to facilitate centering the generator armature in its field magnet. The engraving is self-explanatory.

These engines are built, of course, in cross and tandem compound forms and with either single-eccentric or double-eccentric valve gear, according to the requirements of the purchaser. Fig. 10 illustrates a tandem compound with double-eccentric valve gear and a grooved fly-wheel for rope

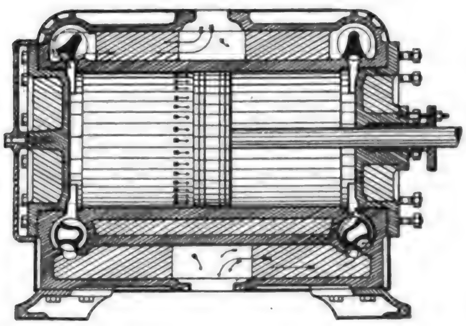

FIG. 8.—SECTIONAL VIEW OF HIGH-SPEED CYLINDER AND STEAM CHEST.

drive. The intermediate receiver is mounted on the low-pressure cylinder, but this, of course, is a detail susceptible to much variation. The arrangement of the cylinder feet and dash-pots of the two cylinders is the same as that of the single-cylinder engine just described. The high-pressure cylinder is bolted to the low-pressure cylinder through a cylindrical distance piece, the flanges of which are of the same diameters as the cylinders themselves, and the rear cylinder is mounted on guides which allow it to slide in response to the expansion and contraction of the structure.

MERCURY VAPOR CONVERTER.

A 30-ampere mercury vapor converter for changing single-phase alternating current of 60 cycles to 120-volt direct current is shown by Fig. 1 herewith.

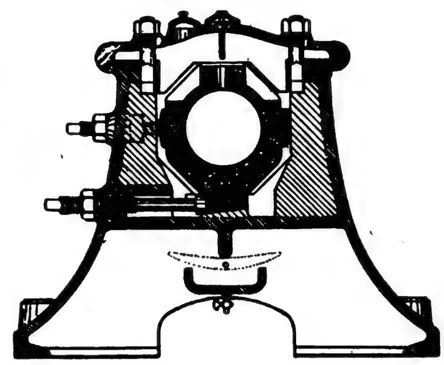

FIG. 9.—MAIN BEARING FOR DIRECT-CONNECTED MURRAY ENGINE.

The apparatus illustrated, which is made by the Cooper Hewitt Electric Company, of New York City, consists of a glass bulb about 9 ins. in diameter enclosed and mounted in a suitable holder. A small switchboard is mounted on the front, on which are placed a direct-current ammeter and a voltmeter, two switches and a current regulator. No special care is necessary in its manipulation, since there are but few moving parts, with little or no chance of these getting out of order. As compared with a motor-generator set, the cost of the converter is less and its efficiency greater. The outfit is automatic in its action, starting with the closing of the alternating and direct-current circuits. The apparatus may also be rendered non-automatic by the opening of a switch.

With alternating-current voltages not exceeding 450 volts, an autotransformer is used to obtain the proper potential for operating the converter. On higher voltages a transformer with separate primary and secondary is used. The maximum capacity of the converter is 30 amperes continuous running, and the current is adjustable as low as six amperes. The converter may be adapted to any direct-current voltage up to 120 volts.

The converter itself has a number of interesting characteristics. Its vacuum is similar to that of the mercury vapor lamp; but since it is not intended to give light, its length is as short as possible. The voltage across the converter, which represents its total resistance, is therefore reduced to 10 or 15 volts. As in the mercury vapor lamp this voltage is practically constant regardless of current except where this is small. With large currents in the container a considerable amount of heat is developed within the enclosing chamber, which must be dissipated. The container itself must therefore be made of considerable size to get the proper cooling surface. The mercury of the negative electrode is evaporated during the operation, and condenses on the surface, flowing back again to the electrode.

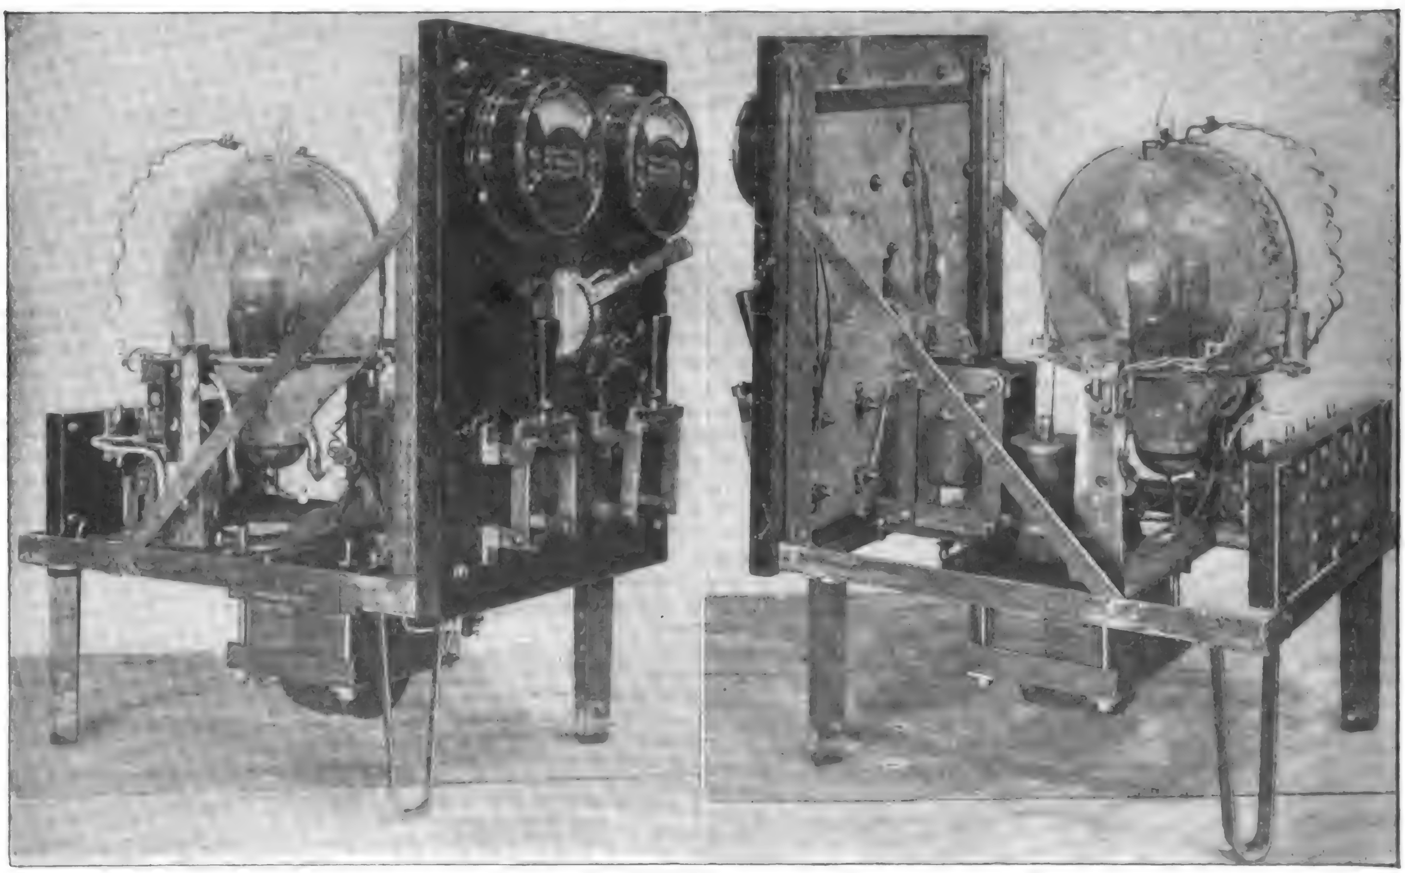

FIG. 1.—FRONT AND REAR VIEWS OF COOPER HEWITT MERCURY VAPOR CONVERTER.

New Apparatus and Appliances

QUEEN STAND PIPE RHEOSTATS.

Queen & Co., of Philadelphia, Pa., have recently designed a series of rheostats consisting of a continuous length of wire wound spirally on an iron stand pipe, about 6 inches in diameter, of a length depending on the total resistance and the current carrying capacity required. The wire is insulated from the iron pipe to withstand an alternating potential of 1000 volts. The pipe is closed at the bottom and by means of a small pipe, on either side of the base, a stream of water can be introduced for cooling purposes. If the rheostats are not used at their maximum capacity, water is not necessary; when only used at their maximum capacity for a few minutes at a time the pipe filled with water, alone, is sufficient; running water is recommended only when the rheostats will have hard continuous service at their maximum rated capacity. The stand pipe is mounted on a hardwood base, provided with casters, so as to be easily moved about. Mounted parallel to the upright pipe is an angle iron guide, which carries a slider, to which are attached phosphor bronze springs, which, in turn, make contact against the wire on the pipe. All the parts are insulated except a rod in the center of the angle iron guides, which is connected with the phosphor bronze springs by means of a split brass sleeve in the wooden handle. This allows adjustments of the current by almost infinitesimal steps.

FIG. 1.—STAND PIPE RHEOSTAT.

These rheostats are recommended by the builders for laboratory work in electrolysis, where it is necessary to secure fine graduations of both current and potential. To secure a potential regulation, the rheostat is supplied with two sliders, the terminals of the main conductor are connected with the main current source and the wires to the apparatus are connected to the two sliders. By putting the sliders close together, the difference of potential is very small, whereas, by sliding them farther apart, it can be increased to any desired point. The rheostats are made in several sizes.

GAS ENGINE DRIVEN GENERATOR.

The Rochester Electric Motor Company, of Rochester, N. Y., has brought out a line of machines especially designed for gas engine drive, one of which is illustrated by Fig. 2 herewith. The frame is of cast iron and unusually heavy, and in all but the smaller sizes the poles are built up of punchings of annealed sheet steel. The armature core is built of thin, carefully annealed discs, mounted directly upon and firmly keyed to the shaft, which is of large diameter and properly proportioned to safely carry the flywheel without any outboard bearing. Carbon brushes are used. The bearings are of phosphor bronze, self-aligning, and provided with ring oilers, which feed the oil to spiral grooves. Reservoirs of ample capacity are provided with overflow gauges. Shields or grooves upon the shaft return all surplus oil to the reservoirs. The dynamos may be operated either as compound-wound, constant potential machines for lighting, or as shunt-wound, variable potential machines for charging batteries by making the proper connections at the switchboard. The machines are built in sizes ranging from .8 kilowatt to 20 kilowatts, with speeds from 1400 to 950 r.p.m., and for e.m.f.'s of 115, 230 and 500 volts.

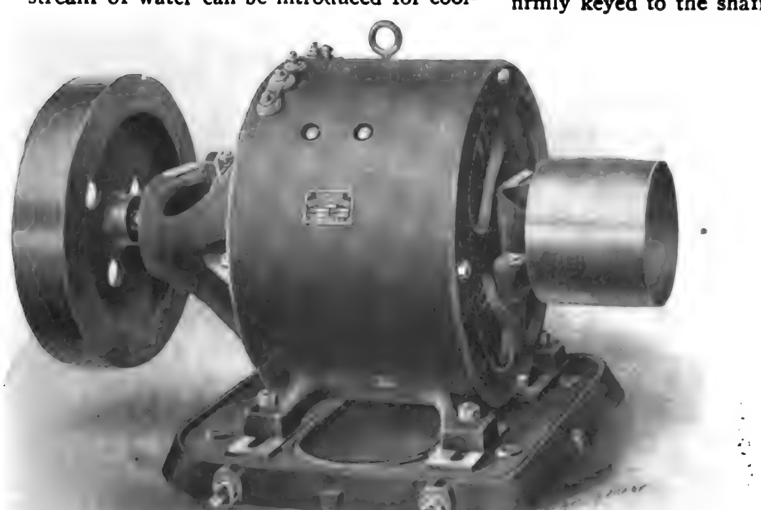

FIG. 2.—GENERATOR FOR GAS ENGINE DRIVE.

NEW RECEPTACLE AND ATTACHMENT PLUGS.

H. T. Paiste Co., Philadelphia, has just placed on the market a new style of its Fielding receptacles which is adapted for 3-wire molding. The problem for a long time has been to design this so that, although the receptacle was to be wired alternately on the negative and positive wires of the 3-wire system, in each case the lamp opening should be central with the line of molding. By an application of the Fielding receptacle principle the company has succeeeded in doing this and has ready for the market the receptacle shown by Fig. 3. After the receptacle is wired on either of the outside wires, it is simply turned end for end and it is then wired on the other one. The company has also put out a new line of "P-K" attachment plugs for 1905. These include a new style of the well-known brass-cap type, with a cap to take standard lamp-cord. The full line now includes brass-cap for standard lamp-cord, brass-cap for re-inforced lamp-cord and porcelain cap.

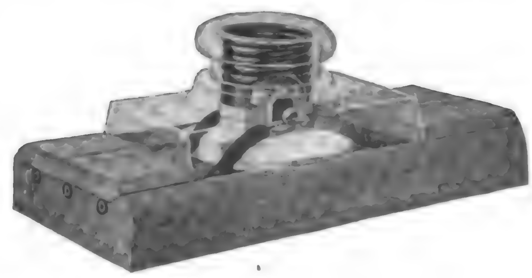

FIG. 3.—MOULDING RECEPTACLE.

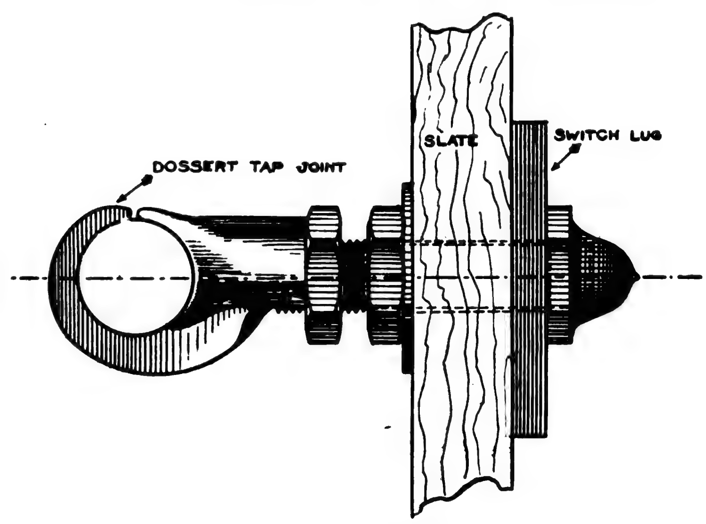

FIG. 4.—BUS-BAR SUPPORT.

DOSSERT BUS-BAR SUPPORT.

Dossert & Co., New York, have added to their line of solderless electrical connectors a bus-bar support for use in connection with round busses. The support, which is shown

in Fig. 4, is a modification of their standard cable tap. The principal member of the device is a substantial hook-shaped piece, machined to fit the bus-bar. A suitably shaped casting, which fits in the space between the bar and the base of the hook, and which is brought up snugly by means of a nut, holds the bus-bar securely in place. The shank of the hook is extended to form a stud long enough to pass through the board and the switch lug. The support is held in place in the usual manner by means of nuts on the front and back of the board. The manufacturers also make a support of similar character, but having the stud integral with the switch lug.

WESTINGHOUSE "TYPE R" DIRECT-CURRENT BIPOLAR MOTORS.

A line of direct-current motors known as "Type R" has been produced by the Westinghouse Electric & Manufacturing Company. These are constructed in sizes from one-sixth to one and three-quarter horsepower and wound for 110 and 220 volts. The fields are shunt-wound. The yoke, brackets and poles are cast in one piece. The bore of the bearing housing supports is the same as that of the field poles. Accordingly, the armature can be removed by simply taking out one bearing housing and this may be done without removing the pinion or pulley, unless it is larger in diameter than the bore of the field poles. The front end bracket is formed by three arms, which afford protection to the commutator, but leave openings through which ready access to the brushes may be obtained. The two poles project inward in a horizontal plane and are magnetized by machine-formed coils. These coils are treated with both a weatherproof and an insulating compound, and are covered with a number of thicknesses of tape to guard against mechanical injury. The coil supports are small L-shaped pieces of sheet brass which are fastened to the poles by screws and which hold the coils firmly in place. The bearings are of the ring self-oiling type, with linings of phosphor-bronze, mounted in separate housings which may be adjusted in any position, so that the oil reservoirs hang vertical whether the motor be set upon the floor or suspended from the wall or ceiling. Creeping of oil along the shaft is prevented by the use of a properly designed oil-thrower or wiper which protects the commutator and armature. The oil reservoirs are of ample capacity and the oil rings are easy to inspect, as they may be seen from the opening in the bearing housing. The motors are usually furnished without bed-plates, but may be supplied with bed-plates of the universal type, equipped with drip-pans and belt-tighteners and arranged for wall or ceiling suspension as well as for floor mounting. The armatures are of the slotted drum type with imbedded coils which are

FIG. 5.—PARTS OF WESTINGHOUSE TYPE R MOTOR.

retained in the slots by hard fibre wedges, without band wires of any kind. The armature cores are formed of circular punchings of carefully annealed soft steel. They are mounted upon shafts which are so designed that pulleys or pinions may be secured with keys. The leads to the commutator are adequately protected by a covering of treated cloth and tape. The brush-holder arms are mounted upon rings which are supported at three points inside the motor frame. The individual holders are of the sliding type with the rod construction. Pressure on the brush is exerted by a coiled spring. The carbons are said to be held radial at all times, there being no swivel action, it is claimed, during the operation of the machine. The commutators are built up of hard-drawn copper bars assembled upon brass bushes. They are made without necks. The terminals are of the brass bolt and nut construction and are located on the two lower arms of the front end brackets. The bolt or stud is threaded on both ends and is brought through insulated bushings and clamped into position by a nut on either side of the arm. These nuts are properly insulated by vulcabeston washers. Another nut on either end of the stud serves to fasten the leads. No porcelain is used in the construction of these terminals. They are easily accessible and are largely protected from accidental short-circuit or other injury by their position. The starting rheostats furnished with these motors are of approved design, with automatic no-voltage release. They are small and compact and fireproof throughout. The resistance is of the bar-wound type with porcelain insulation to ground, and is thoroughly ventilated. The adjustment is said to be such that the motor starts without jar or abnormal rush of current.

THE BEST PATENT ADJUSTABLE WEDGE GATE VALVE.

Fig. 6 herewith shows the patent adjustable wedge gate valve made by the Best Manufacturing Company, of Pittsburg, Pa., and used in many of the large power houses. The sectional view shows the wedge in the same form as the solid taper wedge, except that it is in two parts, there being a ball joint on the inner surfaces the entire circumference of the wedges. The manufacturer claims the valve to be positive seating and adjustable. The wear can be taken up from time to time and the renewable feature is said to make the valve very

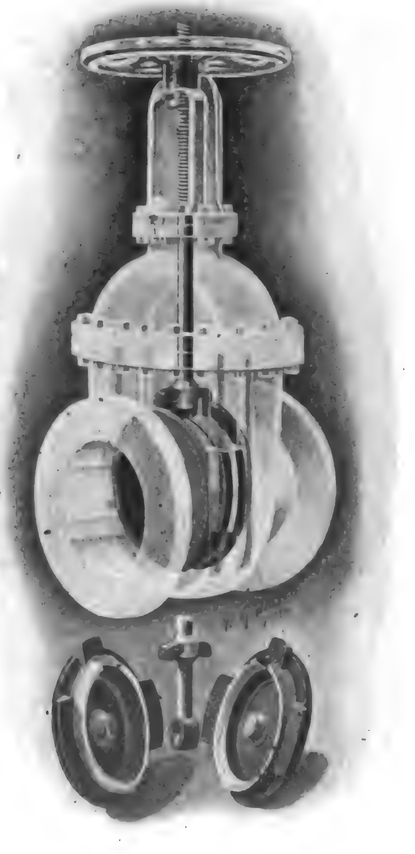

FIG. 6.—ADJUSTABLE WEDGE GATE VALVE.

durable. Rails or guides are cast in the body on either side, and wings are cast on either side of the wedges which fit inside of these guides or rails. This precludes the possibility of the valve becoming disarranged. It will be noted that there are

wings cast on the top edges of the wedges, and also a collar with guides, cast on the spindle. The valves are said to be so constucted that they have no more parts than

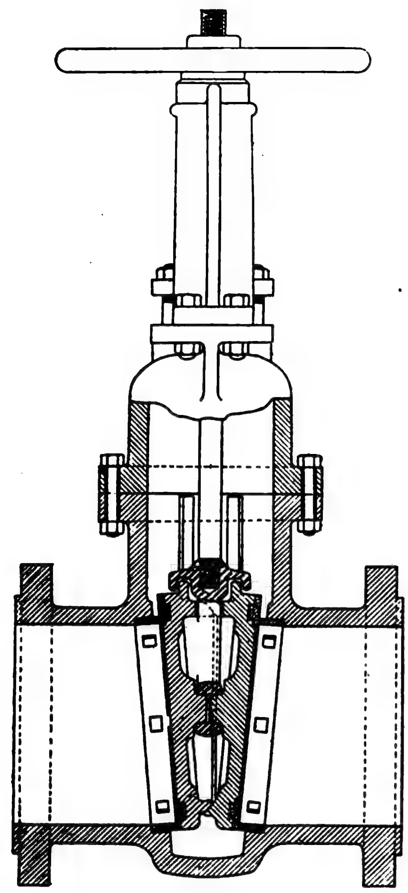

FIG. 7.—SECTIONAL VIEW OF GATE VALVE.

a solid taper wedge gate. The wedges have bronze facings; and the bronze seats are claimed to be screwed up in such a manner as to leave no pockets in the rear for the water and steam to attack the threads. The method of seat construction avoids some very bad features existing in gate valves. The mechanical construction of the valves, the manufacturer maintains, makes them especially fitted for all classes of service, particularly high pressure and superheated steam service.

A COMPACT GENERATING SET.

The B. F. Sturtevant Company, Boston, Mass., has brought out for torpedo boat service and similar duty the small generating set illustrated herewith. It comprises a single-cylinder engine and direct-current generator, standing less than 30 inches high and having an output of 3 kilowatts. The engine cylinder, which is 3½ inches diameter by 3 inches stroke, is cast with the frame. The reciprocating parts are completely enclosed, but are readily accessible through an opening which is normally covered by a removable plate. The main bearing measures 1 7-16 inches diameter by 3⅛ inches in length. A balanced piston valve controls the steam distribution, and is operated by a Shepherd governor attached to the flywheel and giving a regulation of 1½ per cent. from full load to no load. The cross-head is of the slipper type adjustable for wear and provided with a pin ¾ inches diameter by 1½ inches long. A forked end connecting rod and a 1¼-inch by 1½-inch crank-pin are employed. Designed for extremely high-speed and continuous service, this engine has proved remarkably quiet in operation, and particularly suited to modern yacht and similar service.

The generator is of the four-pole type, designed to run at full output continuously, and embodies the best features of modern dynamo construction. The current densities are low, and ample ventilating ducts are provided. The machine is compound-wound, and capable of carrying 50 per cent overload for short periods of time without shifting of brushes or flashing at the commutator. It will carry a continuous overload of 25 per cent without undue heating or sparking. After a continuous run of ten hours at full load, the increase in temperature above that of the surrounding atmosphere is guaranteed not to exceed 40° Centigrade in any of its parts. The insulation is of the best. It is subjected to a test e.m.f. of at least 1500 volts for a period of one minute before being shipped, the insulation resistance as measured by a voltmeter, not being allowed to fall below 1 megohm. The magnet frame is of steel parted horizontally and has removable magnet poles of wrought iron with cast-iron shoes. The poles are attached to the magnet frame by through bolts, and each pole carries a shunt and a series coil.

The armature is of the slotted-core ventilated drum type, having a core of special low steel or charcoal iron mounted upon a cast iron spider which has a hub extension for the support of the commutator which is constructed of drawn copper segments, held in a cast-iron shell of spider construction and clamped with a steel ring. Only the best and most carefully selected mica is used between the segments. The end insulation consists of micanite rings. The coils are form-wound and individually insulated. The brush-holders are of the box type, and are mounted upon studs supported from the brush arm. Each brush and holder is separately adjustable and readily removable for cleaning and repairs.

HIGH-TENSION STRAIN INSULATORS.

Two forms of high-tension strain insulator are shown by Figs. 9 and 10 herewith. These are made by the Locke Insulator Manufacturing Company, of Victor, N.

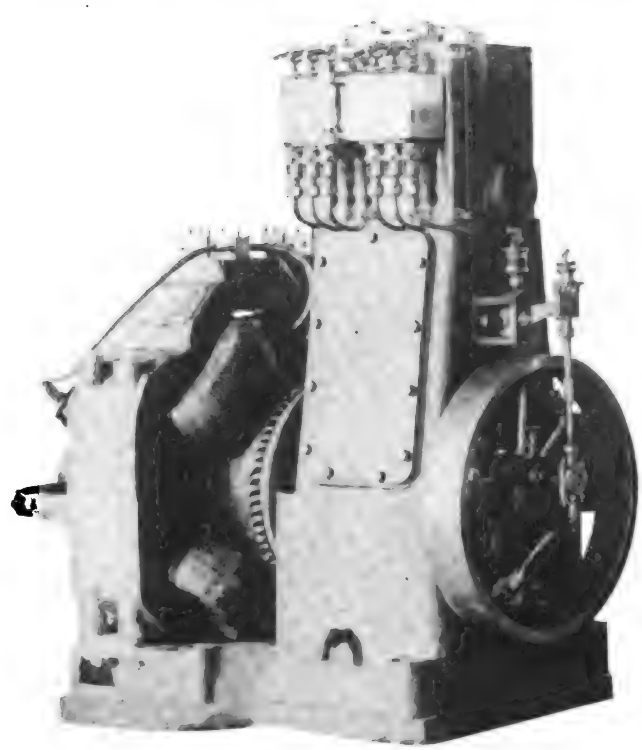

FIG. 8.—COMPACT GENERATING SET.

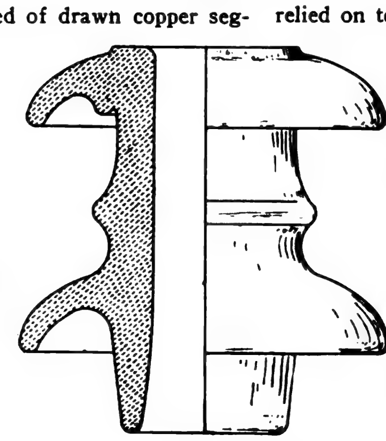
Y. The increase in the use of high-tension electric railways will naturally call for insulators capable of withstanding high mechanical as well as high electrical strains. The strain insulator shown by Fig. 9 is 6 ins. high and 5¾ ins. in diameter and has been designed for voltages as high as 8000. The company has also developed a smaller strain insulator for voltages of 5000 and under, which is useful in the construction of spans for trolley suspension. The company now has a complete line of strain insulators for voltages up to 35,000 and is developing a new design for voltages of 60,000 or more. With regard to the mechanical strength of the insulators, the company states that the larger designs can be relied on to withstand a breakdown test of



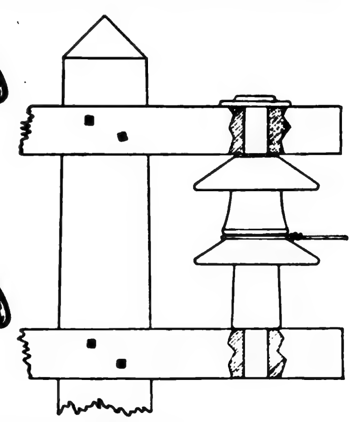


FIG. 9.—STRAIN INSULATORS.—FIG. 10.

approximately 12,000 lbs., with the insulator supported by a pin passing through the middle and the strain applied around the middle wire groove. In connection with

these insulators the company has also developed a method of using them whereby almost any strain up to several tons may be applied with safety.

SABLE RAWHIDE BELTING.

The Sable rawhide belting made by the Shultz Belting Company, of St. Louis, Mo., is made from selected rawhide said to be tanned so as to produce a surface very pliable and yet leaving underneath the long

FIG. 11.—SABLE RAWHIDE BELTING.

fibers that make it tough, unbroken and unseparated. The manufacturer claims that it will transmit a third more power than the best oak-tanned belt and last longer. Sable rawhide belting of double thickness, the maker claims, will turn around as small a pulley as oak-tanned leather belting of single thickness. Fig. 11 herewith gives an idea of the flexibility of the belting. This, the manufacturer maintains, is easily done with Sable belting of double thickness.

EXPERIMENTAL DYNAMOS.

Fig. 12 herewith shows the Midget dynamo, equipped with hand power made by the Elbridge Electrical Manufacturing Company, of Elbridge, N. Y. The dynamo has

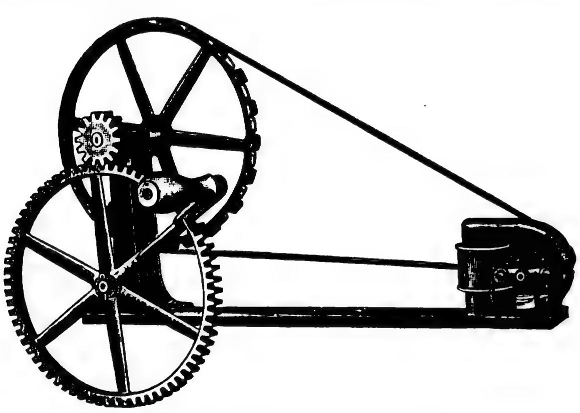

FIG. 12.—EXPERIMENTAL DYNAMO.

an output of 10 watts, and is wound for 4, 8 and 10 volts. The hand power device is suitably geared so as to give the required speed without too much exertion on the part of the operator. The entire outfit is mounted on a wooden base.

NEW BOOKS.

HOME MECHANICS FOR AMATEURS. By George M. Hopkins. New York: Munn & Co. Cloth. 370 pages, 5½ inches x 8 inches; 326 illustrations. Price, $1.50.

The compiler of this book, and author of many of its chapters, had a positive genius for the class of work represented by the book, and the contents are typical of his best efforts in this field. The book contains full illustrated instructions for making a large number of specific pieces of machinery and apparatus, together with three chapters on wood-working, metal-working and making household ornaments. It will be found of great interest by any intelligent amateur and of considerable value in some respects to the skilled amateur mechanic.

THE ELECTRICAL TRANSMISSION OF ENERGY. By A. V. Abbott. (Fourth Edition.) New York: D. Van Nostrand Company, 1904. Cloth. 675 + xxx pages, 6 inches x 9 inches; 367 illustrations; numerous tables and charts. Price, $5.

This edition of Mr. Abbott's well-known work shows evidence of most comprehensive revision, and has been brought thoroughly up-to-date excepting in a very few instances. Notable lapses in this respect occur on page 352, where resistances are given in obsolete "Legal" ohms and B. A. units only; on page 448 *et seq.*, where *J* is used to represent impedance, instead of *Z*; in table No. 72, where useless impedance factors for lines are given; on page 519, where obsolete three-wire balancing apparatus is described, and on page 576 *et seq.*, where dynamomotors are called motor-transformers.

Mr. Abbott also uses the symbol *L* for both C. G. S. units of inductance and henrys; his statement on page 619, immediately beneath the table, as to the relative voltages of single-phase and three-phase lines, is exactly the reverse of the fact, and his statements in many places are too loose for incorporation in a book of the generally high grade of this one. The book, however, stands out far and away ahead of anything thus far published along similar lines. It is extremely broad in scope, logical in treatment and mostly accurate and satisfying. The author's few inaccuracies are obviously due to too implicit a trust in statements of other writers and not to any lack of rudimentary knowledge of the subject; in all cases they occur where verification would involve tedious mathematical deductions, indicating that the enormity of the author's undertaking wore on his patience and induced a little carelessness.

QUICK DELIVERIES OF ELECTRICAL APPARATUS TO MEXICO.

In order to enable the Mexican Light & Power Company to effect prompt temporary repairs to its generating station in the City of Mexico, which was recently partially destroyed by fire, two express shipments were made by the General Electric Company from Schenectady recently, which were remarkable, both for their size and prompt despatch. Telegraphic advices were received by the Foreign Department on Monday, February 6, stating that a large quantity of switchboard material would be required to enable the plant to resume operation, although at the time the full extent of the damage was not known. As a result of further telegrams, and consultations by telephone with the New York representatives of the Mexican company, details of the order were settled Tuesday morning, and on Wednesday, February 8, the second day from the receipt of information of the trouble, an express shipment of thirty thousand pounds of switchboard instruments, switches and supplies left the Schenectady factory for Mexico City. The shipment constituted a complete switchboard equipment for a 4000-kw. power station, and to collect and despatch the material in this short time taxed every resource of the company. While most of the instruments and switches were available at Schenectady, it was necessary to obtain instrument transformers by express from Lynn, and four large rheostats for generators of German make had to be entirely built from data telegraphed from Mexico. In addition, a large quantity of wire and cable, which could not be supplied from the Schenectady stock, had to be borrowed from an installation which the General Electric Company was carrying out in New York City.

In handling the shipment from Schenectady, special arrangements were made with the railroad companies to obviate transhipments in passing from one system to another, and especially in crossing the Mexican frontier, and, in addition, a special messenger traveled with the car the entire distance to see that no delays occurred at junction points. The shipment reached Mexico City on Tuesday, February 14, thus placing in the hands of the customer, within seven days from receipt of the first news of the disaster and from a factory over 3700 miles away, a complete outfit of the new material necessary to restore the interrupted lighting and power service.

The fire also destroyed two engine-driven sets, making it imperative to install at once two 500-kw. Curtis turbine-generators that were on order at the time, and one of which was due to arrive by freight in a few days. The second turbine had just been loaded on a freight car at the Schenectady factory, but the urgent need of the machine decided the Mexican company to authorize its shipment by express. Of this shipment the turbine proper, as boxed, weighed 27,000 lbs. and occupied a space 8 ft. high by 8 ft. wide by 9½ ft. long. The doors of the ordinary express car would not admit the entrance of a "package" of these dimensions, but a special car having large doors was secured, and by stripping the boxing to a minimum the loading was effected. The generator and other parts brought the weight up to nearly 43,000 lbs., making one of the heaviest single express shipments ever made.

OBITUARY.

S. L. BARRIETT, president of the Barriett Electric Company, Cincinnati, O., died recently at his home in Cincinnati after a short illness. Mr. Barriett was one of the "old-timers" in the manufacture of small dynamos and motors, and for several years past—since the formation of his Cincinnati company—has also given his attention

to the design and manufacture of larger machines.

F. A. LA ROCHE, the well-known manufacturer of electrical apparatus, died at the Presbyterian Hospital last month of cancer of the stomach. He had been actively interested in the electrical industry since 1885, and was an inventor of considerable merit. During the pasts few years he became interested in the automobile industry, and made several remarkable runs in a car of his own manufacture.

C. C. WARREN, president and treasurer of the Warren Electric & Mfg. Company, Sandusky, Ohio, died on March 22, aged 70 years. Mr. Warren was one of the pioneers of the electrical industry, and prior to taking up manufacturing became prominent as a sales manager representing in the West at one time or another several of the important manufacturing companies. In closing out his electrical interest in the West as representative, Mr. Warren went to Sandusky, where he established the Warren Electric & Mfg. Company, of which he was the head until his death. Socially Mr. Warren was a man of most excellent qualities and was enthusiastic in promoting the welfare of his wide circle of friends and the community in general.

PERSONAL.

MR. W. H. WHITESIDE has been elected vice-president of the Allis-Chalmers Company, to succeed Mr. W. J. Chalmers, who recently resigned that position.

MR. WILLIAM KENT, Dean of the Syracuse University's College of Applied Science, is the author of a highly interesting paper on "The Engineer and His Education," which has been published in pamphlet form by the University.

MR. H. N. LATEY, of the engineering staff of the Interborough Rapid Transit Company, has been appointed Electrical Engineer of the company, his jurisdiction now covering both of the divisions of the system of the Interborough Company.

MR. C. H. NORWOOD has been appointed the Chicago representative of the Robbins & Myers Company, Springfield, O. Mr. Norwood's headquarters are at 1107 Fisher Building, where a stock of "Standard" dynamos and motors will be carried.

MR. E. A. SCHROEDER, who has been connected with the Crocker-Wheeler Company's St. Louis office for some time past, has been appointed manager of the company's New Orleans office, to succeed Mr. Field, who has been transferred to the Boston office.

MR. F. D. PHILLIPS, of Chicago, has been appointed general manager of the American Electrical Supply Company, of the same city. Mr. Phillips is an old Electrical Appliance man, and more recently was treasurer and sales manager of the Crescent Company.

MR. J. H. HALLBERG, the well-known arc-lighting specialist, has been engaged in a general advisory capacity by the New York commission on municipal lighting. The commission is evidently trying to make the best of a tough proposition by getting high-grade technical assistance.

MR. CHAS. D. KNIGHT has been appointed chief engineer of the American Electric & Controller Company, New York. Mr. Knight is widely experienced in the design and manufacture of electrical apparatus, having been on the staffs of the General Electric, Fort Wayne, National Electric and Cutler-Hammer Companies.

MR. ARTHUR WILLIAMS, of the New York Edison Company, has been appointed by President Ernest H. Davis, of the National Electric Light Association, to make a report at the Denver convention on "Municipal Ownership." It is needless to say that the report will undoubtedly be thorough and of extreme interest to central station men.

MR. CAMPBELL SCOTT, whose resignation of the general management of the C. & C. Electric Company was announced recently in this column, has been appointed director of the Yonkers works of the Otis Elevator Company. The company has our sincere congratulations on its acquisition of Mr. Scott's services; by natural ability and wide experience he is eminently qualified for the work.

MR. GARDINER C. SIMS, of Armington & Sims fame, has been appointed general manager of the Marine Engine & Machine Company. This company will take up the manufacture of the high-speed automatic engine designed by Mr. Sims and formerly built by the Armington & Sims Company. The design has been, of course, modified in details to correspond with the progress that has been made in the building of such machinery since the old company was actively in the field, but the fundamental characteristics will be retained. Entirely new patterns have been prepared.

MR. WALTER RAMSEY, who recently assumed the general management of the American Arc Lamp Company, successor to the Lea Electric Mfg. Company, Elwood, Ind., has practically revolutionized the company's business and raised the concern from a struggling position to one in which a splendid business is being enjoyed and the prospects for the future are most gratifying. Mr. Ramsey is a resident of Indianapolis, and has had an extensive business experience which he has applied to the affairs of the company—with the usual results. The company will probably move into its new factory at Kalamazoo, Mich., about the middle of May. Up to that time it will remain at Elwood.

TRADE PUBLICATIONS.

FLANGE JOINT GASKETS. H. W. Johns-Manville Company, New York.—A vest-pocket pamphlet devoted to "Kearsarge" flange joint gaskets.

CURTIS STEAM TURBINE. General Electric Company.—Publication No. 9137, of octavo size, containing illustrations of notable turbine installations.

CENTRIFUGAL PUMPS. De Laval Steam Turbine Company, Trenton, N. J.—A very complete publication containing a fully illustrated description of the De Laval centrifugal pumps.

STEAM BOILERS. The Brownell Company, Dayton, O.—An illustrated catalogue of standard size, devoted to the Brownell vertical and horizontal tubular boilers and sectional water-tube boilers.

MOTOR GENERATOR SETS. General Electric Company.—A handsome pamphlet of actavo size, containing illustrations and tabulated data of G. E. motor generators, together with views of some typical installations.

KAISLING PROTECTORS FOR TELEPHONE CIRCUITS. American Electric Fuse Company, Chicago.—A standard-size catalogue containing an illustrated description of self-soldering and self-restoring telephone-circuit protectors.

ENGINEERS' CHUMS. Mound Tool & Scraper Company, St. Louis, Mo.—This is the seventh edition of this little pamphlet, which is devoted to a description of the well-known Mound scraping tools, packing tools, cold chisels, etc.

ELECTRIC FAN MOTORS. Sprague Electric Company, New York.—Bulletin No. 309, consisting of a pocket-size pamphlet containing an illustrated list of the well-known Lundell and other fan motors made by the Sprague Company.

TRANSFORMER THRIFT. Moloney Electric Company, St. Louis, Mo.—A vest-pocket booklet, containing some forcible arguments as to the merits of Moloney transformers. The arguments are illustrated by some rather clever sketches.

TRANSFORMERS. The Crawfordsville Electric Company, Crawfordsville, Ind.—A handsomely executed catalogue of moderate size, containing a well-illustrated and detailed description of the Hornberger-Irwin transformers built by this company.

A MODERN INDUSTRIAL PLANT. Dodge & Day, Philadelphia.—Bulletin No. 175, in which the plant of an iron-working establishment at Hazleton, Pa., is illustrated as a typical example of the "modernizing" work of this progressive firm of engineers.

FAN MOTORS. General Electric Company.—The 1905 edition of this company's fan-motor catalogue, designated Publication No. 1048. The book is a beautiful specimen of trade literature; engravings, typography and presswork are all of the highest grade.

ECONOMIZING STEAM SPECIALTIES. The Williams Gauge Company, Pittsburg, Pa.—An illustrated catalogue of safety feed-water regulators, steam-operated traps, steam pump governors and safety water columns. The book is finely executed, especially as to the illustrations.

REYNOLDS-CORLISS ENGINES. Allis-Chalmers Company, Milwaukee, Wis.—Catalogue No. 120 of small-octavo size, containing illustrations of the varied line of Reynolds-Corliss steam engines. The book is executed in the ornate style characteristic of this company's literature.

AUTOMATIC STEAM PUMP AND RECEIVER. The Geo. F. Blake Mfg. Company, New York.—Bulletin B-81, containing an illustrated description of the Blake automatic pumping outfit for draining steam coils, jackets, etc., and returning the water of condensation to the boiler.

COMBINED BLOW TORCH AND SOLDERING IRON.—Emmelmann Bros. Mfg. Company, Indianapolis, Ind.—A vest-pocket pamphlet relating to an extremely ingenious soldering iron, the handle of which contains a blow torch that delivers its flame directly on the copper of the tool.

GAS AND OIL ENGINES. De La Vergne Machine Company, New York.—An ornate folder containing illustrations of the Koerting gas engines and Hornsby-Akroyd oil engines built by this company, together with a brief argument in favor of internal-combustion engines as compared with the steam engine.

MODERN HYDRO-ELECTRIC POWER STATIONS. J. W. Rickey, Minneapolis, Minn.—An octavo-size pamphlet containing illustrations and descriptive data of some notable plants in which the penstock construction advocated by Mr. Rickey has been employed by him. This construction is of concrete and steel.

TELEPHONE APPLIANCES. American Electric Fuse Company, Chicago.—This is a well-executed, pocket-size pamphlet containing illustrations of the comprehensive line of telephone-circuit protecting devices made by this company, excepting the American self-soldering protectors, which are described in a separate catalogue.

COMPRESSED FACTS ABOUT COMPRESSED AIR. Clayton Air Compressor Works, New York.—A finely executed booklet of vest-pocket size, designated Bulletin C-202, and containing a summary of the points to be considered in buying an air-compressor of medium capacity. The merits of the Clayton compressor are presented convincingly.

THE LIGHTING OF LARGE OFFICE BUILDINGS AND STORES. Holophane Glass Company, New York.—This is a companion to the beautiful little publications on illumination which were noted in this column a few months ago, and it is prepared in the same artistic style as the other two booklets. The character of the subject matter is indicated by the title.

BUSINESS NEWS.

THE BARRIETT ELECTRIC COMPANY, Cincinnati, O., announces that the death of its president will not cause any change in the policy of the company; its affairs will be continued as heretofore by the same general management.

CLAUDE T. LLOYD, Fremont, Mich., has purchased from the municipality its electrical supply department, and will carry in stock a full line of general supplies, as well as some attractive specialties, for the convenience of the trade in Western Michigan.

THE DODGE COAL STORAGE COMPANY, New York, has acquired the busines of the United Telpherage Company, of New York. Communications intended for the latter company should be addressed to the United Telpherage Department of the Dodge Coal Storage Company, 49 Dey Street.

THE MURRAY CORLISS ENGINE, which was exhibited at the St. Louis Exposition, is the subject of a page-long article and a two-page illustrative supplement in a recent number of *La Revue Industrielle, Paris*. The merits of the Murray Iron Works Company's product are evidently appreciated abroad, as well as in this country.

FRANCE PACKING COMPANY, Tacony, Pa., after a long series of experiments, has brought

out a metallic packing for gas engines which is sold under the same conditions as the well-known France packing for steam engines and pumps, namely, the coupon system, by means of which an engineer can gradually equip his plant with a full outfit of tools without cost to himself.

PARTRICK, CARTER & WILKINS, Philadelphia, have moved into their new factory, at 22d and Wood Sts., where practically twice the floor space will be available that was afforded by the old quarters. The demand for this firm's annunciators and other house goods shows the steady growth indicative of all product "sold on merit."

QUAKER CITY RUBBER COMPANY, Philadelphia, continues to receive flattering letters about its P. P. P. packing for piston rods, valve rods, etc. The chief engineer of the Polar Star Electric Company, Faribault, Minn., wrote some time ago as follows: "We ran one set of your P. P. P. packing on the main rod two years and 9 months, adding during this period one ring. I have used every known packing on the market, but never have been able to secure such service from any of them."

DOSSERT & COMPANY, New York, manufacturers of solderless electrical connectors, report that they have supplied L. T. Comstock & Co. with all the terminals for the panel-boards throughout the new Trinity Building, New York. The terminals, 380 in all, vary in size from No. 10 B. & S. gauge to 500,000 circular mils., cross-section. A number of Dossert connectors were recently shipped to Dr. Giorgio Finzi, Milan, Italy, for the equipment of the first large (400-h.p.) car for the Valtellina single-phase railroad.

THE CUTLER-HAMMER MANUFACTURING COMPANY, Milwaukee, Wis., has received an order from the Northern Electrical Manufacturing Company, Madison, Wis., for 135 of the new type of C.-H. machine-tool motor controllers, equipped with fuses and switch in conformity to the U. S. Navy specifications. All of these controllers will be installed in the plant of the Winchester Repeating Arms Company. Although this controller has been on the market but a few months, its sales have far exceeded the most sanguine expectations of the company.

BARTZ, WYGANT & BROWN, Hornellsville, N. Y., have one of the most modern and thoroughly equipped shops in central New York. The machine shop and erecting department are on the first floor; the winding, painting and drafting departments and the offices are on the second floor, and the stock and shipping rooms in the basement. The machinery is all motor-driven, the motors being supplied by B. W. & B. generators, belt-driven by a gas engine. The company's dynamos and motors are steadily making friends throughout the trade.

THE STROMBERG CARLSON TELEPHONE MFG. COMPANY, Chicago and Rochester, reports that the Tri-State Telephone Company, Grand Forks, S. D., recently began giving commercial service from the exchange installed by the Stromberg-Carlson Company, and has an excellent list of subscribers right from the start. Contracts for switchboards have been closed with exchange companies at Fairpoint, O.; Illinois City, Ill.; Maple Lake, Minn.; Lathrop, Mo.; Granger, Tex.; Toledo, O.; Parnell, Ia.; Carmi, Ill.; and Philadelphia, Pa., as well as one with the Curtis Publishing Company, Philadelphia, for a central energy switchboard of the most modern type.

THE REEVES ENGINE COMPANY, Trenton, N. J., closed orders recently for a 16x16 horizontal engine for the Kansas City, Mo., City Hall; an 18x16 horizontal for the Sayville (L. I.) Electric Company; a 14x14 for the city lighting plant at Cedar Rapids, Iowa; a 6x7 vertical for the West Virginia Pulp & Paper Company, Tyrone, Pa.; two 12x12 horizontals for the Philadelphia works of George Hememant Company; a 10x9 vertical for Swift & Co., Brooklyn, N. Y.; two 12&20x16 vertical cross compounds for Ben Stanley Revett, of Denver, Col.; two 10x9 verticals for Farr-Alpaca Company; a 16&26x18 vertical cross compound for the City Hospital at Philadelphia, and numerous others.

PITTSBURG GAGE & SUPPLY COMPANY, Pittsburg, Pa., recently sold White Star continuous oiling systems to the Western Electric Company, Chicago; Chicago Consolidated Traction Company, Chicago; Northern Texas Traction Company, Handley, Tex.; Kremming Real Estate Company, St. Louis, Mo.; American Steel & Wire Company, Cleveland, O.; International Bank Building, New York, and Wyoming Shovel Company, Wyoming, Pa. A careful test conducted by the Massachusetts Mills in Georgia, Lindale, Ga., where a White Star oiling system was installed two years ago, is said to have developed the fact that the elimination of hand oiling by this system on an engine of 2000 horse-power has produced a saving of about 75 per cent. in the oil consumption.

THE PEERLESS ELECTRIC COMPANY, Warren, Ohio, reports the recent sale of a special laboratory generator to the Bliss Electrical School, Washington, D. C., and a number of motors to the Massachusetts Institute of Technology, Boston. An installation of thirteen press motors has just been furnished A. I. Root, Inc., Omaha, Neb.; an equipment of generator and twelve motors for the School News at Taylorville, Ill. Among orders just secured may be noted one for equipping the plant of the Oil City (Pa.) Derrick Publishing Company with a generator and eleven motors; eleven motors for the printing house of Nitschke Bros., Columbus, Ohio; S. Barker & Sons, printers and stationers, Cleveland, Ohio, six motors; and eleven linotype motors for the Manitoba Free Press, Winnipeg, Man.

MORE BIG CROCKER-WHEELER ALTERNATORS.—An order for four 4000-kw. three-phase, sixty cycle, 6600-volt alternating current generators, with exciters, has just been placed with the Crocker-Wheeler Company, Ampere, N. J., by the trustees of the Sanitary District of Chicago. These are to be driven by Wellman-Seaver-Morgan horizontal water-wheels and put in operation at Lockport, Ill., the western end of the Chicago Sanitary and Ship Canal. This is the second contract secured by the Crocker-Wheeler Company for large alternators. It will doubtless be recalled that the California Gas & Electric Corporation recently placed an order for three 4000 K.V.A. Crocker-Wheeler alternating current generators, to be driven by gas engines, which will supply current for all the street railways in San Francisco.

LAGONDA MFG. COMPANY, of Springefild, Ohio, manufacturer of the well-known Weinland tube cleaners and other steam and boiler-room specialties, now has branch offices in the following places: Pittsburg, Iron Exchange Building, Robert Gregory, manager; Philadelphia, Builders' Exchange, Jas. V. Davidson, manager; New York, 123 Liberty Street, C. A. Gillett, manager; St. Louis, 511 Missouri Trust Building, J. P. Maloy, manager. The company has the following selling representatives: Chicago, The Chicago Engineer Supply Company; San Francisco and Los Angeles, Chas. C. Moore & Co.; Toledo, O., Hardy & Dischinger Company; Kansas City, Mo., E. D. Hornbrook; Peoria, Ill., Kinsey & Mahler; Indianapolis, Ind., Hide, Leather & Belting Company; London, Eng., Selig, Sonnenthal & Co. This information is given for the convenience of the trade; anything needed in the Lagonda line can be furnished promptly from any of these points.

THE BALL & WOOD COMPANY, the well-known engine builders of Elizabeth, N. J., are adding a new department to their business, that of flange welding and pipe bending. The increasing use of high pressure and superheated steam has developed the need of pipe joints which are absolutely reliable, and in the process the company is bringing out the use of forged steel flanges welded to the pipe is designed to eliminate two out of the three weak spots in every steam joint, the pipe and flange being made homogeneous. Contracts have been let for a new smith's shop at the Ball & Wood works for the purpose of doing this work and it is expected shortly to be in full operation. Mr. O. M. Jones has resigned his position in the New York sales office of the National Tube Company and become the manager of the new department. For information regarding this work letters should be addressed to the company's welding department.

ALLIS-CHALMERS COMPANY, Milwaukee, is landing important orders at a rate calculated to paralyze the vocal cords of any calamity howler. Among recent contracts may be noted a complete 2000-kw. power-house equipment, both steam and electric, for the Toledo Interurban Construction Company; machinery for entirely remodeling the power-house equipment of the Mansfield (O.) Railway, Light & Power Company; a 4000-kw. electrical equipment for the new power plant of the Turners' Falls (Mass.) Company; a heavy duty, cross-compound Reynolds-Corliss engine for direct connection to a 1500-kw. generator in the plant of the Detroit United Railway, and a complete engine and generator unit of 500 kilowatts capacity for the Wells Building Company, Milwaukee. The company will be represented hereafter in Western Australia by Mr. F. R. Perrot, whose headquarters will be at Perth. In New Zealand, the firm of John Chambers & Son, Ltd., at Auckland, is now looking after Allis-Chalmers interests.

THE STANDARD UNDERGROUND CABLE COMPANY, Pittsburg, Pa., announces that on account of the general growth of its business on the Pacific Coast, it has been decided to discontinue all agency arrangements and to open a branch office in the Rialto Building, San Francisco. Mr. A. B. Saurman is manager for the Pacific Coast territory, which includes Washington, Oregon, Idaho, California, Nevada, Arizona, British Columbia, Alaska and the Hawaiian Islands. Mr. Saurman has been connected with the Standard Underground Cable Company in both the construction and sales departments at Philadelphia and New York, and was later for several years manager of the Boston office; for the past two years his position has been that of manager of the Pacific Coast Sales Department. The company expects to make announcements soon of the location and personnel of sub-offices at Los Angeles and Portland. The factory at Oakland, Cal., (the only factory west of the Mississippi equipped with lead presses for cable work) has been unusually busy during the past six months, and the prospects on the Pacific Coast point to continued activity.

WESTINGHOUSE ELECTRIC & MFG. COMPANY reports a continuance of "big business." The following recent contracts speak for themselves: As an extension to its system the Louisville Railway Company will install two 750-kw., three-phase rotary converters, six 300-kw., air-blast transformers with blower outfits, and two switchboards. The United Railways & Electric Company, of Baltimore, has contracted for three 1000-kw. rotaries and nine 350-kw. air-blast transformers. These will operate on a 13,000 volt line, transforming to 330 volts. Eighteen rotary converters with a total capacity of 27,000 kilowatts, in 1000 and 1500 kw. units, will be placed in sub-stations of the New York Central Railroad Company. Two 1500-kw., direct-current generators will be built for the Carnegie Steel Company to furnish power for two 1500-h.p., 230-volt motors. For the protection of this apparatus, 10,000-ampere circuit-breakers will be mounted on the switchboard. These motors, it is stated, will be the largest ever built for this voltage. The Westinghouse Company is also building for the Peoples Power Company, of Moline, Ill., two engine-type generators, to increase that company's present equipment. The machines will be a 1100-kw., two-phase alternator of the revolving field type, operating at 2400 and 4800 volts, and a 600-kw., 600-volt, direct-current machine. An order for three 300-kw. alternating-current generators has also been received by the Westinghouse Company from the Barber Lumber Company, of Boise, Idaho. These machines will generate current at 440 volts, which will be transformed to 23,000 volts for transmission. The necessary transformers, switchboards and lightning arresters are included in the apparatus to be furnished. The Mammoth Copper Mining Company, of Salt Lake City, has just placed an order with the Westinghouse Company for a large addition to their electrical equipment, comprising a total of nearly 800-horse-power in three-phase induction motors of different sizes, together with a motor-generator set, transformers, switchboard and three mining locomotives. Two of the motors have a rated capacity of 200 h.p. each, and five are of 50 h.p. each.

THE ABNER DOBLE COMPANY, San Francisco, reports a substantial and increasing business in tangential water wheels, particularly in large units, the percentage increase in horse-power of wheels sold by the company in 1904 over 1903 being 116 per cent. Among orders recently taken was one for three 7500-h.p. wheels for the Electra plant of the Standard Electric System. One of these will operate under a 1250-ft. head at 400 r.p.m. The other two wheels will be direct-connected to one 4000-kw. generator, forming a double unit for utilizing water from two separate sources under different heads. The design of this unit is an unusual one, in that each wheel has sufficient capacity to drive the generator at full load. One of the wheels will be driven by a 6-inch jet under a head of 1465 feet, the water being taken directly from the main gravity conduit; the other wheel is to be driven by a 7-inch jet under a head of 1250 feet, the source of supply being a large reservoir at the end of the main conduit. A 200-h.p. Doble exciter wheel to operate under a head of 1465 feet at 720 r.p.m. will also be furnished for the Electra plant. Two 800-h.p. main unit wheels and two 40-h.p. exciter wheels have been built for the new Santa Ana No. 2 plant of the Edison Electric Company of Los Angeles, to operate under a head of 305 feet. Two 75-h.p. exciter wheels have been built for the Pike's Peak Hydro-Electric Company of Colorado to operate at a speed of 975 r.p.m. under a head of 2100 feet, the highest in the United States. A 300-h.p. double Doble wheel equipped with two Doble needle regulating nozzles has been ordered by the Hilo Electric Light Company of Hawaii. For the Nevada City plant of the California Gas & Electric Corporation, three 570-h.p. wheels have been supplied to operate under a head of 190 feet. The Bredon Copper Company of Chile has ordered four 340-h.p. wheels for operation under 930 feet head, three for belt drive and one for direct connection to an electric generator.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

WIGGINS.—The Wiggins Electric Light Company has filed articles of incorporation, with a capital stock of $10,000.

BREWTON.—A change is being made in the municipal electric lighting system, the open arc lights being displaced by series enclosed arc lights.

WEST END.—The City Council has granted the Birmingham Railway, Light & Power Company, of Birmingham, a franchise to lay gas mains and construct an electric light system in West End.

GREENVILLE.—The C. C. Henderson Electric Light Company has secured a franchise for an electric light plant. The cost of the plant is estimated at $15,000, and it is to be in operation within four months.

STURDEVANT.—The Tallapoosa Water Power & Electric Company, which was incorporated several months ago by Messrs. Aufeld & Chapman, of Montgomery, is about to begin the erection of a $500,000 plant for developing the water-power of the Tallapoosa River to furnish electric power for manufacturing purposes.

ARKANSAS.

MADILL.—W. F. Porter has been granted a 20-year franchise to establish and maintain an electric light plant here.

PARAGOULD.—The Crystal Ice Company, owner of the electric light plant here, purposes installing a new 250-hp. boiler in its power house.

FAYETTEVILLE.—New machinery has been added to the electric light plant at Fayetteville, which gives the plant a capacity of 5500 incandescent lights.

HARRISBURG.—Reports state that bids will be received until about Apirl 15 for the construction of an electric light plant for this town, the plant to cost about $4000.

TEXARKANA.—Improvements amounting to $50,000 in the electric lighting system are said to be contemplated by the Texarkana Gas & Electric Light Company, of this city.

PRAIRIE GROVE.—C. L. Cummings is said to be interested in establishing an electric light plant here. The project is being discussed, but no definite plans have as yet been formulated.

LITTLE ROCK.—New machinery, consisting of a 350-hp. boiler and a 350-hp. Corliss engine, has been installed recently in the municipal electric light plant. John W. Bleidt is superintendent of the plant.

GAINESVILLE.—C. W. Moore, of this city, and associates have incorporated the Gainesville Gas & Electric Company, with a capital stock of $100,000. The company will establish and operate a gas and electric light plant.

CALIFORNIA.

CEDARVILLE.—H. Hawkins is said to be interested in the construction of an electric light plant for this place.

OXNARD.—Local reports state that plans are being discussed for the establishing of a new electric light and power plant which will cost about $100,000.

MAYFIELD.—A company of local capitalists has been organized for the purpose of establishing an electric lighting plant to furnish light and power for the town and vicinity.

BODIE.—The Walker River Electric Company has been incorporated by Arthur Cohn, Charles Day, Will Reading and others. The capital stock of the company is stated to be $20,000.

SANTA MONICA.—The Citizens Gas & Electric Company has filed articles of incorporation with the Secretary of State, with a capital of $60,000. F. E. Bundy is president and C. C. Rathbone is also among the incorporators.

SAN FRANCISCO.—Articles of incorporation have been filed by J. A. Kretschmar and J. Alexander, of this city, and P. C. Medcraft and L. A. Redman, of Alameda, for the Oro Water, Light & Power Company, capitalized at $3,500,000.

BAKERSFIELD.—The Trustees are advertising for sealed proposals for furnishing all material and appliances and installing a complete electric fire-alarm system in that city, according to plans and specifications on file. A. T. Lightner is city clerk.

FAIR OAKS.—A meeting of the citizens of this town and Menlo Park was held recently at the latter place for the purpose of devising means to establish an electric lighting system. John McBain and John H. O'Keefe were appointed a committee to investigate the feasibility of the plan.

LAKEPORT.—It is reported that James K. Burch has applied for a franchise to erect poles and suspend wires on the highways, streets and alleys of this town for the purpose of transmitting light, power and heat. Bids for the franchise will be received April 3 by H. V. Keeling, Clerk.

SALINAS.—The new machinery for the Monterey County Gas & Electric Company's plant at this point is expected to arrive in the near future. The equipment will consist of two 250-h.p. boilers and two 200-h.p. Corliss engines; also two 150-kw. National alternators of the revolving-field type.

SAN FRANCISCO.—The Battle Creek Power Company has been incorporated, with a capital of $1,000,000, by Henry Ward Brown and Walter E. Carre, of Colma; Harold L. Wright, of this city, Dudley Bates and others. Plans are under way for the construction of a power plant at Gridley, this State.

OROVILLE.—E. W. Sutcliffe, representing the Northern California Electric Railway & Navigation Company, has been granted a two-year franchise for a pole line to transmit electricity over the streets and highways of Butte County. The purpose of this two-year franchise is to allow the company to construct its line immediately.

SAN FRANCISCO.—A party of Denver capitalists who are interested with Lawrence Phipps on the Bishop Creek project to supply Tonopah and Goldfield, Nev., with electric power, have been in San Francisco completing arrangements for the carrying out of the enterprise. Among the party were Rodney Curtis, of Denver; Samuel Woods and F. J. Campbell. The proposed plans of the company include the establishment of a generating plant at Bishop Creek in California. From the natural flow of the creek the company expects to develop 400 horse-power and will increase the capacity to 20,000 by the construction of three small dams along the stream at a cost of $100,000.

ELMHURST.—Work is being rushed on the 500-h.p. motor-generator for the new electric plant being installed here. It will be necessary to run a wire from the Southern Pacific tracks to the power house, as the line from the Amador County source is not yet completed. A switch-house must be erected also. The Standard Electric Company, it is said, will have control of the power and will sell it to the Oakland Traction Consolidated Company. The old plant will be shut down, but is to be held in readiness for emergencies. There will be also a connection made with the De Sabla power house, near Chico, belonging to the Bay Counties Company, which will furnish electricity if needed. Water-power will be used in each of the primary power houses to generate alternating current at 50,000 volts. This will be transmitted to the Elmhurst plant, where direct current is also generated for the cars on the Haywards line of the Oakland Traction Consolidated Company.

UKIAH.—The Eel River Power & Irrigation Company has been incorporated recently with a capital stock of $500,000. The directors are: F. D. Madison, of San Francisco; W. W. Van Arsdale, H. B. Muir, R. E. Donohue and W. P. Thomas. Work will be commenced on the plant immediately. It will be located in Potter Valley, where a tunnel one and one-half miles long will be dug through the mountain, where it will have a fall of 470 feet to the wheels that will run the electric generators. The water will be taken from Eel River about 20 miles from this city and will be used to irrigate Potter and Ukiah Valleys after it has been utilized for power purposes. The plant will have an initial capacity of 500 horse-power, but the tunnel and ditches will be large enough to carry sufficient water to operate a 2500-h.p. plant. The city of Ukiah is particularly interested in this enterprise, and overtures for the purchase of the power and light are in progress. At the last meeting of the Board of Trustees a motion was made and unanimously carried, on behalf of the city, to make the new company an offer to enter into a contract with the company to purchase for a term of fifteen years, at $4.00 per horse-power, electric current to be delivered at the switchboard; the city to take 250 horse-power at first, with the absolute privilege of increasing the amount of current whenever the city sees fit, the limit being 500 horse-power. The city is to have the exclusive sale of electricity for light and power within a radius of three miles square, with the court house as a center. This will give an area of one and one-half miles each way from the court house, excepting, however, the new company shall have the right to sell power to the water works for pumping water for municipal purposes, or do it themselves, if they so desire. The city also reserves the right to sell light and power to Vichy Springs and the asylum. The plant is expected to be completed and in operation on or before October, 1906.

COLORADO.

MONTROSE.—The Town Council has granted the Montrose Light & Power Company a ten-year franchise.

FLORENCE.—The Arkansas Valley Electric Company of this city has been granted a franchise by the City Council, granting it the privilege to erect poles and string wires within the town limits.

SILVERTON.—The city authorities have arranged to install at the municipal electric light plant another 110-kw. unit and a new switchboard and the system will be changed to three-phase. H. S. Sherman is manager.

DILLON.—W. H. Foster, who last fall purchased the old Ora Grande placer workings a half mile north of Dillon, has interested New York capital and will shortly begin the construction of a large electric power plant on the property. The ditch from which the water power will be obtained is nine miles long.

AGUILAR.—At a mass meeting held recently a stock company was formed by A. R. Lindsey, Morris Pitti, H. Pinamonti, Dr. A. B. Harbison, and others, for the purpose of installing an electric plant and lighting system at a cost of $10,000. This is the first step toward municipal ownership, the city having an option on the purchase of the plant at the end of five years.

BOULDER.—The Boulder Electric Light & Power Company has made application to the Council for a new franchise. The old one does not expire for some time, but the company desires additional privileges, among them the right to haul freight through the streets of the city, and therefore asks for a new franchise. It will be voted upon by the people at a regular election.

EMPIRE.—W. P. Clough, of Denver, president of the Clear Creek County Power & Irrigation Company, writes that it is proposed to construct a water-power plant for the generation of electricity for mining and irrigation purposes. The plant, it is estimated, will cost about $75,000 and the contracts will probably be let about May 1. H. R. Oliver, of Georgetown, Colo., is the engineer in charge of the work.

CONNECTICUT.

WALLINGFORD.—Arrangements are being made at the municipal electric plant for the development of about 200 kilowatts by water power in order to supply a day service. This will be in addition to the present steam plant. A. L. Pierce is manager.

TORRINGTON.—At the annual meeting of the Torrington Electric Light Company held recently the following officers were elected: President, George D. Workman; treasurer, Frank M. Travis; secretary, Frederick F. Fuessenich, who together with Henry J. Hendy, Gideon H. Welch, James A. Doughty and John Workman constitute the board of directors.

GLASTONBURY.—James S. Williams, president of the Glastonbury Power Company, writes that engineers are now at work on specifications for the work in connection with the construction of its new power house and dam. The work will probably cost in the neighborhood of $175,000. No contract has been let as yet. Lewis W. Ripley is secretary of the company.

STAFFORD SPRINGS.—Arrangements have been made for the continued operation of the Stafford Springs Electric Light & Gas Company, and the announced intention to close down the plant has been reconsidered. Mr. Warner, of Bridgeport, has been appointed receiver for the company with authority to continue the operation of the plant. A re-organization of the company will probably be effected.

EAST HADDAM.—Ransom & Hoadley, of Providence, R. I., are said to have bought the entire rights of the Salmon River Power Company, which is controlled by the Connecticut River Banking Company, of Hartford, and expects to enlarge the plant at Leedsville, spending about $300,000 in improvements. The Salmon River Power Company has furnished power for the East Haddam Electric Light Company at Leedsville.

DELAWARE.

SEAFORD.—At a recent election the citizens voted in favor of the town owning its own electric light plant.

GEORGETOWN.—The Council has granted to the Georgetown Electric Light Company a franchise and a contract to light the city. There will be 100 lights installed. The company consists of George W. Goodley, W. R. Goodley and W. J. Peal, of Wilmington. The company has already awarded the contracts, and the work of installing the plant will begin at once.

DISTRICT OF COLUMBIA.

WASHINGTON.—The last legislation necessary to secure the placing underground of all telegraph, telephone, electric lighting and other overhead wires in the District of Columbia was enacted by the last Congress and signed by the President, March 3. Commissioner McFarland, who has been especially active in his efforts to secure the removal of all poles and overhead wires ever since he became Commissioner, estimates that within five years the people of the District can reasonably expect that all overhead wires within the city limits will be taken down and placed underground.

FLORIDA.

ST. AUGUSTINE.—F. N. Holmes, it is said, contemplates the construction of an electric light plant here.

GEORGIA.

CEDARTOWN.—A new steam power plant is being installed by the Water & Light Department of the town.

VALDOSTA.—A. W. Vamedoe, City Clerk, writes that the Mayor and Council are investigating the cost of an electric light plant.

COVINGTON.—The City Council contemplates re-establishing the city electric light plant, which was recently destroyed by an explosion.

JESUP.—The manager of the Jesup Light & Ice Company states that the company expects to increase the city lights about one-third very shortly.

TIFTON.—The Tifton Ice & Power Company recently installed a new engine and dynamo in its power plant. S. M. Roberts is manager of the company.

WASHINGTON.—Thomas Ludlow, superintendent of the municipal lighting plant, states that it is proposed to install a 150-kw. alternating-current generator.

FORT VALLEY.—The citizens have voted affirmatively on the proposed issuance of $12,000 bonds to establish an electric light plant and improve the water works.

CARTERSVILLE.—A committee has been appointed by the City Council, with W. H. Milner as chairman, to investigate the question of constructing an electric light plant and sewerage system.

ALBANY.—The contract for the erection of the dam and power house of the Albany Power & Manufacturing Company has been awarded to B. H. Hardaway, of Columbus. The terms of the contract call for the completion of the dam and power house by the first of September. The work involves an expenditure of about $100,000. Construction will begin at once.

SAVANNAH.—Articles of incorporation have been granted to the Savannah Lighting Company. The incorporators are John J. Cummings, Lawrence McNeil, John H. Estill, Joseph D. Weed, Henry Blun, Samuel Meinhard, Willis A. Burney, Jr., John Flannery, Samuel B. Adams, Pleasant A. Stovall, J. H. H. Entelman, B. H. Levy, George W. Tiedeman and Leopold Adler. The company proposes to carry on a general electric lighting and power business, the power being supplied from the Savannah Lumber Company's plant, on whose property the electric plant will be erected. The capital stock of the company is $50,000, they having the privilege of increasing it to $500,000.

CANTON.—A. J. Warner, formerly of Ohio, but now of Gainesville, and his associates, have been granted a charter by the Cherokee superior court incorporating the Etowah Power Company, with a capital of $10,000, with the privilege to increase to $1,000,000. The company expects to build a dam 600 feet long and 30 feet high across the Etowah River, about four miles below Canton, which probably will be completed during the year. The company organized by the election of A. J. Warner, president; E. P. Kirby, vice-president; W. K. Slack, secretary and treasurer; P. P. DuPre, of Canton, general counsel; W. A. Carlisle, chief engineer, and F. P. Catchings, electrical engineer. Board of directors: A. J. Warner, W. A. Carlisle, W. F. Huntley, E. P. Kirby, all of Gainesville; C. M. Merrick, of Pennsylvania, and P. P. DuPre and F. P. Burtz, both of Canton. The company has already acquired some property along the Etowah River.

HAWAII.

HONOLULU.—The Kauai Electric Company has been incorporated by D. P. R. Isenberg, William A. Kinney, Francis M. Swanzy, and others. The company is capitalized at $300,000 and will supply power for various purposes.

IDAHO.

HAILEY.—The owners of the Hailey Electric Supply Company propose building another plant at once.

SHOSHONE FALLS.—The electrical equipment for its plant has been ordered by the Shoshone Falls Power Company.

COEUR D'ALENE.—The Spokane Traction Company, of Spokane, Wash., will erect a $700,000 power plant at this point. Jay P. Graves is president.

WALLACE.—The Wallace Light & Power Company, of which D. C. McKissick is superintendent, will probably install some new machinery in its plant this summer and will also put in a steam plant.

MOUNTAINHOME.—A site has been selected at Crane Falls on the Snake River for the establishment of the proposed power plant of the Mountainhome Light & Transit Company, of this city. The construction of an electric road between here and the Snake River Valley is among the projects of the company.

BOISE.—Work is progressing rapidly on the Oxbow Tunnel on the Payette River, where later a large power plant is to be installed. The cost of the tunnel when completed is estimated at $125,000, and the total cost of the plant when thoroughly equipped and prepared to supply electrical energy to Boise and other cities will be about $1,500,000. The machinery for the plant will be on the ground in August, it is said, although it will be some months later before the plant wil be ready for operation.

ILLINOIS.

LEBANON.—It is proposed to install at the city light plant a new dynamo, engine and smoke stack.

STONINGTON.—L. D. Hewitt is said to be interested in the construction of an electric light plant here.

VERMONT.—The city expects soon to purchase a new dynamo for the electric light plant. Mr. E. L. Durrell is manager of the plant.

MORRISONVILLE.—The Morrisonville Electric Company is installing a central station steam heating plant in connection with its lighting plant.

MOWEAQUA.—The Moweaqua Electric Company, of which W. N. McKee is manager, proposes installing a steam heating plant (exhaust).

CHARLESTON.—The Charleston Illuminating Company has filed articles of incorporation. George M. Sefton, Flavion Mason, and others, are among the incorporators.

PANA.—Eastern capitalists are said to have been negotiating for the purchase of the electric plant here, and it is probable that the deal will be closed shortly.

PAXTON.—The Paxton Electric Company states that it is replacing arc lights with multiple-glower Nernst lamps having 2, 3 and 4 glowers, and finds them most satisfactory.

CHICAGO.—The Calumet Lighting Company, formerly the Calumet Gas & Electric Company, has conveyed its property and plant to the North Shore Electric Company, it is said.

MORTON.—Beyer Brothers, owners of the electric light plant, write that they expect to increase their power circuit to 150 kilowatts, and will install a 200-h.p. engine for the purpose.

PERU.—A new 150-h.p. boiler is to be installed in the municipal electric light plant, and about 7000 feet of 750,000 c. m. of stranded bare copper cable will be put in this summer.

BLOOMINGTON.—The City Council has granted to C. A. Griffin, S. R. White and P. R. Longworth a franchise to manufacture and distribute steam and electricity for heating, lighting and power purposes.

LA GRANGE.—By a vote of five to one the Village Board decided to sell the village water-

works and lighting plant to the Chicago Edison Company. None of the details of the transaction have as yet been made public.

SOUTH ELGIN.—V. W. Panton, owner of the local electric light plant, states that they have water power running to waste, and that extensions will be made to the present plant in order to utilize a portion or all of this.

DECATUR.—The Consumers' Gas & Electric Company has been incorporated with a capital of $50,000 to manufacture light, heat and power. Among the incorporators are W. M. Bering, Charles S. Needham and James M. Gray.

EAST ST. LOUIS.—Mayor Cook has appointed C. B. Goedde, Jacob Gohn and L. Smith a committee to visit other cities to ascertain the cost of electric lighting and of municipal ownership of electric plants. W. J. Crocker is city engineer.

MORRIS.—The Fields Electric Light Company has in contemplation the following improvements: 5 miles of line, a 250-h.p. compound engine, a 200-kw. alternator, one condenser, a pump, day power circuit and all-night service. Mr. F. B. Handwerk is manager of the company.

KIRKWOOD.—Plans are being considered for rather extensive improvements to the plant of the Kirkwood Electric Company, of which J. F. White is manager. A steam heating and pumping plant for the city will be added and the electric lighting circuits will be extended to two neighboring towns.

ROCKFORD.—With the opening of spring the Rockford Edison Company contemplates a large number of extensions. Besides the purchase of additional machinery, two boilers of 500 horsepower each will be placed in position soon. It is estimated that the cost of the improvements will amount to about $15,000.

EDWARDSVILLE.—The McKinley Syndicate, controlling and operating the interurban lines of the Illinois Central Traction Company, the St. Louis and Springfield Electric Railway Company and the St. Louis & Northeastern Railway Company, has purchased the power plant of the Edwardsville Electric Light & Power Company.

KEWANEE.—At the annual meeting of the Kewanee Light & Power Company, Xenophon Caverno, James K. Blish and B. C. Parkinson were elected directors for the coming year. The directors chose officers as follows: President and general manager, Xenophon Caverno; vice-president, James K. Blish; secretary, B. C. Parkinson.

DANVILLE.—Press reports state that the Danville St. Railway & Light Company is preparing to expend $50,000 in improving its lighting system here. Mr. W. B. McKinley, who is president of the company, is also contemplating improving his plant at Decatur, the improvements to include the installation of new boilers and the laying of new gas mains.

TAYLORVILLE.—The Taylorville Gas Company has bought the stock of the Taylorville Electric Company and the corporate name of the new concern will be the Taylorville Gas & Electric Company, with a capital stock of $127,500. For the present, at least, J. N. C. Shumway, who has been the manager of the Taylorville Electric Company, will be manager for the new corporation.

MOLINE.—The Westinghouse Electric & Manufacturing Company has been awarded a contract by the People's Power Company for a 1100-kw. two-phase alternator, operating at 2400 and 4800 volts and a 600-kw. 600-volt direct-current machine. The power company has also placed a contract for a 24x50x48-in. horizontal compound Reynolds-Corliss engine with the Allis-Chalmers Company.

ELGIN.—The town has leased its electric plant to the Elgin, Aurora & Southern Traction Company, from which it will purchase current. It is said that the latter company is preparing to furnish lighting current to several of the towns along its line. Motor-generator sets, together with the necessary transformers and switching apparatus, are being installed in some of the substations.

ZION CITY.—The Zion Building & Manufacturing Association contemplates installing a 500-h.p. engine direct-connected to a 300-kw. alternating-current three-phase 60-cycle generator, a motor-generator set, one 100-kw. three-phase 60-cycle machine, a switchboard of eleven panels, two 250-h.p. boilers of the Cahall type, and a series alternating street lighting system. Burton C. Dennis is manager of the lighting plant.

FREEPORT.—A. P. Goddard, formerly president of the Freeport Railway, Light & Power Company and a member of the National Electric Light Association, died at his home in this city recently at the age of 72. He was born in Franklin County, N. Y., but his family removed to Freeport when he was two years old. Mr. Goddard was prominently identified with the development of the town, having served as alderman, mayor and member of the board of supervisors. He also served in the Civil War as first lieutenant in the Illinois Volunteer Infantry, and was brevetted a captain for honorable service.

INDIANA.

HOPE.—George S. Cook has secured a franchise for the establishment of an electric light plant at Hope.

JEFFERSONVILLE.—James H. Duffy is promoting a project to establish an incandescent electric light service in Jeffersonville.

JASPER.—The Jasper Electric Light Company is engaged in rebuilding some of the lines and has recently installed a new alternating-current dynamo.

OOLITIC.—The Town Board has decided to construct a water works and electric light plant at an estimated cost of $23,000. George C. Morgan, Chicago, is the engineer.

HAMMOND.—The South Shore Electric Company has ordered from the Allis-Chalmers Company one heavy-duty 24x48-in. engine for direct-connection to a 425-kw. alternating-current Bullock generator.

INDIANAPOLIS.—The F. H. Cheyne Electric Company, of this city, has filed articles of incorporation, with a capital stock of $20,000. Frederick H. Cheyne and Roland R. Ferry are among the incorporators.

WARSAW.—The Winona Electric Light & Water Company has purchased the water and electric light plant at this place. It is proposed to erect a standpipe 150 feet high and 18 feet in diameter and make improvements to the electric light plant.

RIDGEVILLE.—Articles of incorporation have been filed by Joseph, C. L. and Arthur Lay for the Ridgeville Electric Light & Power Company, having a capital stock of $10,000. The company will construct and operate a light, heat and water plant.

MUNCIE.—W. F. Warren, superintendent of the city electric light plant, writes that it is proposed to construct a new central lighting plant at once. Gas or oil engines and storage batteries will furnish the power, and it is estimated that the plant wil cost $120,000.

BREMEN.—The superintendent of the municipal electric light plant writes that it is proposed to install a 250-h.p. Harrisburg Fleming engine about the first of April. New fronts for the boilers will be provided and a new heater and boiler feed pump will be put in.

TERRE HAUTE.—An ordinance has passed the City Council appropriating $1200 with which to employ an engineer to prepare plans and specifications for the proposed municipal lighting plant. The McCulloch Company, of St. Louis, has been selected to procure data and draw up the plans.

LAFAYETTE.—Isham Randolph, engineer of the sanitary district of Chicago, in his report to the business men of Lafayette who are interested in the feasibility of building a dam across Wabash River for the generation of power, estimates the total cost of the dam, hydraulic and electrical equipment at $248,000.

BICKNELL.—The Bicknell Light & Power Company, with a capital of $10,000, has been incorporated, with the following board of directors: A. L. Brocksmith, B. P. Barnes, J. G. Welton, J. H. Welton and E. G. Barnes. The County Commissioners have granted the company a franchise to furnish light in Bicknell.

ODON.—The Odon Light & Power Company is preparing plans for the construction of a new power house which will be equipped with new engine, boilers and dynamos. The company is also arranging to install a water works system, which will be completed in about eighteen months. C. N. McNeely is manager of the company.

BRAZIL.—The Brazil Electric Company has secured a site upon which to erect its new power plant, and the power house is now in course of construction. When this is completed the company will be in position to supply commercial service to the entire city. The work of extending the city lines will begin some time during this month or the next. The new machinery and equipment has been nearly all purchased or is under contract.

NEW ALBANY.—The Louisville & Southern Indiana Traction Company recently installed in the power house of the United Gas & Electric Company, of this city, two 500-kw. three-phase steam turbine units operated at 4500 volts. One of them runs the arc lights at Jeffersonville, five miles distant, and the current from the other one is transformed by a booster and operates the street railway at Jeffersonville. Both three and four-wire distribution are used, the former for lighting and the latter for the street railway.

NOBLESVILLE.—George W. Heinzmann & Company have been awarded a ten-year contract for lighting the city. The company is required to furnish 80 arc lights at $70 a light per year, and ten cents per thousand watts will be charged for incandescent lights. The old electric light company, which now has the contract, and the Noblesville Hydraulic Company have been consolidated with the new concern. The large dam across White River, north of the city, which the Hydraulic Company began two years ago, but which was not completed on account of an injunction, will be completed. The old company's present steam plant will be remodeled and held in reserve in event of the water power not being available at all times. The two plants, when in operation, will represent an investment of $150,000.

INDIAN TERRITORY.

TULSA.—The People's Oil & Gas Company has been granted a franchise to wire the city for electricity and pipe it for natural gas.

FORT GIBSON.—D. W. Bolich is making surveys for a proposed $1,000,000 hydro-electric plant, to be built on the Grand River near this point.

MADILL.—F. W. Porter, of Whitehall, Wis., has been granted the franchise for which he applied recently to construct an electric light plant in Madill.

SOUTH McALESTER.—Articles of incorporation have been filed with the Secretary of State by the Choctaw Electric Company. The company is capitalized at $150,000, with A. E. Pierce as president, and will succeed the South McAlester Electric Light & Power Company. M. M. Lindley is secretary, and A. W. Thomas, treasurer.

IOWA.

ATLANTIC.—The city authorities anticipate changing the entire system from direct to alternating current.

SIBLEY.—The Sioux City Interstate Supply Company, it is said, contemplates installing a local electric light system.

MANSON.—William Folkers, superintendent of the Manson Electric Light Company, writes that the plant will require a new engine before very long.

NORTHWOOD.—L. F. Madson, owner of the electric light plant here, contemplates installing an engine, two generators and new switchboard apparatus.

THIBODAUX.—Reports state that a storage battery system is to be installed at the municipal lighting plant, for the purpose of supplying fans, motors, etc.

KNOXVILLE.—The Knoxville Electric Company is installing a heating plant and will add an alternating-current circuit for the supply of outlying districts.

MAQUOKETA.—M. S. Dunn, H. W. Kruse, and other, have filed articles of incorporation for the Maquoketa Light & Heat Company, with a capital stock of $25,000.

RED OAK.—The Red Oak Electric Company reports that it is about to install two new 150-h.p.

boilers and one 600-h.p. horizontal Camp engine direct-connected to a 500-kw generator.

INDIANOLA.—J. M. Harlan, president of the Public Water Power & Heating Vompany, writes that about $25,000 will be expended in improvements. The company will install Scaife filters and purchase new pumps.

CENTERVILLE.—Richard Slattery, representing the Mutual Electric Light Company, has petitioned for a franchise to operate an electric light plant. The question will be submitted to the people at the spring election.

VALLEY JUNCTION.—The Valley Junction electric light and water plant, which has been in the hands of eastern capitalists, has been sold to four local parties, who will incorporate under the laws of Iowa and form a stock company. The title will be transferred to John Fisher, A. H. Dyke, J. T. and Charles Ashworth.

CORNING.—C. K. Munns, proprietor of the Munns Electric Company, writes that the plant of the Corning Electric Company, which has been in his hands as receiver for the past year, was bought by him at trustees sale in December last and the name changed as above. He expects to overhaul the entire outside construction this spring.

DECORAH.—The Decorah Electric Light Company contemplates developing a water power and transmission line to operate this plant and one at Waukon, in all eighteen miles of line. There will be required, besides a dam, two 200 to 250-h.p. wheels, two 128-kw. 6600-volt three-phase 60-cycle generators, about 250 kilowatts in transformers, and the usual accessories for such an equipment. W. H. Burtis is president of the company.

KANSAS.

WICHITA.—The Citizens' Light, Heat & Power Company expects to erect a new plant.

WICHITA.—The United Electric Company has been incorporated in this city with a capital of $10,000.

WICHITA.—The Wichita Railroad & Light Company reports that it is installing another alternator in its power plant.

LEAVENWORTH.—Local capitalists have completed arrangements for the building of a $5000 electric light plant at Onaga.

JEWELL CITY.—A. G. Blankenship writes that bids will be received May 15 for constructing an electric light plant to cost $2000.

LEAVENWORTH.—The United Gas & Electric Company, of which M. E. Springer is manager, recently installed in its power plant two new 72x18 horizontal boilers.

HIAWATHA.—The superintendent of the city electric light plant writes that the entire circuit is being reconstructed and the old open arc lights replaced with enclosed arc lights.

WICHITA.—The Merchants' Heating & Lighting Company is making arrangements for the construction of an electric light and heating plant to cost about $300,000. W. H. Scott, Marquette Building, Chicago, is the engineer.

ANTHONY.—W. K. Palmer, 718 Dwight Building, Kansas City, Mo., has been engaged as engineer for the city in connection with the construction of a municipal electric light plant. Plans and specifications are now being prepared.

JUNCTION CITY.—Reports state that the Republican River Hydraulic Power Company is preparing to construct a dam across the river at this point, where it expects to develop about 1200 horse-power by means of turbine water wheels for the generation of electricity.

LAWRENCE.—A movement is on foot here for the consolidation of the gas and electric light plants of the city. About $200,000 will be expended immediately, according to the report. F. A. Sharpe is said to be the chief promoter of the enterprise. It is probable that the dam across the Kaw River will be utilized for power purposes if the reorganization is consummated.

KENTUCKY.

HICKMAN.—Reports are to the effect that the electric light plant here was recently destroyed by fire, but none of the particulars have been learned.

NICHOLASVILLE.—C. S. Evans, manager of the municipal electric lighting plant, states that an alternating-current generator has been recently purchased and installed in the plant.

MT. STERLING.—The Mt. Sterling Electric Light & Water Works Company recently purchased a deep well pump and a 6x4x6 duplex boiler pump. Its engine equipment has also been thoroughly overhauled.

HARTFORD.—Ike C. Adair has been elected president and J. D. Cooper, vice-president and general manager of the Kentucky Light & Power Company, recently formed to install an electric light plant at Hartford.

LOUISVILLE.—At the annual meeting of the Evansville Gas & Electric Company the following officers were elected: President, E. B. Lewis, of Chicago; vice-president, F. J. Reitz; secretary, W. B. McDonald; treasurer and auditor, James H. Foster.

LAWRENCEBURG.—Organization of the Lawrenceburg Electric Light Company has been completed by the election of officers as follows: President, J. M. Johnson; vice-president, E. W. Ripy; secretary, C. A. Leathers; treasurer, R. S. Collins. An electric light plant will be installed by the company at once at a cost of about $12,000.

CARLISLE.—A recent fire entirely destroyed the plant of the Citizens' Electric Light Company, entailing a loss of $10,000, upon which there was only $2000 insurance. The destruction of the plant leaves the city in darkness until temporary arrangements can be made to supply illumination. The plant will be restored at once. C. F. Holderman is superintendent.

LOUISIANA.

NATCHITOCHES.—J. R. Carroll, superintendent of the Natchitoches Electric Light & Water Works Company, reports that it is expected to install a new engine and dynamo shortly.

ABBEVILLE.—George W. Summers, secretary of Council, states that it is proposed to construct water works, electric light and sewerage systems, and the question of issuing $45,000 worth of bonds will be submitted to a vote of the people.

LAKE CHARLES.—The discussion in reference to the construction of a municipal electric light plant has culminated in completed plans and specifications for a plant to cost about $70,000. The matter is now in the hands of the City Attorney, who will probably get it in shape very shortly.

ALGIERS.—R. S. Stearns, general manager of the Algiers Water Works & Electric Light Company, makes the statement that it is proposed to extend the system to Gretna and furnish that town with light. It is also proposed to construct ten miles of electric railway between Algiers and Gretna, installing a complete three-phase system.

SHREVEPORT.—As previously announced, bids are invited for the electric lighting of the city for periods of five and ten years, the number of lights to be not less than 150 and subject to increase. Arc lights are to be not less than 2000 candle-power. Bids must specify the charge for arc lights and also for incandescent lights and specify the maximum charge to be made to private consumers of arc and incandescent lights. The arc lights for street lighting shall burn every night. All bids must be in the hands of the City Comptroller by 6 p. m., April 11.

MAINE.

AUGUSTA.—The recent incorporation is reported of the Home Light & Heat Company, with a capital of $300,000. M. H. Simmons is president, and E. F. Whittum, secretary.

BAR HARBOR.—Recent reports are to the effect that New York and Boston capitalists have purchased the stock of the Bar Harbor & Union River Water Power Company and will construct a dam 60 feet high on Union River near Ellsworth.

PORTLAND.—The Consolidated Electric Light Company of Maine proposes adding to its plant the following equipment: A 360-kw. three-phase alternating-current dynamo, three 320-kw. 110-volt direct-current dynamos, one 1000-h.p. heater, one 1500-h.p. condenser and the necessary piping. G. E. Raymond, of Portland, is secretary.

MARYLAND.

LUTHERVILLE.—This town is now lighted by electricity furnished by the Mount Washington Electric Light & Power Company.

SALISBURY.—The Salisbury Light, Heat & Power Company has just completed and moved into its new fireproof power station. A new boiler house is now to be erected and the lines will be thoroughly overhauled this spring. Ralph B. Rhodes is manager of the company.

BALTIMORE.—The Board of Awards is considering the bids received on the 8th of March for the street electric arc light contract. Superintendent of Lamps and Lighting Robert J. McCuen, is also in receipt of a proposition from a New York engineering company to install a municipal light plant and citing the cost of the plant and the cost per light after the plant has been established. The plant suggested would consist of a 2000-h.p. double-unit gas producer, capable of operating many thousands of lights. The producers may be operated by coal, coke, charcoal, wood or peat as fuel. In the engine-room would be three 600-kw. generators. The approximate cost of the plant is estimated at $325,000, including building, piping, foundations and all necessary machinery and electrical equipment. The cost of producing the light is also gone into thoroughly, it being estimated at less than $25 for 3000 arc lights per year of 4000 hours. In case none of the bids is low enough to be satisfactory to the board, the proposition of the New York company will be taken up and thoroughly discussed.

MASSACHUSETTS.

WESTON.—The Weston Electric Light Company is planning to duplicate its boiler equipment.

MELROSE.—At a meeting of the Aldermen an order was passed authorizing the Mayor to make a contract with the Malden Electric Company for lighting the city for one year from February 1 at a cost of $12,256.

WORCESTER.—Reports state that C. T. Sherer and George Crompton are interested in the construction of an electric plant to supply light and power for the buildings in the square bounded by Main, Front, Commercial and Mechanic Streets, this city.

MICHIGAN.

BOYNE CITY.—The Boyne City Electric Company will shortly operate its plant by water-power.

ALPENA.—Bids are being considered for the construction of water works and an electric light plant.

BAY CITY.—The Council has granted to West Bay City a franchise to do commercial lighting in this city.

HOPKINS STATION.—W. F. Nicoli is said to be interested in the construction of an electric light plant here.

EVERT.—The advisability of installing in the municipal lighting plant a storage battery system is under discussion.

ST. CLAIR.—This city contemplates installing new boilers and pumps at the electric light and water works. Walter Ash is chief electrician.

BLISSFIELD.—The equipment of the city electric light plant is to be increased by the addition of a feed-water heater and new transformers.

BIG RAPIDS.—The W. E. Donley Electric Light & Power Company thinks it may be necessary to replace its present equipment with larger machines.

SHELBY.—It is proposed to install at the municipal electric light plant new engines and an alternating-current generator. H. L. Andrus is superintendent.

SAULTE STE. MARIE.—It is reported that about $1,000,000 will be expended in the near future by the Michigan Lake Superior Power Company for improvements.

GRAND RAPIDS.—The usual annual extensions are being made to the municipal lighting circuits, the new circuits, amounting to about 35,000 feet, being placed underground.

CHEBOYGAN.—The Cheboygan Electric Light & Power Company has recently installed two 500-kw. 11,500-volt 60-cycle alternating-current generators operating at 200 r.p.m. and direct-connected to Leffel turbines.

HART.—It is expected that a complete change will be made in the street lighting system during the year. The Fort Wayne open arc lights are

now used, but will probably be displaced by enclosed arcs of the same kind.

DETROIT.—A bill authorizing the issue of $150,000 improvement bonds for the Detroit Municipal Lighting Commission has been approved by Mayor Codd and sent to Lansing to be taken in hand by the Wayne County delegation.

SPRINGWELLS.—The town has accepted the bond of John A. Russell for $3000. Mr. Russell has a franchise for commercial lighting within the township, under the conditions of which the plant must be in operation by September 1.

CHARLEVOIX.—Plans are under way to operate the city electric light plant by means of current generated by water power at Bellerin and transmitted from there, a distance of 28 miles. A day circuit with a capacity of 500 horse-power will be added this year.

MARSHALL.—The superintendent of the electric light and water works writes that they have taken out the direct-current arc lights and installed a complete Westinghouse alternating-current street lighting system, together with an alternating-current generator for supplying the same.

ZEELAND.—It is proposed to install at the village electric light plant, some time during the spring or summer, a 25-kw. 235-volt direct-connected unit which will take care of the small or light loads. An all-night service will be inaugurated also as soon as this set has been put in.

ALBION.—The city has just turned down a 30-year electric light franchise proposed by the Jackson-Battle Creek Traction Company. Fault is also found with the present service from the gas plant which is owned by Grand Rapids parties and operated under a 30-year franchise granted in 1895.

ROMEO.—The village authorities are arranging to install a 1500-light alternator and 45 alternating-current arc lamps in place of one 50-light arc machine and direct-current series lamps. It is possible that a 60-h.p. engine will be purchased to operate the present alternator and a 125-h.p. engine for the new 1500-light machine.

SAULT STE. MARIE.—According to recent reports the Edison Sault Electric Company is prepared to let contracts at once for the construction of a new power plant here. About 3000 horse-power will be developed at first and the capacity of the plant will be increased as fast as the demand warrants. During the coming summer the company expects to invest about $120,000 in the undertaking. Alexander Dow, of Detroit, is said to be at the head of the enterprise.

PONTIAC.—The Clinton River Power Company is to be organized as soon as a franchise can be secured from the city. The promoters now control six miles of the Clinton River and are in possession of the necessary funds to push the scheme as soon as a franchise is granted. The company will be incorporated for $100,000. Water wheels, alternating-current dynamos and other equipment will be required. Seeley & Son, of Amy, Mich., are interested in the project.

DOWAGIAC.—The question of making necessary changes and improvements to the city electric light plants will be submitted to the people at the annual spring election. These will include the rebuilding of the pole line and rewiring the system, which will require about twenty miles of No. 6 W. P. wire, a 75-kw. regulator at the station, a few alternating-current series arc lamps, 150 incandescent series lamps, shunts, new 35-ft. poles, etc. D. E. Connine is superintendent of the plant.

DETROIT.—The Detroit Commercial Electric Light Company has been organized and an application made for a franchise. The promoters agree to start work within sixty days after the granting of the franchise. The concern is capitalized at $1,000,000, and the following-named parties constitute the board of directors: W. E. Fenwick, James Kennedy, Morris M. Green, Charles F. Medbury, James Hanley and H. W. Wells. Options have been secured on river front property 9000 feet east of the present plant of the Solvay Process Company at Delray. The generators will be driven by gas engines supplied from the Solvay Company's plant.

MINNESOTA.

WACONIA.—The citizens have voted for a bond issue of $4500 for the erection of a lighting plant.

WHITE BEAR.—The White Bear Electric Company will construct an underground lighting system at Manitou Island, which is distant one mile.

AUSTIN.—An alternating-current generator, having a capacity of 500 kilowatts, has been recently installed in the Austin electric light plant.

FOLEY.—Daniel Stimler, of Minneapolis, is said to have petitioned the Village Council for a 20-year franchise for an electric light plant here.

ST. PAUL.—The Berggren Electric Company has been incorporated with a capital of $50,000. E. F. and Godfrey Berggren are the principal incorporators.

WADENA.—The superintendent of the water and light plant is reported to have recommended a heat distributing system in order to utilize the waste steam from the plant.

SOUTH STILLWATER.—Fire recently partially destroyed the local electric light plant at this place, entailing a loss of about $5000. The plant will be reconstructed at once.

MINNEAPOLIS.—The International Lighting Company has filed articles of incorporation with a capital of $2000. C. W. and George M. Furbar, of this city, are the incorporators.

ANOKA.—W. J. Annon has resigned his position as superintendent of the Anoka Water Works, Electric Light & Power Company to accept an appointment as postmaster of this city.

DAWSON.—Andrew Thompson, owner of the local electric light plant, states that he expects to increase the capacity of the plant 10 per cent. and will install a larger engine to meet the demand.

WARREN.—W. Haney, superintendent of the city lighting plant, reports that the matter of constructing a duplicate electric light plant has been placed in the hands of a committee who will engage an engineer and ask for bids.

THIEF RIVER FALLS.—It is proposed to install a new 100-kw. direct-current generator at the municipal electric light plant, and about 3500 feet of bare stranded cable, with a diameter of 500,000 cir. mils, will also be added.

BRECKENRIDGE.—Several improvements are under way at the municipal lighting plant, including a new building and the addition of a 400-h.p. boiler and a new pump for the water works, together with several line extensions.

LAKE CITY.—The Lake City Electric Light & Water Company is enlarging its power house in order to make room for a new 40-h.p. engine and a 30-kw. alternator. The system is being changed from direct to alternating current.

STILLWATER.—The City Council has granted to the Stillwater Gas & Electric Light Company a 10-year franchise to light the city. The company will install a new system of incandescent lights for the streets and will make various other improvements.

KEYSTONE.—The Keystone Lumber, Power & Development Company is the name of a concern recently organized for the purpose of utilizing the water power near here and furnishing electric light to the town. C. J. Patton is one of the promoters of the enterprise.

ST. CLOUD.—The Public Service Company has been reorganized with a capital of $500,000. It is proposed to dissolve the receivership of the street railway company and to incorporate it with the Public Service Company. About $230,000 will be expended in improvements to the electric light and street railway plants.

INTERNATIONAL FALLS.—Press reports state that the Koochiching Power Company, which is about to develop the water power of these falls, has awarded to the Alpena Portland Cement Company the contract for the cement to be used in the construction of the dam, paper and pulp mill. The contract is said to involve $100,000.

ST. PAUL.—The redraughted form of the ordinance permitting the Union Manufacturing Company to extend its electric lighting system in the western portion of St. Paul has been approved by the Board of Aldermen. The measure now provides for a bond of $25,000 and allows for other public service corporations to use the poles on the payment of a proportion of their cost.

GRACEVILLE.—It is proposed to increase the equipment of the municipal electric light plant this spring by the addition of a 125-kw. direct-current generator direct-connected to a tandem compound condensing Corliss engine with a speed of 90 r.p.m. The feeder lines will be reconstructed also, and thirty 5-ampere arc lights will be installed for street lighting. P. F. Daly is superintendent.

MISSISSIPPI.

NEW ALBANY.—Bids have been received for the construction of water works and an electric light plant.

PASS CHRISTIAN.—Bids for lighting the town with electricity are now being considered by the Town Council.

PORT GIBSON.—The city contemplates installing at the electric light plant a 125-h.p. return tubular boiler and stack.

HOUSTON.—At a recent election the citizens approved the proposed bond issue of $13,500 for establishing an electric light plant and water works.

GREENVILLE.—L. B. Bradley, receiver of the Greenville Light & Power Company, states that it is intended to install a complete re-equipment of the station.

MISSOURI.

COLUMBIA.—The city is installing a new plant and the machinery of the old one is for sale.

NEW FRANKLIN.—A local company has been granted a franchise to erect and maintain an electric light plant.

MEXICO.—At a special election, held for the purpose of deciding the question, a franchise for 20 years was granted to the Mexico Electric Light Company.

MOBERLY.—The Moberly Gas & Electric Company purposes reorganizing and rebuilding its plant this spring, it is said. J. Green is president of the company now.

HUNTSVILLE.—Extensive improvements are contemplated by the Huntsville Gas & Electric Light Company, which will make its plant practically as good as new.

ST. LOUIS.—The Adrian Light & Fuel Company has filed articles of incorporation, with a capital stock of $50,000. William McCabe and John Betz are among the incorporators.

LAMAR.—The Lamar Light & Water Company states that it will be in the market for another engine, boiler and alternator this spring. W. O. Settle is superintendent of the plant.

KANSAS CITY.—Articles of incorporation have been filed by the Holt Electric Company, in which the capital stock is placed at $20,000. The name of the company was subsequently changed to the Empire Electric Power & Supply Company.

MOBERLY.—This city and Huntsville will be connected by an electric line shortly. The Moberly & Missouri Electric Railway Company has been awarded the contract for lighting the city of Moberly, the building of the railway being included in the contract.

HANNIBAL.—The new electric light plant, which has been in course of construction recently, has been put in operation. The plant cost $100,000 and is thoroughly up-to-date in every respect. The street railway company has arranged to receive its motive power from the plant.

MACON.—By a detailed report submitted by the electric light and water works committee of the Council, it is shown that the municipal plants earned last year $867.76, the first time in the 15 years' existence of the utilities named that the balance has been on the right side of the ledger. The installation of meters and more systematic methods are said to have accomplished the reform and placed the city properties on a paying basis.

NEBRASKA.

HUMPHREY.—The Humphrey Electric Light & Telephone Company has increased its capital stock from $15,000 to $50,000.

OSCEOLA.—Clarence Miller, proprietor of the local electric light plant, states that he will build new lines this coming summer.

BLAIR.—The Blair Electric Light & Power Company proposes installing a new boiler and direct-current generator and establishing a day circuit.

TEKAMAH.—J. M. Crowell, City Clerk, writes that it was voted March 7 to issue $10,000 for the purchase of the present plant or the installation of a new one.

ALMA.—The city has voted for a bond issue of $20,000 for the construction of water works and an electric light plant. Bids for the work will be received April 15.

PONCA.—On the 4th of April the village will vote on the proposition of bonding the town to the amount of $6000 for the purpose of establishing a lighting system.

FREMONT.—The improvements which have been under way for some time at the Fremont light and water plant have been completed and the plant is now prepared to furnish a satisfactory day service.

CRETE.—The municipal authorities recently displaced the old alternator with a larger machine which is belt-connected to the engine. The old arc machine has been discarded and the street lighting is now done with alternating-current series enclosed arc lamps with a potential regulator.

PLATTSMOUTH.—At a meeting of the directors of the Nebraska Lighting Company the sum of $25,000 was appropriated for the purpose of entirely rebuilding the local gas plant. Plans were also considered for making extensive improvements to the electric light plant. The improvement work will begin as soon as the frost goes out of the ground.

NEVADA.

WELLS.—The Elks Electric Light & Power Company has been incorporated with a capital of $100,000, by A. W. Hesson, John J. Hylton, C. J. Hood, and others.

RENO.—Dr. W. H. Patterson, president of the Reno Power, Light & Water Company, recently disposed of his interest in the corporation and has tendered his resignation as president. He will be succeeded in that office by P. L. Flanigan.

RENO.—The Nevada Power Mining & Milling Company is to install two 750-kw. three-phase generating outfits in its power plant, where current will be generated for transmission at 30,000 volts to the Tonapah gold field and surrounding mining districts in Nevada. The transmission line will be about 100 miles long.

NEW HAMPSHIRE.

MONROE.—The Monroe Water Power Company has been incorporated for the purpose of constructing dams across the Connecticut River and furnishing electricity in this state and Vermont. A. S. Batchellor, of Littleton; Charles H. Hosford, of this city, and George Van Dyke, of Boston, Mass., are among the incorporators.

NEW JERSEY.

VINELAND.—A new boiler is to be added to the equipment of the Boro electric light plant.

BERNARDSVILLE.—The Bernards Water & Light Company expects to add a day circuit to its service after May 1.

PASSAIC.—The City Council has under consideration the establishment of a municipal lighting plant and will probably petition the Legislature for permission.

MADISON.—Articles of incorporation have been filed by the Western Water & Electric Company, having a capital stock of $100,000. Charles E. W. Smith, George M. Ward and John H. Gindrat are among the incorporators.

HACKENSACK.—As a result of the meeting of the directors of the Gas & Electric Company of Bergen County, and a session of the stockholders of the concern, the plan to lease the plant to the Public Service Corporation for 999 years was ratified.

PATERSON.—The Beaver Lake Company has been incorporated to build and operate water works, supply electric power, etc. It is capitalized at $50,000 and the incorporators are Wayne Dumont, John A. Kane, Frank Wilson, of Paterson, and Denton W. Clark, of Green Pond.

NEW MEXICO.

CARLSBAD.—Up to October of last year the Public Utilities Company leased power from a private dam which was washed away at that time. The company is now building a dam of its own, six miles southeast of this city on the Pecos River, at a cost of $8000. A 35-inch Samson turbine operating under a 12-foot head, will be installed for the present, and another will be added later. New leads are being run and the entire system is being thoroughly overhauled and put in first-class condition.

NEW YORK.

ONEIDA.—The Madison County Gas & Electric Company has secured the city lighting contract for $6965.

HOOSICK FALLS.—W. Stanley Bruen has been appointed manager of the Hoosick Falls Electric Company's plant.

WATKINS.—The Village Trustees are said to have selected an engineer to prepare plans for an electric light plant.

COHOCTON.—The question of constructing an electric light plant here is under discussion by the citizens and Council.

ILION.—Governor Higgins has signed the bill authorizing this town to issue $25,000 bonds for establishing an electric light plant.

WARRENSBURG.—John G. Smith, proprietor of the local electric light plant, contemplates installing a new turbine in the power house.

ALBANY.—The Albany Electric Illuminating Company has reduced the price of lighting current from 20 cents to 15 cents per kilowatt-hour.

CASTILE.—The superintendent of the municipal electric light plant writes that new lines for commercial lighting will be erected in the spring.

RHINEBECK.—The Dutchess Light, Heat & Power Company, in order to provide for its growing business, has purchased a 200-h.p. water-tube boiler.

JAMESTOWN.—It is proposed to install at the city electric light plant a new 200-kw. turbo-generator outfit, and 50 street lights will be added to the service.

NEW YORK CITY.—The Board of Aldermen on March 7 approved the resoluton of the Board of Estimate authorizing a bond issue of $600,000 for a municipal lighting plant.

SODUS.—The electric lighting franchise which was granted to some local parties about one year ago by the town board has been transferred to other business men of the place.

LANCASTER.—The Depew & Lancaster Light, Power & Conduit Company expects to be able to furnish both arc and incandescent lighting service to the village of Sloan by the 15th of May.

WATKINS.—The Watkins Consolidated Gas & Electric Light Company has been placed in the hands of a receiver. Senator Cassidy, of Montour Falls, has been appointed to act in that capacity.

JAMESVILLE.—The Thomas Millen Cement Company is reported to have in contemplation the construction of an electric plant, to be used for furnishing light and power for all the surrounding villages.

NIAGARA FALLS.—At a meeting of the Council a franchise was granted to the Niagara Falls Hydraulic Power & Manufacturing Company to build conduits in the city streets and lay cables for the distribution of electricity for heat, light and power purposes.

BROOKLYN.—The Mayor has approved the ordinance providing for an issue of corporate stock to the amount of $100,000 in order to provide additional means for placing all electrical conductors underground in the Borough under jurisdiction of the Fire Department.

EAST CREEK.—The East Creek Electric Light, Heat & Power Company, of which J. D. Cairns, of St. Johnsville, is manager, has in contemplation the establishment of another water power plant 3½ miles above its present plant. A three-phase transmission line, operating at 15,000 volts, will also be constructed.

NEW YORK CITY.—Plans for the city electric light plant for the Williamsburg Bridge have been filed. It will be the city's first venture in municipal ownership of light plants. The plant will be built in Tompkins Street, south of Delancey Slip, adjoining the new incineration plant, and will cost about $20,000.

PITTSFORD.—The Pittsford Light & Heat Company has been incorporated by Samuel Hutchinson, John Steve and B. N. Wiltsie. The company was organized with a capital of $10,000 for the purpose of lighting the streets and public and private buildings in the town of Pittsford. Its charter is for fifty years.

ONEIDA.—The Oneida Board of Public Works has ordered the Madison County Gas & Electric Company to remove its high-tension wires running through Madison Street to furnish power for the village of Canastota. Hereafter the Board of Public Works will oversee the erection of wires to carry high-tension current in this city.

TROY.—A petition for a renewal of the charter of the Hoosac Electric Power Company has been presented to the Legislature by W. S. Kelly, of North Adams, Mass. The charter was granted some time ago, but was dissolved shortly after. An immense power plant at Howe's pond has been planned by the company to supply water to Adams, North Adams and surrounding places.

MORAVIA.—The Moravia Electric Company states that it has in course of construction an entire new plant, in which will be installed a 200-h.p. McCormick turbine direct-connected to a 120-kw. 125-cycle General Electric generator. A new dam is being built and the depth increased from 8 feet to 12 feet. At some future date the company hopes to rebuild its transmission line.

LITTLE FALLS.—T. N. Lovenheim, owner of the Consumers' Electric Light Company, has sold a half interest in his plant to William La Due. Mr. Loveheim announces that the capacity of the plant will be doubled, a new dynamo having been ordered, which will increase the service by 1500 lamps. The company is also rebuilding the structure which was recently burned.

CANASTOTA.—The Electric Light Commission in its report on the construction of a municipal electric light plant, estimates the cost of such a plant with a capacity of 50 arc lights and 6000 incandescent lights at from $30,000 to $35,000. It is said that the question of bonding the village for $35,000 for the purpose of establishing a plant will be submitted to the taxpayers at the coming election.

NIAGARA FALLS.—The Niagara Falls Electrical Transmission Company is the name of a concern recently incorporated to do a natural gas and electricity business in Western New York. The company is capitalized at $100,000 and is chartered for 50 years. The directors are Harry Highland and Frank Dudley, of Niagara Falls, and Frederick Nicholls, E. R. Wood and R. E. Thompson, of Toronto.

BUFFALO.—City Engineer Morse submitted his estimate of the cost of a municipal lighting plant recently to the Board of Aldermen. He figures that it would cost $1,792,000 to build such a plant and that with the plant in operation the lights would cost the city $72.20 each per year as against the present cost of $75. The Board of Aldermen, however, by a vote of 16 to 5 approved the action of its committee on laws and legislation in holding up the municipal lighting plant bill, and it is said that it will be impossible to secure any legislation on the subject this year.

STAPLETON, S. I.—Mr. Calvin Detrick, president of the Staten Island Light, Heat & Power Company, died February 18. Mr. Detrick was an early promoter of electrical enterprises and erected the first electric lighting plant in the Borough of Richmond. He also constructed the system of hot water supply for that Borough and was the builder of the first underground electric light supply system in Philadelphia, Pa. He was born in Monroe County, Pa., May 4, 1838, and although his office was in this city his home was in Brooklyn at the time of his death.

BROOKLYN.—The Brooklyn Edison Electric Illuminating Company says that by the reduction

in the retail rates for electric lighting, which became operative on January 1 last, an electric sign with 24 incandescent lamps may be illuminated for as low as five cents an hour. The use of electric signs by progressive merchants in all parts of Brooklyn has increased very rapidly during the last two years. The Brooklyn Edison Company will supply an electric sign, designed and lettered to suit any business, and install it free of charge, including the wiring. The company retains title to the sign.

GREENPORT, L. I.—Municipal ownership of light and water plants has passed the experimental stage here and is pronounced a success. The annual report of the village trustees, who serve as light and water commissioners, as presented to the taxpayers recently, shows for the operating account of the light department total receipts of $10,595.02. The cost of operating was $6,028.40, including fuel, salaries, improvements, extension of lines, bonds maturing and interest on bonds outstanding. There remained on March 1 $823.39 in cash and 20 tons of coal valued at $85. The sum due for lights furnished in February is $266.05. The cash receipts from sale of light were $8,865.14. In addition the village has the benefit of about 150 street lights which are maintained without any assessment on the property whatever. That is, the plant earns in addition to the above figures, a sum sufficient to pay for 150 street lights at a rate of $18 each per annum, or $1,700, which the village would be obliged to pay were the plant owned by a private corporation. During the past year the plant has been very materially improved and is giving even better service than ever.

NORTH CAROLINA.

DUNN.—The direct-current lighting system of the city is to be changed to alternating current for commercial use.

TARBORO.—It is proposed to install at the municipal electric light plant a new 150-h.p. boiler. C. A. Johnson is manager.

DALLAS.—Dr. S. A. Wilkins, Clerk of the Town Board, writes that it proposed to construct an electric light plant at a cost of $3000.

FAYETTEVILLE.—A new boiler, engine and alternating-current dynamo are to be installed in the municipal electric light and power plant.

ASHEVILLE.—B. M. Lee, City Engineer, writes that the Legislature has granted this city permission to borrow money for an electric light plant, but it has not yet been decided whether to do the work or not.

SALISBURY.—The Salisbury & Spencer Railway Company is reported to have sold an interest in its system to the American Gas & Electric Company, of Providence, R. I., and it is stated that the line now under construction between Salisbury and Spencer will be completed and put into operation, and an electric light system will be installed at Spencer.

NORTH DAKOTA.

GRANVILLE.—The Telephone & Electric Light Company, of this city, has decided to incorporate with $10,000 capital.

GRAND FORKS.—The Council is reported to be considering the installation of a municipal plant for commercial lighting.

WALHALLA.—John F. Mayers, proprietor of the local lighting plant, states that they may add another dynamo and will probably increase the lines, as they expect to add between 200 and 300 incandescent lamps to their circuits.

OHIO.

SYCAMORE.—A new 60-kw. alternator is being installed in the village electric light plant.

CLEVELAND.—The capital stock of the Brilliant Electric Company has been increased from $75,000 to $125,000.

COLUMBUS.—The Washington Gas & Electric Company has increased its capital stock from $100,000 to $150,000.

MARTINS FERRY.—A new 500-h.p. Hamilton-Corliss engine is being installed in the municipal electric lighting plant.

ARCANUM.—The citizens are reported to have voted on March 7 to issue $38,000 bonds for water works and an electric light plant.

JAMESTOWN.—The Jamestown Electric Light Company has recently installed a new alternating current incandescent light dynamo.

DILLONVALE.—D. L. Renneker has sold his interest in the Dillonvale Electric Light Company to W. L. Cole, of this city.

CADIZ.—The Cadiz Electric Company has been incorporated with a capital of $12,000. J. V. Conner is the principal party interested.

BOWLING GREEN.—The Lake Erie, Bowling Green & Napoleon Railway Company is making extensions to its central hot water mains.

NEWARK.—Bids are now being considered for furnishing for a period of ten years a system of electric or gas lamps for street lighting

PORTAGE.—The Forde Lighting Company, of this city, has increased its capital stock from $25,000 to $50,000. W. W. Green is the president.

BELLEFONTAINE.—The city expects to rebuild, during the coming summer, its entire municipal lighting plant, for which $50,000 bonds will be issued.

CARROLLTON. — The Carrollton Electric Company will add a new engine, dynamo and boiler in the spring. E. L. Swann is manager of the plant.

COLUMBUS.—The Public Service Company has received the contract for lighting the state house for the ensuing year, on a bid of three cents per kilowatt.

LOVELAND.—The City Council is said to have granted to H. C. Hubbell, of Toledo, a franchise to construct water works and an electric light plant at Loveland.

HOLGATE.—Extensions to the electric and pipe lines in connection with the municipal electric light plant and water works, will be made this spring, involving an expenditure of $2000.

CINCINNATI.—Henry W. Sage has resigned as secretary of the Cincinnati Gas & Electric Company. He is 65 years of age and has been with the company since 1870, becoming secretary in 1882.

CLEVELAND.—The Gillen Electric Company has filed articles of incorporation, with a capital stock of $10,000. The incorporators are S. H. Gillen, D. F. Streb, W. S. Rowell and A. L. Vermilye.

WOODSFIELD.—It is possible that the 125-horse-power McEwen engine and the 150-h.p. tubular boiler, now in use in the municipal electric light plant, will be sold and replaced with a 125-h.p. gas engine.

RIDGEVILLE.—The Ridgeville Electric Light, Heat, Power & Water Company has filed articles of incorporation, with a capital stock of $5000. Joseph, Samuel C. and Arthur J. Lay are the incorporators.

SPRINGFIELD.—An ordinance has been introduced at Springfield to give the Home Heating, Light & Power Company a blanket franchise throughout the city. The company will compete for the street lighting.

CINCINNATI.—H. C. Hutchinson, for some years connected with the Cincinnati Gas & Electric Company, has accepted a position as eastern representative of the Philip Carey Manufacturing Company, with headquarters at Buffalo.

URBANA.—A new company, headed by C. H. Marvin and T. A. Edmondson, now holds a franchise for an electric lighting and hot-water heating plant in Urbana. Steps will be taken at once for the erection of a modern plant.

NILES.—The city light and water works contemplate changing the street lighting system from direct-current open-arc lights to alternating-current enclosed-arc lights; also the installation of either a 300-kw. turbine or direct-connected engine and generator and a new feed-water heater.

BERKELEY SPRINGS.—The Berkeley Springs Light & Water Company has filed articles of incorporation for the purpose of operating water works and electric light plants. The company's capital is stated as $25,000. Recent reports are to the effect that it is proposed to bond the city for $500,000, the proceeds to be used for the construction of water works, an electric light plant and a city hall.

READING.—The Council is preparing to hold an election to vote on issuing $25,000 bonds for improvements to the Reading electric light plant, as follows: Two 300-h.p. tubular boilers set up complete on iron girders with stacks; one 250-h.p. engine; one 200-kw. alternating-current dynamo, with pulley, switchboard, etc.; one 100-light tub transformer; 75 enclosed-arc lamps, 6.6-ampere series alternating; 200 35-feet 5 and 6-in. poles, wire, mast, arms, etc.

COLUMBUS.—It is said that the Columbus Railway & Light Company is negotiating for a lease on the property of the Columbus Gas Light & Heating Company, now that John G. Deshler has retired as the head of the latter, and that the trade will shortly be closed. It is further said that the railway and light company is after a lease on the property of the Public Service Company, but officials of the latter deny this. The older company is making an endeavor to secure all the public service plants in the city if possible.

OKLAHOMA TERRITORY

ALTUS.—The Altus Light, Power & Ice Company has filed its articles of incorporation, with a capital stock of $25,000. The incorporators are A. Rennell, of St. Louis; Henry Braun, of Guthrie, and others.

OREGON.

DALLAS.—The Dallas Electric Light Company, of which J. G. Van Orsdal is manager, will install shortly a 200-h.p. engine, a 125-h.p. boiler, and will make some line extensions.

ONTARIO.—Seymour H. Bell and Charles H. Chance, of Sumpter, have been granted a franchise for constructing and operating an electric light plant in this city, the plant to be in operation within eight months. The outlay involved will be about $25,000.

BAKER CITY.—The Baker Gas & Electric Company is reported to have been sold to an Eastern syndicate, represented by Isaac W. Anderson, of Spokane. It is stated that about $400,000 will be expended in improvements, enlarging the capacity of the plant, and in constructing a suburban railway to Haines and the Lower Powder River Valley.

PENNSYLVANIA.

DANVILLE.—The municipal lighting plant is now in operation and is giving satisfaction.

BEAVER.—A franchise has been granted to the Valley Electric Company, to furnish the city with light.

WERNERSVILLE.—Bids are being considered for the construction of an electric light plant to cost $3500.

KUTZTOWN.—The citizens have voted to issue $15,000 bonds for the construction of an electric light plant.

LANSDALE.—The citizens have voted to issue $25,000, part of which will be expended on improvements to the electric light plant.

FAIRCHANCE.—The Borough Council has granted a franchise to the West Penn Lighting Company to extend its lines over all the streets of the borough.

BROWNSVILLE.—The Brownsville Light, Heat & Power Company, of which J. M. Bell is manager, proposes installing a 250-h.p. engine and a 200-kw. generator.

MT. UNION.—The Mt. Union Silica Brick Company has been granted a franchise for the construction of an electric light plant to light the brick works and also to furnish light to the town.

WILLIAMSPORT.—The Citizens' Electric Company contemplates installing a 150-kw. water power plant and a 300-kw. fuel oil plant, as soon as the weather permits. J. Fisher is manager of the company.

CONNERSVILLE.—George B. Markle, of Hazleton, has purchased the General Gas, Electric Light & Power Company's plant at this place. Mr. Markle announces that he will spend a large sum of money in improvements and extensions.

LINFIELD.—The Linfield Electric Light Company has been incorporated, with a capital of $5000, by Horace Ashenfelter, Royersford; William S. Emlig, Philadelphia; G. E. Brownback, Linfield, and A. H. Fry, Jr., Philadelphia. The company will furnish electric light, heat and power.

TURTLE CREEK.—The Rose Hill Electric Light & Power Company, having a capital of $20,000, has been organized to establish a power plant for furnishing Turtle Creek and adjacent boroughs with light and power. William L. Ledger is president and C. R. Trevaskis, secretary.

DUNMORE.—The Dunmore Light, Heat & Power Company has organized by electing the following officers and directors: President, A. L. Snowden; secretary and treasurer, E. M. Stack; G. M. Hallstead, F. B. Bull, H. H. Knapp, M. J. Murray, R. D. Manley, John Carney and M. B. Freedman

SCRANTON.—The Scranton Illuminating, Light, Heat & Power Company has organized by the election of the following officers and directors: President, A. L. Snowden; vice-president, G. M. Hallstead; secretary and treasurer, E. M. Stack; W. F. Hallstead, M. W. Collins, Theodore G. Wolfe, Franklin Howell.

McKEESPORT.—The People's Ice, Light & Storage Company, of this place, is installing two 425-kw., 2200-volt Bullock alternating-current generators, two 640-h.p. Erie Ball compound engines, a Westinghouse exciter, a General Electric converter, and a Walker switchboard panel, to furnish light and power for the town.

SCRANTON.—The stockholders of the Suburban Electric Light Company have elected officers and directors as follows: President, A. L. Snowden; vice-president, G. M. Hallstead; secretary and treasurer, E. M. Stack; F. E. Platt, W. F. Hallstead, M. W. Collins, F. B. Bull, B. Moses and A. L. Francois. The old board was reduced.

UNIONTOWN.—The agreement of merger and consolidation, whereby eleven electric light companies have been consolidated, forming the Western Pennsylvania Electric Company, has been recorded. The capital stock is $337,500. The officers are: President, William S. Kuhn; vice-president, Jacob Van Wagener; secretary, Jesse H. Purdy, and Treasurer, John F. Cockburn, all of Pittsburg.

WILKESBARRE.—Contracts for new machinery and engines have been let by the Wyoming Valley Gas & Electric Company as a step toward the improvements the company is promising to residents of the West Side. The contracts call for an expenditure of about $50,000. It is also understood that the Wyoming Valley Gas & Electric Company has secured control of the Hazleton Gas Light Company, which is capitalized at $125,000.

HOMESTEAD.—Homestead is to have an independent electric light company, with George S. Debolt and W. S. B. Hays as its promoters. Announcement of the formation of a stock company was made recently, and it was stated that work on the erection of the plant would be commenced within a short time. Light and power will be sold in Homestead and surrounding boroughs, and power furnished to the Homestead & Mifflin Street Railway Company.

YORK.—It is stated that the newly organized Susquehanna Electric Power Company will establish an electric power plant at Conawingo Falls, in the lower Susquehanna River, during the coming spring. The company is capitalized at $12,000,000. They have secured the necessary grants of land on both sides of the river, with a view to beginning operations as early as possible. It is said that these falls will produce an enormous horse-power. A large reservoir will be built, which will serve to store water enough over night to assist the plant in the day time. The reservoir will be several miles long. Capitalists from New York, Philadelphia and Baltimore are behind the project.

RHODE ISLAND.

WICKFORD.—The Wickford Light & Water Company, which recently purchased the electric light plant here owned by H. S. Dixon, is having transformers and other apparatus placed in position. The plant will be connected with the power house of the Sea View Railway Company, which will in the future furnish the electric lights of Wickford.

PROVIDENCE.—Arthur B. Lisle, assistant manager of the Narragansett Electric Lighting Company, of this city, has resigned to engage in a brokerage business. Mr. Lisle has been with Mr. Marsden J. Perry, president of the company, as confidential clerk for about six years. He was also treasurer of the East Providence Water Company, and is interested in the Putnam (Conn.) Water & Lighting Company.

SOUTH CAROLINA.

DARLINGTON.—Reports are to the effect that the new owners of the Darlington Light & Water Company propose enlarging the plant. The company also contemplates installing a plant at Timmonsville.

SOUTH DAKOTA.

SPEARFISH.—The Homestead Mining Company is said to have purchased the Spearfish Electric Light & Power Company, the consideration in the transaction being $18,000.

MANDAN.—George Horn has sold out his interest in the Cavalier electric light plant to James Lang, who is now the sole owner. The plant will be enlarged and improved.

LEAD.—The Belt Light & Power Company contemplates installing three 500-kw. units, complete with boilers, etc., and 1000-h.p. in motors. Twenty miles of new power lines will be constructed also.

MARION.—The Marion Town Council has awarded to J. A. Heeren and other business men a franchise for the installation and operation of a lighting system. A water works system will also be constructed.

MADISON.—The municipal electric light plant is to be remodeled. Another boiler will be installed in the power house and a station regulator for the series incandescent street lighting will be added to the equipment sometime during the year.

TENNESSEE.

COLLIERVILLE.—It has been voted to issue bonds for the construction of an electric light plant.

ROCKWOOD.—A 180-h.p. engine will be installed in the city electric light plant during the summer.

SHELBYVILLE.—Correspondence is invited by the city of Shelbyville, looking to the installation of an electric light plant by the city.

COOKVILLE.—The contract for the electric light plant has been awarded to McDonald, McCoy & Co., of Chicago, on a bid of $25,159.

PULASKI.—The City Electric Light Company finds it necessary to increase the capacity of its plant, and the present equipment will be displaced by larger machines.

KNOXVILLE.—It is expected that the Knoxville Power Company will probably commence the construction of its power plant sometime during the coming summer.

BRISTOL.—Edward Durham, of Philadelphia, and W. B. Cutler, of Buffalo, have secured a franchise from the city to construct and operate an electric light plant.

HUNTINGTON.—The Mayor and Board of Aldermen have closed a deal with W. J. Holman, by which he takes charge of the city's electric light and water plant on a five-year lease.

BROWNSVILLE.—The Burt-Smith Company, owner of the electric light plant, contemplates installing during the year a 150-kw. dynamo, and will make other important improvements.

MURFREESBORO.—J. H. Nelson, proprietor of the local electric light plant, states that he expects to substitute at once an arc-light system for the present incandescent street lights.

JEFFERSON CITY.—The Jefferson City Electric Light Company, whose plant was destroyed by fire in January last, has purchased the Forche tannery property and will erect an electric light plant thereon.

NASHVILLE.—The City Council has passed an ordinance appropriating $12,600 for the purchase of a generating unit and $2500 for an arc lamp transformer, to be installed in the municipal electric light works.

DICKSON.—William McDonough, proprietor of the Dickson Machinery Repair Company, is making arrangements to put in an up-to-date electric light plant, which will enable him to furnish light to business houses and residences.

MEMPHIS.—The Merchants' Light & Power Company has been granted a thirty-year franchise by the City Council, in exchange for which the new company gives to the city of Memphis fifty arc lights to be erected along Main Street. The company is capitalized for $50,000, and will shortly be in the market for general equipment, the franchise granting the right to build and operate both gas and electric lighting and power systems.

CHATTANOOGA.—It has been announced that a lock-and-dam power plant, which will produce 30,000 horse-power will be erected at a point in the Tennessee River, near Kelly's Ferry, Chattanooga, Tenn. For some time the Government dredging boats have been busily engaged in dredging the river at Kelly's Ferry to determine the kind of foundation which may be secured for the dam. It has been found that a stone foundation is located in the bottom of the river, near the Ferry, and there the lock-and-dam power plant is to be erected by C. E. James, of this city, and Eastern capitalists. The Iona Cement Works, of Kansas, has purchased valuable lands near the site of the proposed plant, and a cement plant will be erected there with a capacity of 100 barrels per day as soon as sufficient power can be secured to run the plant. It is given out that work will actually begin on the new plant as soon as the spring freshets are over.

TEXAS.

LONE OAK.—W. R. Harrison is said to be contemplating the installation of an electric light plant here.

HAMILTON.—The Hamilton Light & Ice Company has been organized and incorporated with a capital of $20,000, for the purpose of establishing an electric light and ice plant. W. A. McSpadden, of Cisco; J. A. Muhl, of Waco, and C. Schuwirth, of Dallas, are among those interested in the project.

UTAH.

PRICE.—It is reported that a large electric plant is to be erected in Huntington Canyon, near this place. The projectors, D. C. Robbins and associates, are also getting rights-of-way over the roads of the county for an electric road.

SALT LAKE CITY.—The Utah Light & Railway Company recently made application to the City Council for a 50-year extension of its franchise, although it will be 42 years before the present franchise expires. The City Attorney, however, submitted an opinion to the Council, holding that that body cannot legally grant the application for such an extension. Samuel Newhouse, a large mine owner, submitted a counter proposition in which he stated that if given a franchise he would guarantee to furnish better light at from 25 to 30 per cent. lower than the rate now charged by the lighting company. Mr. Newhouse has deposited a certified check for $10,000 as evidence of good faith and announced that he will expend from $500,000 to $1,000,000 on his proposed steam-power plant.

VIRGINIA.

LYNCHBURG.—The City Clerk writes that a committee is looking into the matter of constructing a municipal electric light plant.

WINCHESTER.—Dr. H. H. McGuire is chairman of the committee which has under consideration the question of constructing an electric light plant, at a cost of about $25,000.

WASHINGTON.

BLAINE.—The Council has granted to H. L. Jenkins a franchise for the establishment of an electric lighting plant.

EVERETT.—The Everett Railway, Light & Water Company was recently incorporated at Wilmington, Del., with a capital stock of $2,000,000.

SOUTH BEND.—J. M. Entier has been granted a forty-year franchise to furnish electric power and lights in South Bend. Local capital is back of the new enterprise.

American Electrician.

Vol. XVII. New York, May, 1905. No. 5.

A MODERN ELECTRICALLY-DRIVEN MANUFACTURING PLANT.

NEW WORKS OF THE INGERSOLL-SERGEANT DRILL COMPANY AT PHILLIPSBURG, N. J.

The new manufacturing plant of the Ingersoll-Sergeant Drill Company, at Phillipsburg, N. J., embodies all that is recent in industrial practice, and illustrates to what an extent electricity influences modern manufacturing methods. The site is admirably located, so far as railroad facilities, abundant water supply and future extensions are concerned, and the various shops are arranged in logical sequence so that the products of manufacture pass progressively from one department to another until they finally emerge in their marketable shape.

The power house is centrally located, both with reference to the load and to the buildings which it supplies. It is built of brick and steel and is divided, as shown by Fig. 2, into a boiler and engine room. The boiler room has a maximum capacity of 2500 horse-power in boilers although but 1500 horse-power is at present installed. This is divided between three batteries, each battery consisting of two 250-horse-power Stirling water-tube boilers. Space is provided for an additional battery at each end of the boiler room. A 200-ft. Custodis stack is located at approximately the center of the building. This has an octagonal base 17 feet in diameter with an 8½-ft. flue. The boilers are fitted with Roney stokers arranged for burning anthracite slack with which is mixed bituminous slack in a proportion of about one to six. An elevated coal storage system of the Berquist suspension type is installed. This has a capacity of 1300 tons. The hoppers have a total width at the top of 24 feet and a depth of 14 feet, with a full load capacity of 7.56 tons per running foot. The delivery chutes have a measured capacity of approximately 450 pounds and are provided with shut-off valves at both ends. By this means a record is kept of the number of chute-fulls of coal delivered to the stokers, so that the coal consumption is readily obtainable. The coal is elevated from the receiving hopper and crusher in the basement to the bunkers by a McCaslin self-dumping bucket conveyor, arranged to handle either coal or ashes. A light structure is provided outside one end of the boiler room for the storage of ashes. These are received on the conveyor in the basement and are dumped through a special chute at the top to the outside elevated hopper. The conveyor is operated by a motor in the basement geared to drive the buckets at 40 feet per minute.

On each side of the stack in the boiler room is a Green economizer, one to provide for two batteries of boilers and the other to eventually serve three batteries. Feed-water is supplied by two 1000-h.p. outside-packed plunger-type Cameron pumps through a Cochrane feed-water heater supplied by the Harrison Safety Boiler Works, of Philadelphia, Pa. A 1000-h.p. Worthington underwriters' pump and a 300-h.p. Dean drip pump are also provided.

Boiler feed piping in duplicate is installed; one line running under the floor from the feed-water heater, and another line running overhead from the economizer. The two are interconnected to the feed connections at the rear steam drum. The pump connections are flexibly arranged with reference to the two lines, operating through either one or both.

The main and auxiliary steam headers are situated in a pit to the rear of the boilers and may be reached from the floor above through removable iron gratings. The main header is 14 ins. in diameter and the auxiliary 6 ins. in diameter. Both mains are interconnected and the main header is sectioned by gate valves so that if any section is disabled it may be by-passed by the auxiliary. Each boiler is connected to the steam header through an automatic non-return angle valve and a 6-in. steam line with easy bends. A gate valve is provided at the junction of this line with the header. The steam pipes to the engines pass from the header through the partition wall into the engine room basement, and thence to the engines. Condensation is cared for by drip pockets beneath the header at different points and by separators at each engine connection. The drip system is operated by an

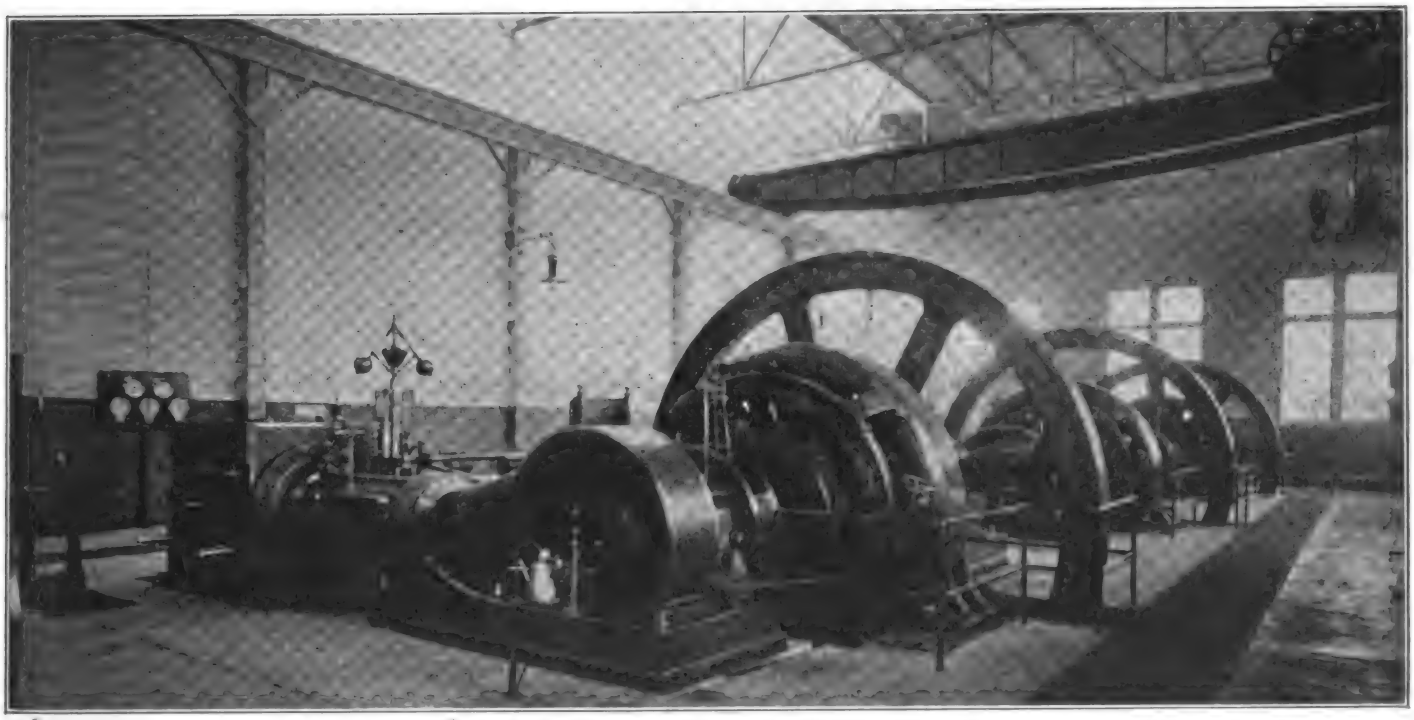

FIG. I.—MAIN GENERATING UNITS IN THE ENGINE ROOM OF THE INGERSOLL-SERGEANT DRILL COMPANY.

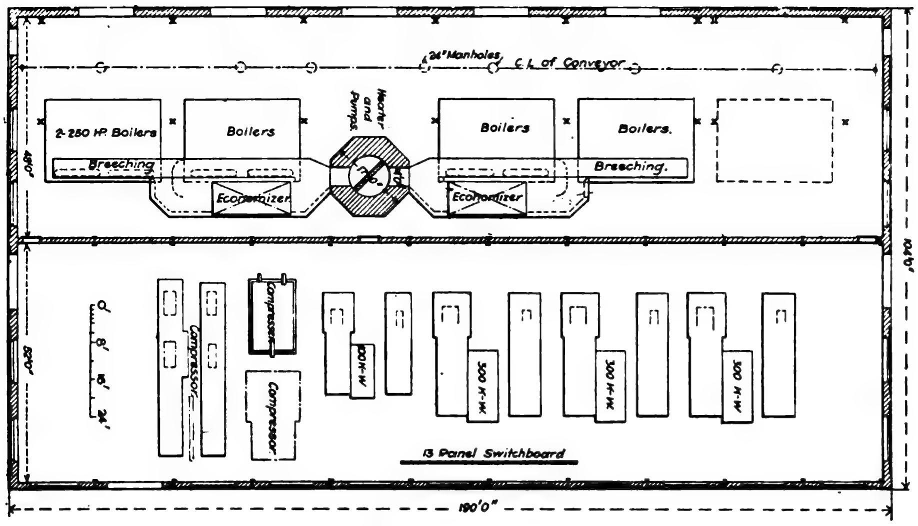

FIG. 2.—PLAN VIEW OF THE POWER HOUSE.

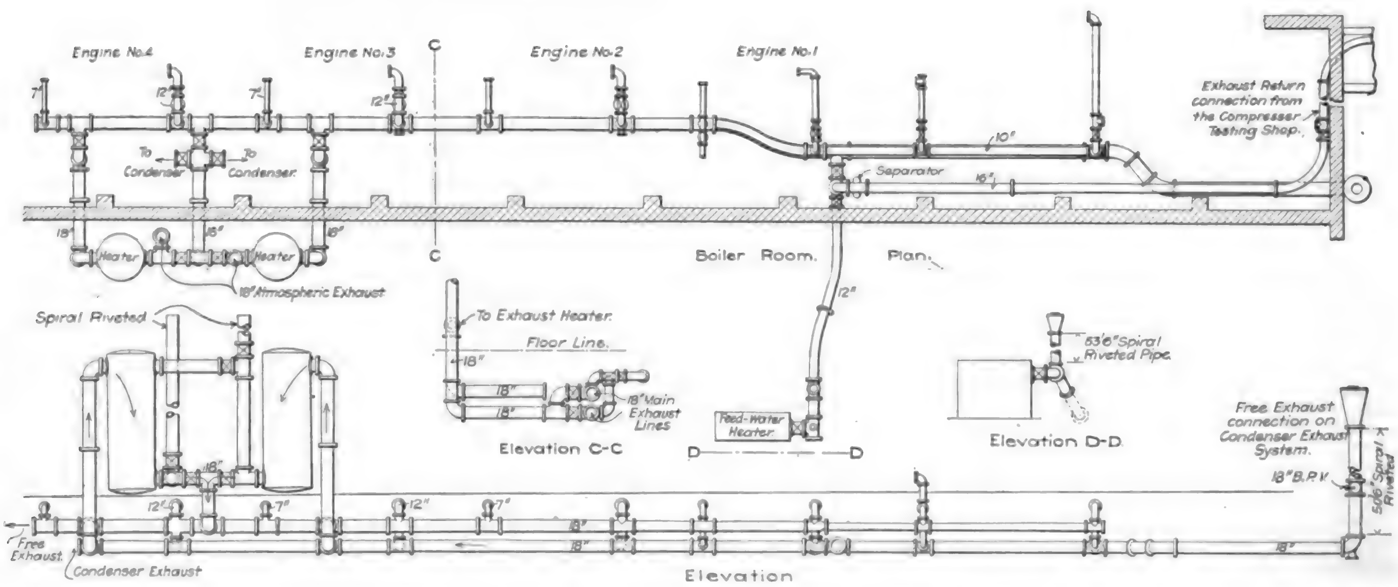

FIG. 3.—PLAN AND ELEVATION OF EXHAUST STEAM PIPING.

improved high-pressure return steam system which feeds to the boilers.

The engine room contains three 450-h.p. Cooper Corliss engines built by the C. & G. Cooper Company, of Mt. Vernon, Ohio. These engines are cross-compound, with cylinders 14¼ and 36 ins. in diameter by 36-in. stroke. They are direct-connected to 300-kw. direct-current generators furnished by the Crocker-Wheeler Company, of Ampere, N. J. A 100-kw. generator of similar type is driven by a 150-h.p. engine. Two air compressors are also installed. Two 30-h.p. DeLaval steam turbines are direct-connected to two centrifugal pumps which operate the hot water heating system for the shop buildings. The turbines are supplied with steam through special piping from one of the boilers which is equipped with a Foster superheater.

The exhaust piping system and the condensers are located in the basement of the engine room to the rear of the engines, the opening above being covered with removable iron gratings. There are two exhaust lines, one passing through the auxiliary exhaust apparatus, and the other direct to the atmosphere. These lines are both 18 ins. in diameter and are connected with each engine, the free exhaust connection being made through a Schutte automatic free exhaust valve. The line feeding to the condenser is arranged so as to permit the exhaust to pass directly into the condenser or first through the hot water heaters in the boiler room. The feed-water heater is connected to both exhaust mains.

The condensing system consists of two Conover jet condensers of 1000-h.p. capacity each. The water is pumped from a well supplied from a reservoir on the site having a capacity of 2,000,000 gallons. This reservoir or pond serves as a cooling basin for the hot condenser discharge. This passes first to a settling basin where it is freed from oil and then to the pond.

Reinforced concrete tunnels connect the various buildings with the power house. Through these tunnels steam, electricity and compressed air are supplied. The pipes are supported by adjustable swinging hangers which hook over pins fixed in the steel work of the tunnel. The wires are carried on insulators fastened to iron racks. A 10-in. main supplies steam to the air-compressor erecting shops for testing purposes and a 12-in. main carries the exhaust back to the

FIG. 4.—BOILER ROOM OF THE INGERSOLL-SERGEANT DRILL COMPANY.

condensers or heating system in the power house. The air compressed by the machines under test in the erecting shop is delivered to the power house augmenting that compressed in the latter place, thereby enabling this auxiliary supply to be used instead of being wasted. Compressed air is used considerably in all of the shops for hoists, hammers, riveters, motors and other apparatus. It is particularly useful in the foundry where it is employed in pneumatic sand sifters, tampers, tappers and chipping hammers.

The electrical distribution and drive form an interesting feature of the works. The general electrical distribution system is a two-wire system operating at 240 volts. In addition to this there are two intermediate wires in the machine shops for use in obtaining variable speeds at the motors of the motor-driven machine tools. The Crocker-Wheeler Company's multiple-voltage system of speed control is in use, and for producing the intermediate voltage a triplicate balancing rotary transformer is used, consisting of three Crocker-Wheeler machines mounted on a common base, and with the armatures on one shaft. The armatures are wound for 40, 80 and 120 volts respectively. By taking current from each of the three machines and by combining either two of them six voltages ranging as follows may be obtained: 40 volts, 80 volts, 120 volts, 160 volts, 200 volts and 240 volts. The rotary transformer is installed in the machine shop.

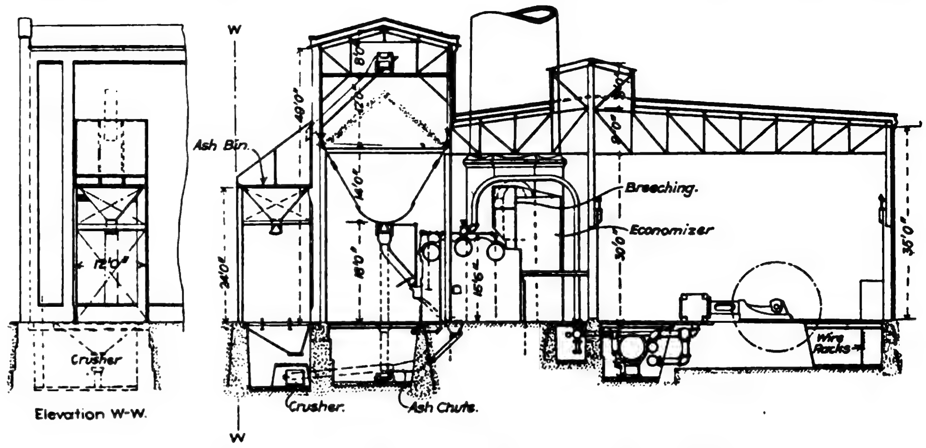

FIG. 5.—CROSS-SECTIONAL ELEVATION OF POWER HOUSE.

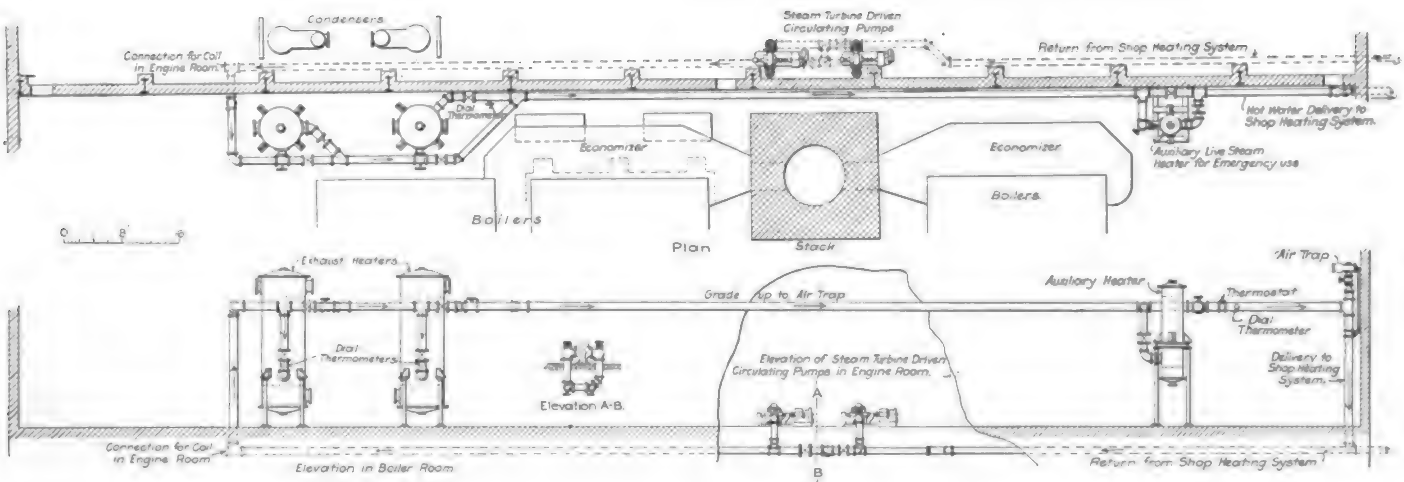

FIG. 6.—PLAN AND ELEVATION OF HOT-WATER HEATING SYSTEM.

FIG. 7.—ELECTRIC CABLES IN BASEMENT OF ENGINE ROOM.

All tools requiring a large amount of power and used on a variety of work are equipped with individual variable-speed motors. These are generally mounted on a bracket over the headstock on lathes; but in the case of planers, the motor is mounted above the housing on brackets. Heavy flywheels are used on the motor shafts for overcoming the strain on the motor at reversals of the platen. The method of driving boring mills is illustrated by Fig. 13. Here the motor is shown supported upon a bracket bolted to the rear of the housing.

In the lathes illustrated in Figs. 11 and 12 it will be noted that the drive to the headstock in each case is through gearing reductions to an intemediate shaft and from the latter to the spindle through either one of three gear changes as desired, the latter being capable of easy change. In this way an individual drive with a motor having a three to one speed range, and a suitable arrangement of change gears, will increase the effective speed range of the motor some three or four times and give the tool from 60 to 80 speeds, which will easily cover any possible class of work to which it may be subjected. The style of change gear

mechanism that supplied is that recommended by the Crocker-Wheeler Company. This mechanism provides a system of levers by which either three or four-gear trains may be thrown in, and yet so interlocked that two of them cannot be thrown in together and damage the gearing.

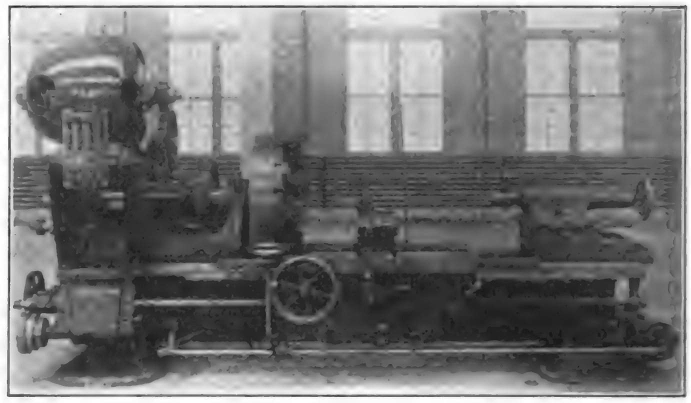

FIG. 11.—MOTOR-DRIVEN ENGINE LATHE.

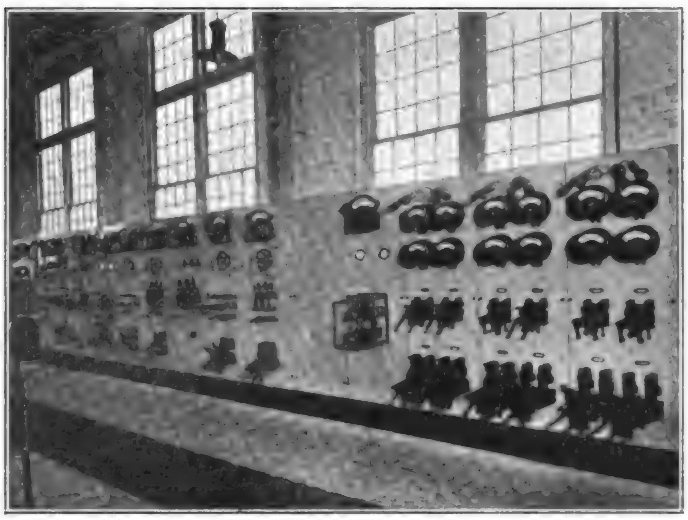

FIG. 9.—MAIN SWITCHBOARD.

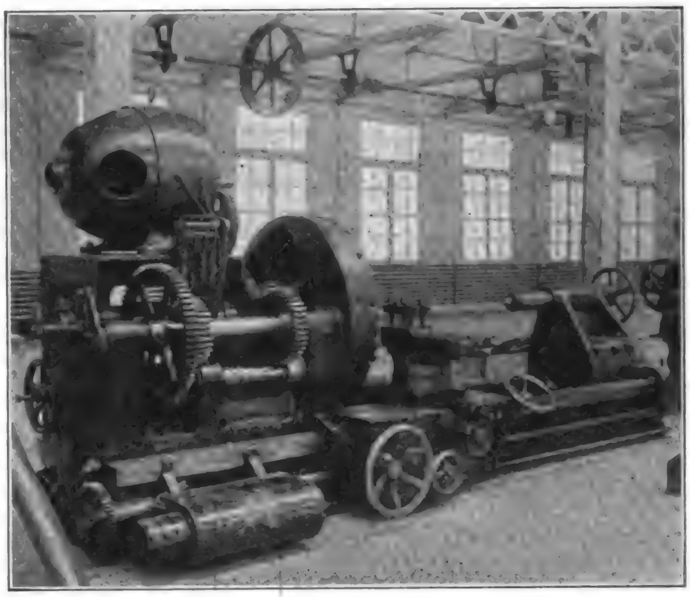

FIG. 12.—APPLICATION OF MOTOR DRIVE TO A HEAVY LATHE.

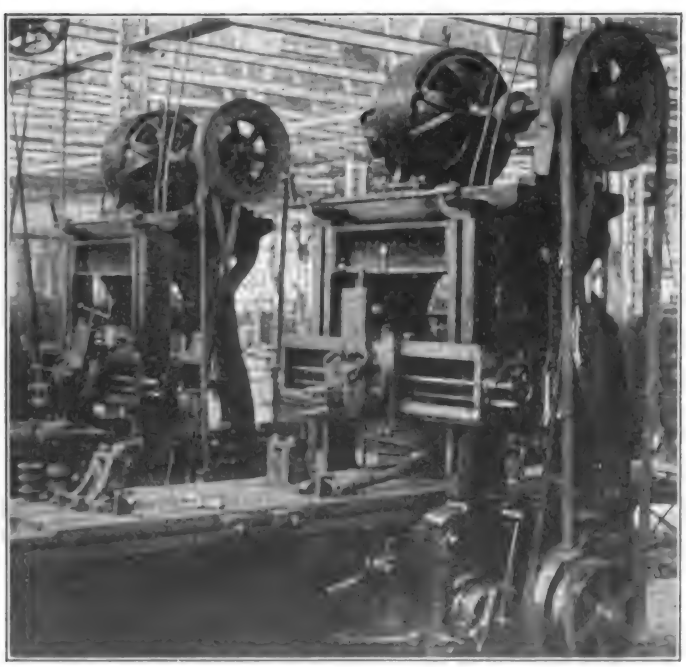

FIG. 10.—MOTOR-DRIVEN PLANERS WITH FLY-WHEELS.

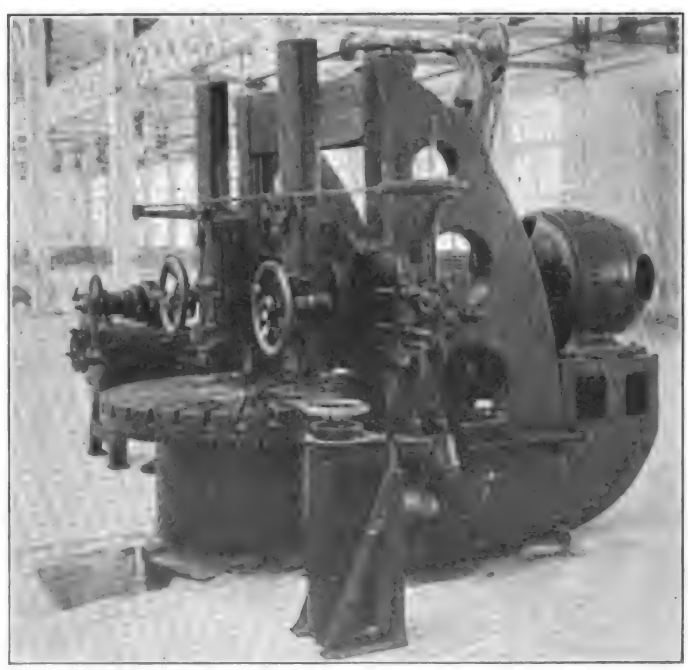

FIG. 13.—MOTOR-DRIVEN BORING MILL.

The arrangement of controllers for the lathes, which is of vital importance to the success of the method of driving, is interesting and novel. In each case the controller is mounted upon the bed close to the floor with a splined shaft either connected directly to the controller or to it through gearing. A bracket on the carriage supporting the controller hand wheel carries also the splined shaft which it turns through a sliding sleeve which keys with it, so that the controller is readily handled from a horizontal hand wheel. In the case of the boring mill the controller is mounted upon

a pedestal bracket at the side of the tool as shown.

The four wires of the multiple-voltage system are carried through the machine shop beneath the floor in bituminized conduits about 12 in. under the surface, these conduits ending in floor plate openings, adjacent to every building column. The branch leads are connected to the mains under the floor plate and run out through a short length of loricated conduit. This does not interfere with shop operations, as the floor box is covered ordinarily by a heavy cast-iron plate. The branch conduit leading up through the floor is in most cases run up alongside the nearby building column, although it is equally possible, if it is desired to locate the machine half-way between two adjacent columns, to chisel a channel in the concrete floor and locate another loricated conduit so as to lead more closely to the machine to be served.

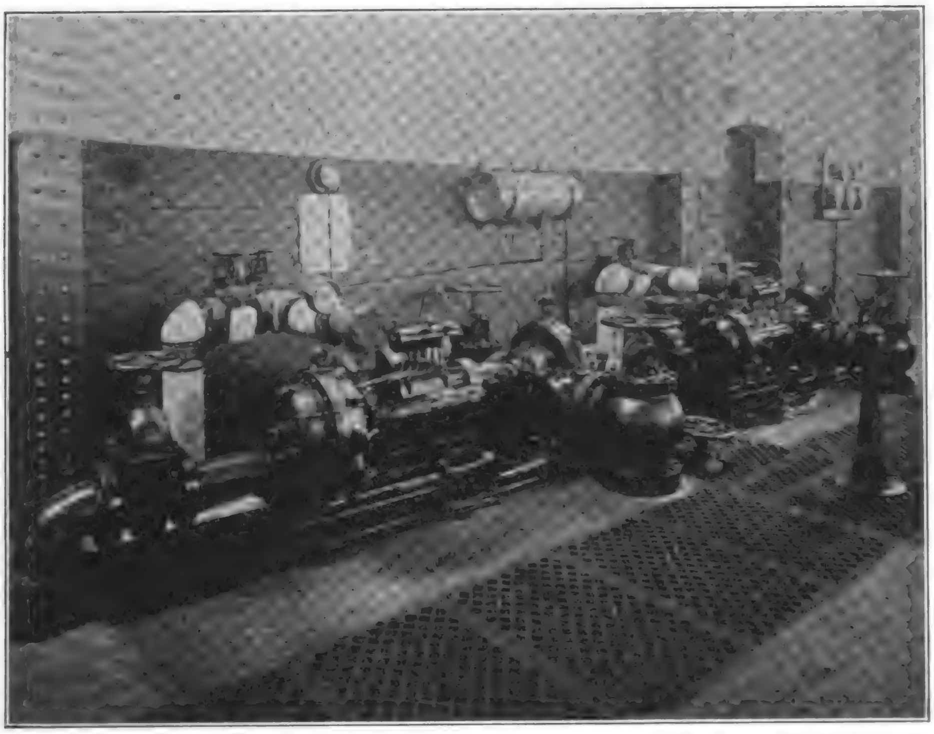

FIG. 14.—STEAM TURBINE-DRIVEN PUMPS FOR HEATING SYSTEM.

THE STEAM PIPING OF A SMALL LIGHTING STATION.

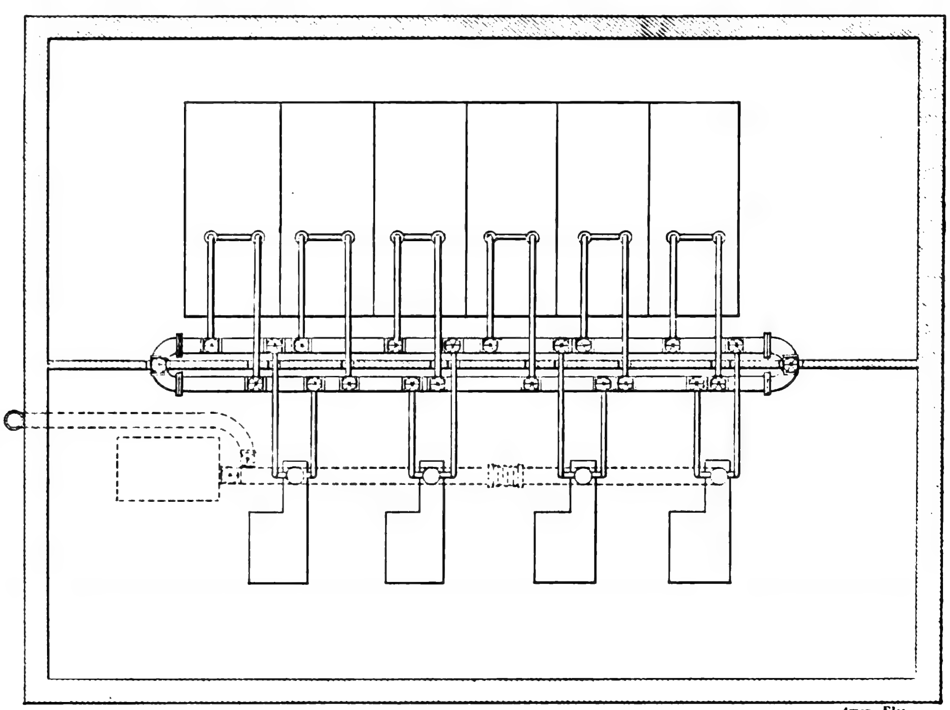
BY R. T. STROHM.

The lay out of the steam piping system of a station depends largely upon the relative location of the boiler and the engine room, and this location is influenced by the formation or shape of the ground plot upon which the building stands. It often happens that the available ground is of irregular outline, while the conditions are such as to necessitate the utilization of the entire area. This may lead to an unusual, and, perhaps, not the most desirable, lay out of the steam piping.

At present two systems are in general use. One is known as the duplicate system, and the other as the sectional or subdivided header system. Both systems embody meritorious features, and have their respective advocates; yet there is considerable difference of opinion, in many cases, as to which is preferable. The fact that both systems are used indicates that the question of superiority is far from settled.

To illustrate the first system, consider the piping of a 500-h.p. lighting plant arranged as shown in Fig. 1. The engine and boiler rooms lie side by side, and are separated by a fire wall which completely isolates one from the other. The engine room contains four high-speed automatic engines of 125 horse-power apiece, the cylinder of each engine being 12 inches diameter by 16 inches stroke, and the speed, 250 r.p.m. The plant is non-condensing.

Assume that each engine uses 30 pounds of steam per indicated horse-power per hour, with cut-off at quarter stroke and a boiler pressure of 90 pounds. There being 500 horse-power in all, the steam required per hour for the engines alone would be $500 \times 30 = 15,000$ pounds. Taking into account a possible overload of 10 per cent and allowing a further 10 per cent for the auxiliary apparatus, the total steam per hour required of the boilers would be $15,000 + (.20 \times 15,000) = 18,000$ pounds. This evaporation, on the basis of 160 degrees feed-water temperature and 90 pounds pressure is equivalent to 19,620 units of evaporation, or, as commonly expressed, about 600 boiler horse-power. This may be obtained by the use of six 100-h.p. return tubular boilers, arranged as shown in Fig. 1.



Amer. Elec.

FIG. 1.—APPLICATION OF THE DUPLICATE STEAM PIPING SYSTEM.

To find the size of steam pipe required for each engine, use the formula

$$d = D\sqrt{\frac{S \times r.p.m.}{36,000}}$$

in which

d = diameter of steam pipe in inches;
D = diameter of cylinder in inches;
S = stroke of engine in inches;
$r.p.m.$ = revolutions per minute of engine.

Substituting the several values of the known quantities, and solving, we have

$$d = 12\sqrt{\frac{16 \times 250}{36,000}} = 4 \text{ inches.}$$

In other words, the diameter of the steam supply pipe to each engine would be 4 inches.

One pound of steam at 90 pounds gauge pressure has a volume of about $4\frac{1}{6}$ cubic feet. Hence, as one boiler evaporates about 3300 pounds per hour, the discharge pipe from each boiler must be large enough to carry away a volume of $3300 \times 4\frac{1}{6} = 13,750$ cu. ft. per hour, or 230 cu. ft. per minute. On the basis of a rate of flow not exceeding 6000 feet per minute, the area of

the pipe would be 230 ÷ 6000 = .0383 square foot, or nearly 5½ square inches, which is about the area of a 2⅝-inch pipe. Inasmuch as the boiler may be forced to some extent, and as 2⅝ inches lies between 2½ and 3 inches which represent the commercial sizes of pipe, the 3-inch pipe would be chosen as the size to be used between the boilers and the main.

The main steam pipe, or header, must carry the combined discharge of the six boilers, and hence its area must be at least equal to the combined area of the six discharge pipes from the boilers. The area of a 3-inch pipe is 7 inches, so the main steam pipe should have an area of $7 \times 6 = 42$ square inches. This corresponds to a diameter of about 7½ inches, so that an 8-inch header would doubtless be used. This, it will be observed, has the same area as the four steam pipes leading to the engines, which is an additional check upon the calculations.

The header, or steam main, forms a ring which is made up of two straight, parallel lines of pipe joined at their ends by bends. One-half lies in the engine room and the other half in the boiler room, the whole being carried on a double line of brackets fixed to the dividing wall. The ring itself contains but two valves, one being placed in each of the end bends. These two main valves are provided with by-passes, for use in warming up, so as to avoid sudden strains on the cold piping.

On the boiler nozzle is fixed a Y-fitting, to which two discharge pipes are attached. One of these pipes connects with one-half of the main header, and the other pipe with the other half. Each branch pipe from the boiler consists of a long bend as shown in the sectional elevation, Fig. 2, which is connected into the top of the main by an angle stop valve. This avoids any possibility of forming pockets for the collection of water, since the condensation occurring in the bend will run back into the boiler.

Similarly, each engine has two long-bend supply pipes, one leading from each half of the main, being connected into the top of it by angle valves, as shown. These two supply pipes are connected to a separator, just above the throttle valve on the engine, the separator thus acting practically as a Y joining the two. Besides removing the entrained moisture from the steam just previous to its admission to the engine, the separator forms a steam reservoir of considerable volume from which the engine draws its supply. This acts to prevent excessive wire-drawing and assists greatly in obtaining a higher and more uniform pressure during the admission period. The use of a receiver of this kind is especially desirable on high-speed engines.

The ring, or main header, is firmly anchored at its middle point, on each side. All expansion and contraction is thus divided, half occurring in either direction. Owing to the fact that all connecting pipes are bends of long radius having considerable span, the movement of the main is readily taken up by the elasticity of the pipes, so that no further provision is necessary in regard to expansion or contraction.

It is evident from this arrangement, that the possibility of a complete shut-down is very remote, and that it could be brought about only by some extremely unusual accident. There is practically a double system of steam piping on which to depend. The boilers can be made to discharge into one-half of the main by simply closing the stop valves leading to the other half, and the engines may be made to take their steam from either side, by a similar procedure. Thus, in case of damage to the main header in the engine room, the two main valves in the end bends would be closed as well as all angle valves on the damaged half. This would cut out of service the broken section, yet would not interfere in the least with continuous working.

The diameter of the exhaust pipe from each engine is found by the formula

$$d = D\sqrt{\frac{S \times r.p.m.}{24{,}000}}$$

in which the letters have the same significance as in the previous formula for finding the diameter of the live steam pipe, with the exception of d, which represents the diameter of the exhaust pipe. Substituting the various known values, it will be found that $d = 5$ inches. As there are four engines, the area of the main exhaust pipe must be four times that of a single pipe from one engine, so that a 10-inch exhaust line is required.

The exhaust pipe from each engine passes vertically downward through the flooring of the engine room, and connects with the main. The latter conveys the exhaust steam to a feed-water heater, in which as much of the heat as possible is given to the boiler feed-water. The remainder of the exhaust is led to a vertical pipe just outside the wall, which extends upward, terminating in an exhaust head somewhat above the level of the roof. A by-pass is provided in the main so that the steam may be passed directly into the atmosphere around the heater, in case the latter requires cleaning or repairs. Provision for expansion or contraction of the exhaust main is made by inserting a corrugated expansion joint, as shown in the plan, Fig. 1. Each exhaust pipe is fitted with a valve which may be closed when the engine is out of service, thus preventing the exhaust from the other engines from backing up into it.

The main steam pipes and the separators are furnished with drip pipes connected to steam traps, which collect and deliver all condensation and entrained moisture to the feed-water heater. This is an open heater and contains provision for the separation of oil from the engine exhaust and auxiliary exhaust. It is also provided with a float for regulating the influx of cold water to supplement the condensed exhaust, according to the demands made upon the heater by the boiler feed pump. The drip pipes from the high-pressure steam pipes are all well protected by non-conducting coverings.

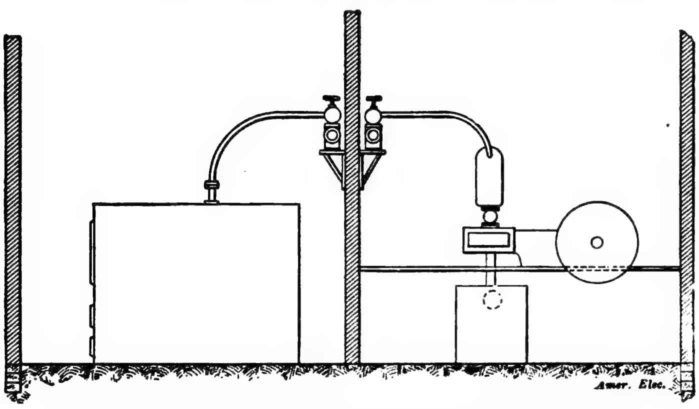


FIG. 2.—ELEVATION OF DUPLICATE STEAM PIPING SYSTEM.

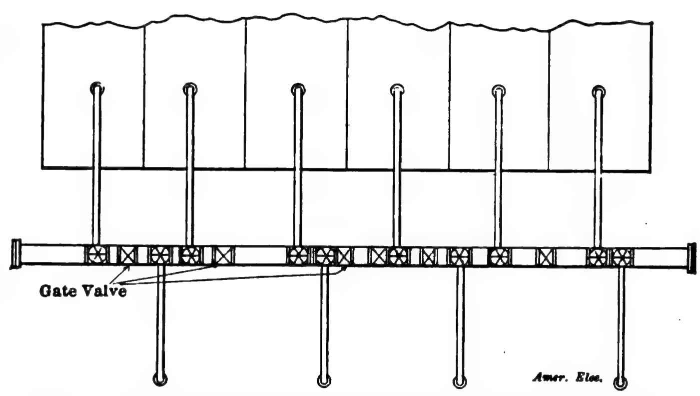

FIG. 3.—APPLICATION OF THE SECTIONAL SYSTEM STEAM PIPING.

If the system of sectional subdivision is employed, the ring header is replaced by a single straight main supported on the boiler room side of the division wall, as in Fig. 3. This main is connected to each boiler and to each engine by long, easy bends. The valves used are gate valves throughout and are located so as to divide the main into a number of sections, as shown. In case of failure of any section, the valves at each end of it are closed, as well as the valves in the discharge pipe leading from the boiler or boilers which feed into the section. Thus, the remaining engines may be run by the boilers not cut out, which likewise prevents complete shut-down.

The plant is thus divided into two distinct portions, each cut off from communication with the other. This is the one objection which can be urged against this system of piping. There can be no intercommunication of boilers and engines located on opposite sides of the broken section. There are many points in favor of the sectional system, however; first, it is cheaper to install than the ring system; second, its arrangement is far simpler; third,

it is less liable to leakage on account of the smaller number of joints; and, fourth, it may be put up in less time and with less labor.

The duplicate, or ring system, possesses the same advantages of freedom from shut-down of any portion of the plant and the ability to run any or all engines from the entire battery of boilers, as required. Against it may be rightly urged the increased cost of installation; greater loss due to increased radiating surface; added complexity of arrangement; and doubled expense in the matter of supports and drip piping. There are certain conditions under which it is not advisable to install anything but the duplicate system, but for plants consisting of a considerable number of units of the same size and type, the sectional system commends itself as the most desirable to use.

A COMPARISON OF COMMON METHODS OF MAGNET COIL WINDING.

BY CHARLES R. UNDERHILL.

The chief aim in modern electromagnet coil winding is to obtain the greatest amount of copper in a winding, with the least amount of insulating material, without sacrificing the dielectric strength of the insulation on the wire. As a basis on which to compute the ratios between the copper and insulation in the methods of winding under discussion, a winding volume of one cubic inch is assumed. For the sake of simplicity, it is assumed also, for this particular case, that the loss at the ends of the winding, due to the change in direction in the turns of each layer from right to left and *vice versa*, is negligible. The weight of wire and insulation that will just fill a bobbin accommodating a cubic inch of material may be expressed as "pounds per cubic inch." Likewise the resistance may also be expressed as "ohms per cubic inch." It is therefore obvious that having found the weight or resistance per cubic inch of winding volume, the total weight

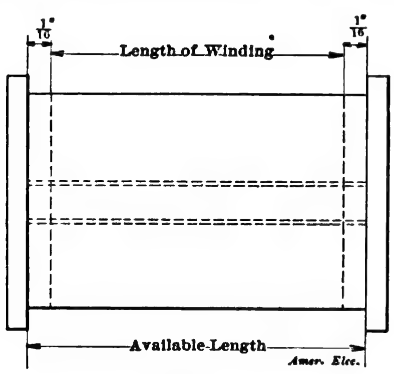

FIG. 1.

or resistance for any bobbin may be calculated by multiplying the volume of the winding in cubic inches by the weight or resistance per cubic inch.

The wires commonly used in practice are round, and in this article a round copper wire is always meant unless otherwise stated. If the ideal condition could be realized, the insulation on the wire would be so reduced as to occupy no space at all, but still retain its insulating qualities. With this ideal condition, only the actual copper need be considered. If a bobbin were wound with various sizes of bare wire the weight of the wire would always be the same, regardless of the diameter of the wire, the "pounds per cubic inch" being constant.

The most common method of insulating wires is to cover them with silk, cotton or paper, and where the coil is subjected to much heat asbestos is used. Another method, generally known as the bare wire

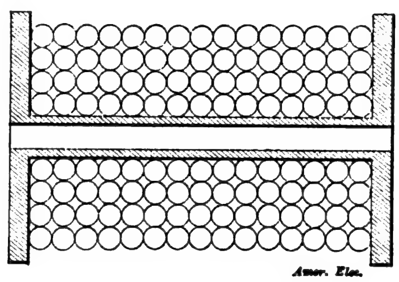

FIG. 2.

winding, consists of turns of bare wire insulated from each other, as the wire is coiled into the winding by a silk or cotton thread parallel with the wire, both being wound on simultaneously. The layers are separated from each other by suitable sheets of paper. Sometimes the silk or cotton thread is omitted and a wax or varnish used to hold the turns of wire in place and to insulate between the turns. In this case, as in the preceding one, paper is placed between the layers.

A method which has been the object of much experiment is to cover the wire with a thin uniform coating of flexible insulating compound which shall be hard enough to prevent being cut through by other turns of the winding and yet be so pliable as not to chip or crack when bent at reasonably low temperatures. Furthermore, the coating of compound should not be materially affected by heat.

For wires between Nos. 20 and 36 B. & S. gauge, the diameter of the cotton insulated wire is usually 4 mils over the diameter of the bare wire, and the increase in diameter due to silk is usually 2 mils, although on the finer wires 1.5 mils increase is often used.

In the so-called bare wire method the least distance between the turns of wire, edge to edge, is 3 mils for sizes from No. 34 to No. 40 B. & S. gauge and approximately one-half the diameter of the wire for larger sizes. The paper commonly used for this purpose is approximately 1 mil thick, and as it is necessary to use two thicknesses of paper between each layer the distance between the layers, edge to edge, is 2 mils. The increase due to the compound on the enamelled wires is sometimes less than 1 mil, making it far superior to any of the other methods as to the amount of copper that may be obtained in a given winding volume.

In the so-called bare wire winding an allowance of at least 1/16 inch must be made at each end of the winding for small coils and a greater allowance for larger diameters and coarser wires. Thus for an ordinary ringer magnet, where the winding length for a silk or cotton-covered wire winding would be 2⅛ inches, the winding length for the so-called bare wire winding would be 2 inches, which makes a loss in the winding volume of over 6 per cent. For a coil 1⅛ inches long and of the same diameter, the loss would be 12½ per cent. This will be understood by reference to Fig. 1. In the theoretical or ideal bare wire winding, there would be a certain imbedding of the wires which would amount to 7.3 per cent. With the silk or cotton insulated wire, however, the insulation spreads laterally, due to the vertical tension during the winding process, so that this imbedding may be neglected for the finer sizes of wire. There is no appreciable imbedding of the bare wire winding with paper between the layers as the paper tends to prevent this.

In comparing the economy of the different methods of insulating and winding coils with each other and with the theoretical bare wire winding, no imbedding will be assumed, but the wires will be considered to lie as in Fig. 2. The longitudinal cross-section of the winding may then be considered as consisting of a great many squares, each square representing the space occupied by each turn of wire and its insulation, as in Fig. 3. The total number of turns, then, for any given size of wire and fixed winding volume will be equal to the available cubic space divided by the space occupied by each turn of wire, the cross-sectional area of each turn including insulation space being considered the square of the diameter of the insulated wire for covered wires, and the product of [the diameter of the bare wire + the lateral insulation] × [the diameter of the bare wire + the vertical insulation] for the so-called bare wire winding.

To ascertain the total length of wire in a winding, the average length of all the turns is multiplied by the number of turns. The resistance of the winding is then equal to the "ohms per inch" for the wire multiplied by the total length of the wire in inches. Likewise, the weight of copper in the winding will be equal to the "pounds per inch" for the wire multiplied by the total length of the wire in inches. As the

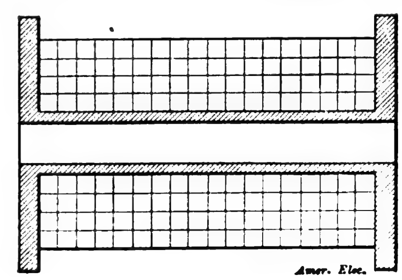

FIG. 3.

resistance of a wire is inversely proportional to the square of its diameter, while the space it occupies is also inversely proportional to the square of its diameter, the "ohms per cubic inch" for any size of bare wire in the ideal case would be inversely proportional to the fourth power of its

diameter. In practice, however, the space occupied by the wire and insulation is greater than the square of the diameter of the wire, and therefore the "ohms per cubic inch" will not vary in the same ratio as for the ideal bare wire winding, and consequently so much resistance cannot be obtained in the same winding volume. In any case, the "ohms per cubic inch" are equal to the "pounds per cubic inch" multiplied by the "ohms per pound."

Fig. 4 is a chart showing the relative weights of copper which may be obtained with the various methods of insulating and winding. The values in the curve for the so-called bare wire winding with paper between the layers must be reduced by varying percentages according to the ratio of "actual length of winding" to "available winding length," or the length available for a covered wire winding.

The magnetic effect due to any winding is proportional to the ampere-turns in the winding, and since, for fixed dimensions, the resistance of the winding is directly proportional to the number of turns, the ampere-turns will be constant for a given diameter of wire and fixed voltage, regardless of the number of turns or resistance, neglecting changes in specific resistance due to temperature variation. For example, assume a winding of such dimensions and size of wire that the average resistance per turn of wire is one ohm, and that with a very thin insulation one is able to obtain 10,000 turns of wire in the winding. With a terminal e.m.f. of 100 volts the current will be 0.01 ampere and the magnetizing power 0.01 × 10,000 = 100 ampere-turns. Now, if the same bobbin be rewound to the same dimensions as before with the same size of wire, but with so thick an insulation on the wire that only 100 turns can be got into the winding, the resistance will be 100 ohms and the current 1 ampere, but the ampere-turns will be 100 as before. In the first case, however, only 0.01 ampere and 100 volts, or 1 watt, were required to produce 100 ampere-turns in the winding, while in the latter case 1 ampere and 100 volts, or 100 watts, were required for the same number of ampere-turns.

It is therefore evident that the economy of operating a copper wire electromagnetic winding depends upon the thinness of the insulating material, or, to be exact, the degree of utilization of the available winding space for the copper conductor.

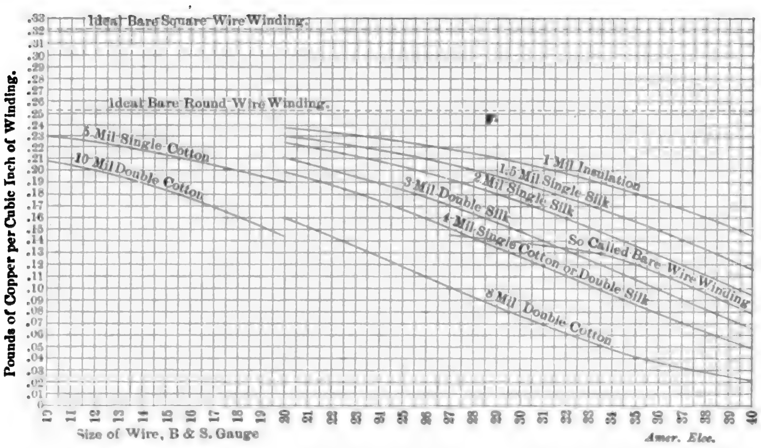

FIG. 4.—CHART SHOWING RELATIVE WEIGHTS OF INSULATED COPPER WIRE.

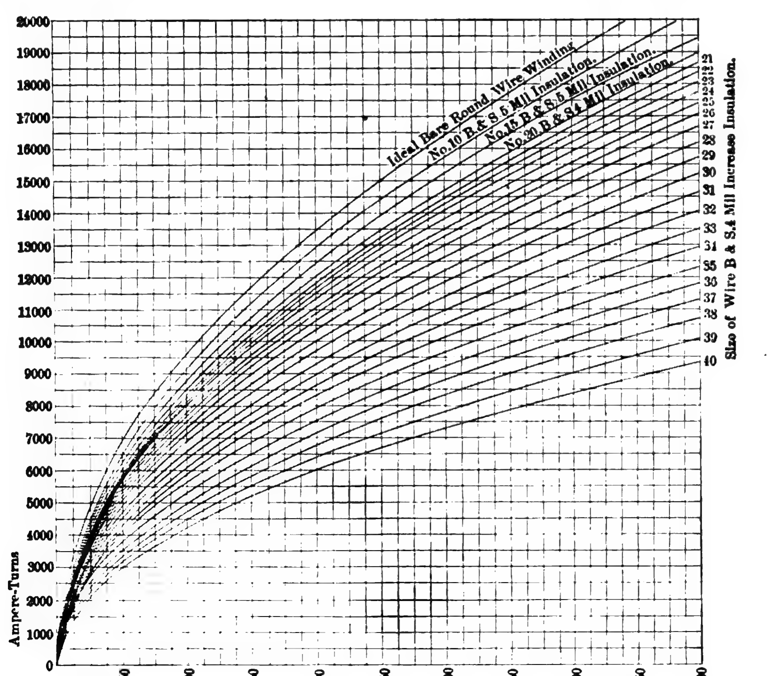

FIG. 5.—CHART SHOWING RATIO BETWEEN WATTS AND AMPERE-TURNS.

Fig. 5 shows the ratio between watts and ampere-turns for a specific case, with various B. & S. gauge copper wires insulated to a 4-mil increase. The dotted curve shows the watts required with the ideal bare round wire winding for any diameter of wire, this being constant since the insulation is zero. This shows very plainly why a bobbin wound for a given number of watts on a high voltage will not produce the same magnetic effect for the same number of watts on a much lower voltage.

AUTOMATIC BLOCK SIGNALS.

BY RALPH SCOTT.

The Taylor Electric Interlocking Signal.

In the Taylor interlocking signal system the following apparatus is used: (*a*) A storage battery or other similar source of electrical energy. (*b*) An interlocking machine, in which the circuit controllers of the various switches and signals are connected with mechanically interlocked levers, this machine being provided with electromagnetic indication arrangements. (*c*) Insulated wires for conducting current to the various motors, on the switches and signals, from the circuit controllers of *b*. (*d*) Switch and signal motors or other electromagnetic devices provided with means for opening the circuit operating the switch or signal devices immediately after these have performed their proper movement and are located in position. These are provided with the necessary means for closing the indication circuit at the same time. (*e*) The switches and signals to be operated.

In Fig. 72 the various connections of the battery, interlocking machine, indicating mechanism, circuit controllers and switch and signal motors are shown, together with a switch, a two-arm home signal, a distant signal, and a dwarf signal.

The interlocking machine forms the arrangement by which all of the various devices are required to fulfill their functions.

Each of the levers of the interlocking machine, of which four are shown in the engraving, is provided with a cam slot by means of which a motion of the tappet bar is transmitted, which motion is intermittent, according to the longitudinal position in which the cam slot is machined.

Interlocking between the various levers is effected by these tappet bars; that is, unless they are in the correct positions it will be impossible to move any of them. If the tappet bars are cross-locked in such a manner that in order to move lever 4 levers 1, 2 and 3 must be moved in the order given, it would be impossible to move lever 4 if this order were in any way changed.

The circuit controllers, indicated in the figure, consist of metallic steps, which are carried on movable blocks of insulating material, connected to the levers which make contact with the brushes supported on fixed blocks.

As will be evident from the figure, during the first quarter of the travel of the lever the tappet bar is moved through one-half its stroke by means of the cam slot. This movement makes no change in the

connections on the circuit controller, the contact pieces merely sliding along the same brushes. This movement, however, causes the preliminary locking of the controller routes which conflict with the new motion of the lever.

At the half and three-quarter positions of the lever the contact pieces are carried from the brushes at one end of the controller to the brushes at the other end. The tappet bar, however, during this motion, remains stationary, the lever being stopped for a short time at this point by the latch, *L*, until released by the indication magnet, *I*. When the indication magnet releases the lever, it requires but a slight pull to move the latter to the end of its travel.

During this final quarter movement of the lever the electrical connections are unchanged, being the same as at the end of the third quarter of the stroke.

The tappet bar, however, is moved to the end of its stroke and releases the other levers which do not conflict with the new position to which the lever is moved. The switch movement is controlled by means of two wires and the main common wire.

The indication currents generated by the switch motor itself during its revolution are transmitted through the same wires and the indication common wire. In one position of the lever one of the wires is the control wire, and in the other position it is the indication wire. When the lever is moved to the other position, this order is reversed. Each of these latter wires is connected to two brushes of the circuit controller, one brush at each end.

The controller, therefore, reverses the connections of these wires so that in one position of the lever one is connected to the positive end of the battery in series with the safety magnet, *S*, and to the operating bus-bar; while the other end is connected to the common indication wires through the indication magnet, *I*, and to the indication bus-bar. In the other position, these connections are reversed. By means of the pole-changing switch, *P*, located in the switch itself, the switch is also controlled.

This pole-changer is automatically shifted by means of the switch lock bolt, during the latter part of its movement, and after the latter has passed entirely through the lock rod, connection being made between the movable part of the pole-changer and the mechanism represented at the rod. This pole-changer has two movable contacts and eight fixed contact points.

The armature terminals are connected respectively to two of these fixed contact points. One field terminal is similarly connected to two other of these points, each of the control wires being connected to the two remaining points. The other field terminal is connected to the common main wire.

These connections are made in such a manner that in one position of the pole-changer one of the armature terminals is connected to one of the control wires and the other armature terminal is connected to the field coils, while in the other position the latter terminal is connected to the other control wire and the former to the field coil. The diagram represents the connections as they normally are. The switch normal control wire in this position is connected to the battery, no current flowing, because at the pole-changing switch there is a disconnection.

If the lever, 3, is reversed, the reverse control wire is put in connection with the battery, a current thus flowing from the plus side of the battery to *K*, the operating bus-bar, the fuse wire, magnet, *S*, controller, contacts 6 and 8, reverse-control wire, pole-changer contacts, 15 and 16, the switch motor armature, pole-changer contacts, 11 and 12, the motor field coils, and then to the main common return and back to battery.

This battery is, as has been stated before, a storage battery which has been charged by means of a portable generating set, from time to time.

Current is continued until the switch has completed its movement and is locked in this latter position. Before this locking occurs, the lock rod shifts the pole-changer from contacts 15 and 16, to contacts 13 and 14, also from contacts 11 and 12 to contacts 9 and 10, thus disconnecting the reverse control wire from the armature and connecting the terminal, *a*, with the field coils and the terminal, *b*, with the reverse indication wire.

Just here a very important function is performed. As soon as the electric motor speeds up it develops a counter electromotive force; then when the current is cut off, the momentum continues the development of this counter-current, the useful function of which will be shown later.

The latter connections made by the pole-changer are such that the counter current leaves the armature at the terminal, *a*, and causes the same field flux that the driving current has caused; also passing through the main common to the indication common and through the following circuit: Indication common, magnetic cut-out, *H*, switch *J*, indication bus-bar, indication magnet, I^3, the circuit controller contacts, 4 and 2, reverse indication wire, pole-changer contacts, 10 and 9, to the terminal, *b*, of the armature, thus causing the indication magnet, I^3, to be energized, which releases the locking on the lever, 3, as follows:

Before the current passes through the magnet, I^3, the latch, L^3, is in a horizontal position with respect to the lever, 3, being held in position by the small dog, P^3, thus preventing the completion of the stroke of the lever, 3, because of the fact that the projection, Q^3, on the lever, engages with a similar projection on the end of lever L^3.

The indication magnet then lifts up its armature, T^3, which moves its plunger up and strikes the dog, P^3, in such a manner that it is thrown from under the latch, L^3, thus permitting the latter to drop and allowing the stroke of the lever to be completed. It is evident that in order that the indication current may flow through the magnet, I^3, it is necessary that the driving current must be cut off; that the indication wire must be put in connection with the armature, and also that the connections between the armature and fields of the motor be reversed.

The first of these conditions could be caused by a broken wire, the second by a cross between the indication wire and the armature wire, and the third by breaks and crosses in the armature and field wires. However, these three conditions would require a state of affairs which it might be said would be impossible of accidental creation.

It is evident that while the switch is being moved the connection between the normal and reverse control wires would cause the battery current to be sent through the indication magnet, thereby giving a false indication, but this is prevented by the following scheme:

A safety magnet, *S*, is placed directly beneath the indication magnet, I^3, the indication armature resting normally on the poles of this magnet. Since this magnet is in series with the battery, and connected to the control wires, all battery current must be sent through this safety magnet.

Were the two wires connected, the entire current, both that flowing through the switch motor and also that passing to the indication magnet, must pass through the safety magnet, so that if the entire current returned by way of the indication magnet, the current in this magnet would not be greater than the current in the safety magnet, and as the armature rests on the safety magnet itself for a short distance from the indication magnet, the latter cannot lift this armature.

If at the same time any of these wires were broken, even in the safety coils, it would cut off all current, since these are coils in series with the battery.

By moving lever 3 back to its normal position, the normal control wire is connected, through the safety magnet, *S*, with the battery. Thus, a current is sent through the switch motor, and passes from terminal *b* to the terminal *a*, through the armature which is in the reverse direction to that sent through the motor on reversing the switch; the current flowing through the fields in the same manner as before.

This reverses, therefore, the direction of rotation of the armature, the switch being moved back to the position it assumed at first. When the movement is completed, pole-changer *P* is moved back to the position shown in the figure, the indication current being generated as above shown. This current passes from the terminal *b* to the terminal *a* through the normal indication wire, the latter being formerly the reverse control wire.

As stated above, the current through the field coils is in the same direction as before. *P* is operated automatically by the lock rod in the latter part of its movement, and is also under the control of the lever by means of the magnets, *M* and *M'*. The former has one terminal connected to the main common wire, the other terminal being connected to the normal control wire. The latter magnet has one terminal connected to the main common wire, the other terminal being connected to the reverse control wire. When the normal control wire is connected to the bat-

tery, a current will flow through the magnet, *M*, while, when the reverse control wire is connected to the battery, current flows through the magnet, *M'*. These currents are sufficiently strong to cause a shifting of the pole-changer, whenever it is locked in position by the lock bolt, which is during the entire switch movement except at the first and last fractions of an inch.

Current is sent out through the reverse control wire whenever lever 3 is reversed, hence to reverse the switch motion current passing through the switch motor, in the right direction, it is necessary to reverse this switch and also the current through the magnet, *M'*.

This latter current has a tendency to hold the pole-changer in such a position that the current in the motor is maintained.

It is sometimes necessary, as is the case when the rails are blocked with snow, to put the switch back to its normal position before it has completed its reverse movement.

To do this, it is only necessary to put the lever back to its normal position, which sends a current through the normal control wire and the magnet, *M;* the magnet, *M*, being energized, the pole-changer is shifted to the other side, and into such a position that the current from the normal control wire which passes through the motor, is in a direction to put the rail switch in a normal position.

At the end of the movement, the pole-changer will be shifted back to the position shown in the diagram, the indication current being developed as shown. When the magnet, *M*, shifts the pole-changer, no current is sent through the indication magnet because of the fact that the controller connected to the lever is in the wrong position with respect to the former; and is not developed in case the magnet fails to work because of the fact that the connections between the armature and the field coils are in the wrong direction to develop it.

If they were reversed, however, this would occur; but this condition cannot happen. The circuit-breaker, operated automatically by the switch movement, but not shown in the diagram, is provided to cut off the current from the magnets, *M* and *M'*, when the switch is in either extreme position.

The foregoing description, while rather complicated, shows with what thoroughness the inventor of this system went about his work, and produced an arrangement which is remarkable for its extreme reliability in operation.

In Fig. 72, the home signal having two arms is represented as operated by one operating machine through a switch box connected to the switch as a selector, this being accomplished by the operation of one lever. Each of the signal arms is counterweighted by means of a weight at the end of a lever, to each end of which the end of a chain is attached. This chain passes around a chain sheave which is connected to and operated by the above machine. This chain sheave is provided with webs to hold the chains in their proper position, and also to grip the chain.

When the motor armature is operated in but one direction, one of these levers will be moved, while if the armature is operated in the other direction the other lever will be moved. The direction of the armature is controlled by the position of the reversing switch, which changes the contacts as required. Each of the signal arms controls, through a short rod a circuit-breaker. A circuit-breaker, operated by the home or upper arm has four contacts; one pair for controlling its motor circuit and the other pair for controlling the circuit of the distant arm, this being the case when the home arm is at the clear position.

The lower arm circuit-breaker has only two contacts, and these only for controlling its own motor, since the distant arm has no further control over any other signal arm. The signal controller, connected to the lever mechanism in the interlocking machine has two pairs of stationary contacts, one for normal connections and the other for reverse connections, this being accomplished by a sliding contact piece, which is connected to the lever and moved by the latter motion.

One of the reverse contacts is connected with the plus end of the battery, one of the normal contacts being connected to the common indication wire, the other two remaining contacts being connected with one end of the indication magnet, the other end of this indication magnet being connected to the signal control wire; one wire only being necessary for either single-arm or double-arm signal, for both control indication positions. After lever No. 2 being reversed, the control wire becomes connected with the battery, through the indication magnet, I^2, and also through the sliding contact of the circuit controller.

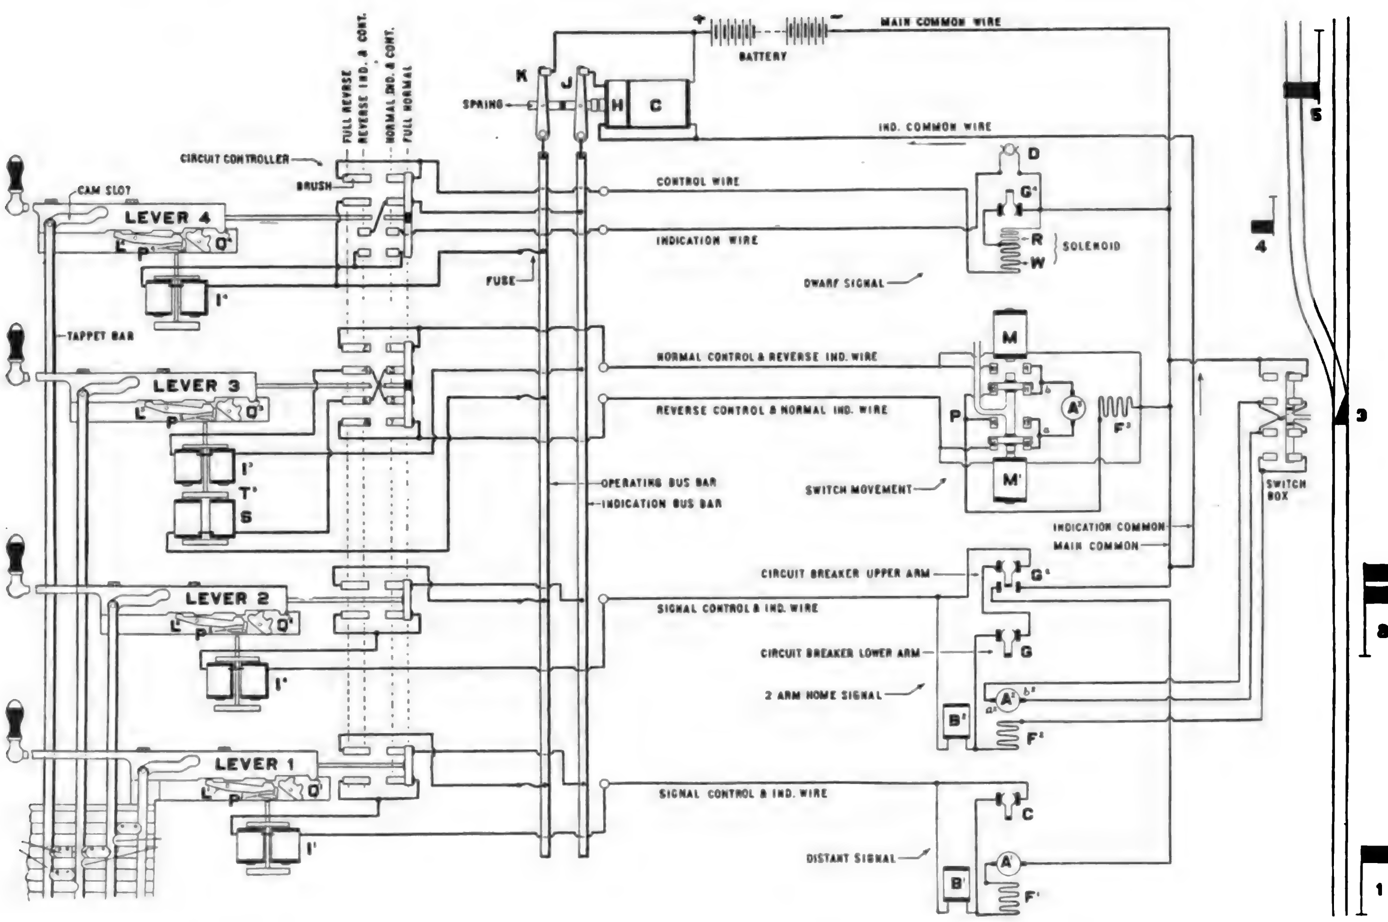

FIG. 72.—TAYLOR ELECTRIC INTERLOCKING SIGNAL SYSTEM.

This current flows through the indication magnet, the two circuit-breakers in series, the control wire, the motor field coils, F^2, one of the contacts of the switch box, the armature, A^2, and thence through another contact in the switch box to the main common.

If the switch box be normal, this current causes the armature of the motor to rotate in such a direction as to move the home arm to clear. When this home arm is at the clear position, the circuit-breaker, G^2, opens the circuit, and at the same time, during the latter part of its movement, closes the circuit of the distant signal. The circuit-breakers, being shunted by the break magnet, B^2, of very high resistance; the current is not suddenly ceased, but it is reduced to a very small figure by the high resistance of the shunt magnet.

This brake magnet, being energized, retards the disc carried on the shaft of the armature and thus brings the armature to rest. This holds the signal in the clear position, as long as the lever, 2, remains in the reverse position, to which it has been thrown. Since the current which operates the signal has passed through the indication magnet, I^2, the lever, 2, is released by the latch, L^2, and thus permitted to make its full movement to the reverse position.

However, this does not indicate that the signal has moved entirely to the clear position, but this is not necessary, since the indication of the clear position of the signal would be of little use, as no locking is released by the final part of the stroke of the lever, except that between the home and the distance signal; and this, as has been shown above, is already provided for by the circuit-breaker. which is controlled by the home signal.

When lever 2 is in the normal position the circuit to the break magnet is opened at the controller, the control wire being then connected with the indication common wire through the indication magnet. This causes the motor brake to be released and allows the signal arm to return to its normal position by the action of gravity on the counter weight.

The falling counter weight also sets the motor armature into a backward rotation, which develops a certain amount of electromotive force, then when the signal arm is nearly at its normal position, the circuit-breaker, G^2, assumes its normal position, thus closing the circuit of the current developed in the armature.

The path of this current is as follows: Leaving the armature at the brush, B^2, it passes through the switch box and the main common wire to the indication common and the coil H, then through the indication bus-bar, indication magnet, control wire, circuit-breaker, and fields of the motor, finally passing through the switch box and back to the motor armature.

This current, in passing through this circuit, causes the indication magnet, I^2, to be energized, thus releasing the lever, and allowing the final part of its movement to be made. The armature, in delivering up its energy, is caused to develop a retarding torque, thus bringing it to rest much quicker than otherwise, and also serving as a sort of dash-pot to the falling counter weight, thereby eliminating any destructive effects which might be produced were not the armature circuit closed. If at the same time that the lever, 2, is reversed, the switch box be reversed, the current, after passing through the field coils, will also pass through the switch box, and through the armature by way of the circuit, b^2, a^2.

This current rotates the armature in the right direction to clear the distant signal. The break magnet in this case is put into circuit by the lower circuit-breaker on the distance arm. When the lower arm is again in its normal position, the indication current is developed, by utilizing the rotation of the armature, in the same manner as has been described for the home arm.

This current flows in the same direction and through the same circuit, except the direction in the armature is changed, and also the two wires connected to the switch box are reversed.

In Fig. 72 the dwarf signal, with its connections is also shown. This signal is operated by a solenoid, which has two windings, one of very low resistance and the other of very high resistance. The low resistance winding is called the working coil and is shown at W in the figure. The other winding is of very high resistance and serves to retain the armature of the solenoid in the position given it by the working coil. This retaining coil is shown at R in the figure.

This dwarf signal solenoid also operates two circuit-breakers, which are controlled directly by the signal arm; one of these circuit-breakers controlling the indication circuit and being closed only when the signal is in the normal position, and the other controlling the working circuit and opening each time the signal is reversed.

The dwarf signal circuit controller, connected to the operating lever, is provided with eight fixed contact pieces, and two movable flexible contact strips. Two of these contacts are much longer than the others, and are situated at the end of the controller, connecting with the movable strip during the entire movement of the lever. The other two contacts at each end are short, and make contact with the other movable strip only when the lever is brought to a stop by the latch, L^4.

Since it would be an undue complication to derive a current from a solenoid for the purpose of indication as is done in the case of the home and distant signal motors, and also the switch motors, the indication current is obtained directly from the battery. One terminal of the indication magnet is connected always to the positive pole of the battery, the dwarf circuit controller connections being such that when the lever is at the normal indication point, the control wire is connected to the indication bus-bar, the other terminal of the indication magnet being connected to the indication wire. In the reverse indication position, the control wire is connected to the plus pole of the battery, the other terminal of the indication magnet being connected to the negative pole, through a circuit including the indication common and main common wires. In the full normal and reverse positions the control wire has the same connections that it acquires at the same indication points; the indication magnet being cut off to prevent a needless flow of current through its coils. If the lever, 4, is reversed, the control wire becomes connected to the battery, while the current flows through the working coil, W, and circuit-breaker, G^4, to the main common wire. This causes the signal arm to be moved to the clear position and also opens the circuit-breaker, which puts in circuit the retaining coil, which latter is in shunt with the circuit-breaker. The current in this retaining coil holds the signal arm in the clear position. The indication magnet is at the same time connected to the battery at the point of indication, and allows of the release of the lever to make its final movement to the reverse position. As has been shown with the high signal, this does not indicate that the signal has moved to the clear position, but in this case, also, it is not necessary to have any indication, because of the fact that there is no locking to be released, by the remainder of the movement of the lever to the reverse position.

The only reason for employing this arrangement of connections is to use a standard lever for both switch and signal levers. If the lever, 4, is forced back to the normal position, the retaining coil is short-circuited, and the signal returns to its normal position upon the lever reaching this normal position. Circuit-breaker D connects the common wire at the signal with the indication wire, and, as soon as the movement of the lever to the normal position has connected one terminal of the indication magnet with the indication wire, a current flows through this magnet, and releases the lever from the latch, L^4, thus allowing it to be forced to the full normal position.

It is evident from the number and operation of each of the circuit wires that if crosses between these should become of accidental creation, the various devices would be extremely liable to cause false indications, thus introducing dangerous factors into the system. To serve as a protection against these bad effects, the following scheme is used: J and K are two switches, electrically independent, and held normally closed by current passing through the coil C. When switch K is opened the battery is not connected in any way with the various circuits. When the switch J is open, all wires are disconnected from the indication common wire. Current passing through the coil C takes the following circuit: Plus pole of the battery, the coil, indication common, main common, and returns to battery. Another low-resistance coil, H, is wound on the same magnet core with the coil C. This coil H forms part of the indication common. All indication currents, therefore, from the signal and switch motors, must necessarily flow through the indication common, and through the coil H in such a direction that the latter assists the coil C to hold the switches closed. Since the indication common is connected to the

other, and to the main common, and this to the negative pole of the battery, then any current that might flow from the battery through the coil *H*, will pass in the opposite direction to that shown above, and cause the coil, *H*, to neutralize the effect of the current in *C*, and thus throw the switch open. By inspecting the diagram, it will be noticed that all wires that are in connection with the above coil and its functions are connected at the interlocking machine to the minus pole of the battery through the indication bus-bar, the switch and the coil, *H*, and also the indication and main common wires, so that current passing through any of these wires, on account of a cross with a live wire, will flow back through this coil *H*, in such a direction as to open the cut-out, and thus cut off current from the battery, which will render impossible any wrong movement, since we will have no current to effect this movement. The resistance of this path of the current is much less than that through the motor and main common wires; therefore, the greatest part of this current, due to a cross, must flow through the coil, *H*. The relation of the turns of the coil *H* and *C* is such that any current due to a cross and strong enough to operate the motor will also throw open the switch and cut off all current from the battery, before it can flow through the motor. The indication common wire is connected to the main common wire at some distance from the interlocking machine. The reason for such a connection is to avoid the drop in voltage in the main common wire, which occurs on working a switch motor or number of such. If this indication common wire were connected directly at the battery, this drop in voltage would tend to force the current back through the indication wires of the other magnets, not being operated, and would, in many cases, cause the switch to be opened and thus cause unnecessary annoyance and delay. By connecting the indication common at some distance from the battery at the main common, this drop in voltage is avoided and the safety factor is not lessened, since a break in either wire would open the switch.

Abstracts from Foreign Contemporaries

Cement-Covered Wood Poles.—According to Mr. M. Kastler, in the *Schweizerische Elektrotechnische Zeitschrift*, wooden poles—completely covered with a 1.5-in. to 2-in. layer of cement—have been tried and experimented with for the last three years. During this time they have proved entirely satisfactory, and it is hoped that they will be as durable as well-kept iron poles, over which they have the advantage of cheapness. The wooden pole is first surrounded by a wire netting supported from the pole by suitable iron brackets and iron bars. After this has been done the whole of the pole is covered with cement to the thickness mentioned. Such cement-covered wooden poles, in lengths of 39 ft., 42.5 ft. and 46 ft., have recently been employed by the Zurich electricity works. Before adoption some tests were made on a pole 12 meters (39 ft. 4 in.) long, having a diameter of 7-9 in. at the top and 12.4 in. at the base. The length of pole embedded in the ground was 1.6 meters (5 ft. 3 in.), and the pole was subjected to a pull at a point 10.2 meters (33 ft. 5 in.) above the ground, the force being gradually increased until the pole broke. This took place when the pull reached 1,068 kg. (2,370 lb.), and it was observed that the deflections were very nearly proportioned to the force applied up to the moment of breakage. For a force of 838 kg. (1,860 lb.), for instance, the deflection was 89 cm. (2 ft. 11 in.).

Curious Lightning Discharge Effects.—E. L. Ingram communicates to the London *Electrician* particulars concerning the curious and surprising effects of a lightning discharge in Bournemouth on March 15. At 4.30 p. m. on this date a flash of lightning struck a chimney of a house in the Richmont park road, shattered the chimney-stack and got on to the wires of the electric lighting installation. This installation is connected to the Electricity Supply Company's distributing mains, which are triple-concentric, lead-sheathed cables drawn into stoneware ducts. The cables are arranged as usual with the outer conductor neutral, and with 400 volts between the "inner" and "intermediate," the supply to consumers being at 200 volts. The neutral conductor is dead earthed at the transformer chamber, 780 yds. from the house struck, and the lead sheathing of the cables is dead-earthed in each draw box. The installation struck is connected between the inner and neutral conductors. The discharge appears to have found its way to earth through the neutral earth at the transformer chamber, in its course blowing all the distributing and main fuses of the installation struck, shattering the porcelain covers with such violence that one piece of porcelain broke a window some yards away, and blowing the cast-iron service fuse box to pieces. The meter, connected on the pressure or inner main, was burned out, and the metal cover twisted out of shape, while the incandescent lamps were curiously affected. In one case a 16-c.p. lamp, hanging by a length of silk "flex." from the ceiling, had three small holes about ¼ in. diameter burned through the glass close to the collar, the lamp globe not being burst, but the glass being very much blackened all over the inside. In three lamps of this installation the filaments were broken into short lengths and projected against the glass with such force that many of the pieces adhered to the glass and cannot be shaken off. All other installations within a radius of 430 yds., both on the inner and intermediate sides of the distribution system, had one or more lamps affected in the same way, but in no case were all the lamps of an installation damaged. In one house, 95 yds. away, connected on the opposite side of the three-wire system to the one struck, a porcelain fuse fitting was broken. There is no sign of the lightning having pierced the insulation between the conductors of the triple-concentric cable or of having jumped across in any joint box, and the insulation remains high. Nor was there any interruption of the supply by the blowing of transformer or distributing cable fuses. No shunt windings of meters were damaged except that in the house struck. There were no lamps switched on at the time in any of the installations affected.

Prevention of Excessive Pressure Rises.—The London *Electrician* describes two new devices for preventing excessive pressure rises in alternating-current systems, according to recent British patent specifications. The first is a method of the Lahmeyer Company. When machines are switched in or out, disruptive discharges may easily occur, and this principally happens in the coils or parts of conductors which are nearest to the current-supplying mains. To remove this dangerous pressure from the machine, the first coil which shows the largest increase of voltage is connected in series with a choking coil which chokes under normal working conditions the same amount of voltage as every armature coil. This action of the self-induction can be explained as follows: When the self-induction is not switched in, the coils, or parts of conductors nearest to the supply main, exert a choking action

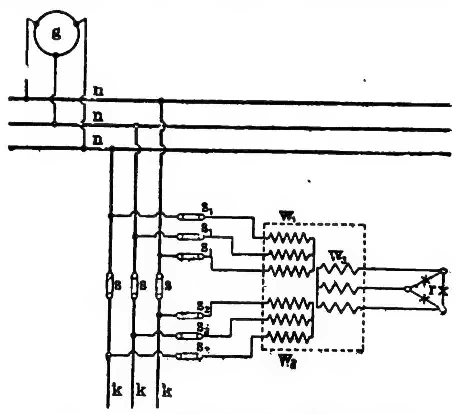

FIG. 1.—DIAGRAM OF CONNECTIONS.

when the current is turned on, so that the whole amount of excessive pressure is, so to speak, concentrated in these first portions of the coils. If, however, self-induction be switched in series with the machine, this self-induction takes up the excess of voltage. The self-induction coil can easily be so insulated that a disruptive discharge cannot occur therein. The choking coil may be short-circuited by another movement of the switch after the starting has been effected. A single choking coil may be used for several machines, this single-choking coil being switched in only

when a machine is switched in or out. The second method has been devised by Siemens Brothers & Co., and is shown in Fig. 1. *g* represents a three-phase current generator, and *n* are the network conductors, from which the cables, *k*, are branched by means of the switches, *s*. The auxiliary appliance consists of a transformer with three windings, of which w_1 and w_2 have the same number of turns, and are connected in the same direction by means of switches, s_1, s_2, respectively, before and after the main switches, *s*, to the cables, *k*. The third winding, w_3, of the transformer, on the other hand, which is advantageously arranged for low pressures, is connected to a non-inductive loading resistance, *r*, of suitable value. Assuming, in the first instance, that the winding, w_3, is open, but that all the switches are closed, then only the magnetizing current of the transformer will flow in the equal windings, w_1, w_2. As regards the conditions of magnetization, nothing will be altered if the winding, w_3, be connected up with the resistance, *r*. Practically the same pressure of the connecting points, w_1, w_2, will still be maintained if the switches, *s* (which are to be considered as combined to form a three-pole switch) are opened; in consequence, no sparks can be formed at the switches, and no oscillations can be produced in the cables. In the same way dangerous oscillation in the cables will be prevented, if the switches, s_1, now be opened, because there are produced at these switches sparks, the extent of which depends upon the resistance, *r*. Such sparks, as is known, allow of no rapid oscillations, in contradistinction to the charging sparks produced on the switching in of unloaded cables. The loading resistance, therefore, acts as a damper of oscillations. The arrangement, which can, of course, be applied to networks having any number of phases, will be as follows: If the unloaded cables, *k*, are to be separated from the network, *n*, then, in the first instance, the switches, s_1, s_2, of the auxiliary are closed, one after the other; the switches, *s*, are then opened and the direct connection between the cables, *k*, and the network conductors, *n*, thereby broken; the switches, s_1, are then opened, whereby the cables, *k*, are deprived of their pressure and by finally opening the switches, s_2, the cables are separated from the auxiliary appliance. When connecting unloaded cables, *k*, to the network, *n*, the switches have to be manipulated in the reverse order, by first closing s_2, then s_1 and by finally closing *s*. When the cables are connected to the mains direct, the switches, s_1 and s_2, are opened one after the other and the auxiliary appliance thereby disconnected. The auxiliary appliance, described above, is also very suitable for testing cables under pressure. In this case the main switches, *s*, would be open or entirely dispensed with. If a higher pressure than that of the existing network pressure is to be used for the testing, then the translation ratio of the windings, w_1 and w_2 instead of being 1 to 1, is made to correspond with the intended testing pressure.

New Positive Clutch.—*The Engineer* of London describes the form of clutch shown by Fig. 2, which has been designed with a view to meeting conditions in which the ordinary friction clutch is not applicable, and where, on the other hand, the older claw-clutch is too violent in its action. The illustration shows the clutch applied to a V-grooved pulley, a longitudinal section through the shaft, a section on the line *X X* being given. The clutch is, of course, equally applicable to a flat pulley or a geared wheel. The construction is as follows: The pulley (or gear wheel), *A*, revolves loosely on the boss, *B*, which is keyed to the shaft of the machine to be driven, and forms the body or main part of the clutch proper. The part, *B*, is provided with pawls, *C*, which slide in slots, as shown. Revolving loosely also round *B* is the ring, *R*, which is provided with recesses, *E*, to receive the pawls, *C*. The ring, *R*, fits into a circular rebate on the pulley, *A*, and has, formed on it, two projecting portions, in which are the recesses, *E*. These projections also form the driving-arms of the clutch, by which the power is transferred to the pulley through the medium of the volute springs, *V*. It will be seen that these springs at their larger ends fit into recesses in the pulley, *A*, and therefore do not cause friction by rubbing on the clutch-ring. The outer extremities of the pawls are chamfered, and a slight additional recess, shown at *F*, is made in the clutch-ring. This recess not only assists the engagement of the clutch, and permits it to drive in either direction, but also enables either part to overrun the other, or run free, and materially assists the clutch to pick up its work. The pawls, *C*, are operated by the toggle-arms, *T*, and the sleeve, *J*; the latter sliding on a feather-key on the shaft. The sleeve is acted on by the collar, *K*, and the pawls are kept up to their work by the spring, *S*, which acts against the fixed collar, *M*, secured to the body of the clutch, *B*, while the pulley receiving the power is retained in place by the lock-nuts, *D*. A dust-cap, *H*, secured by screws tapped into the body of the clutch, is fitted as shown. This cap is preferably made in halves, and is recessed to fit a corresponding projection on *A*, thus excluding dust and dirt when working in exposed positions. A ball-bearing may be fitted to *A* if desired. One advantage claimed for the clutch is the absence of end-thrust when it is in operation. The clutch can also be laid bare for examination or repairs by simply removing the dust-cap, *H*. This clutch seems well adapted for light machinery.

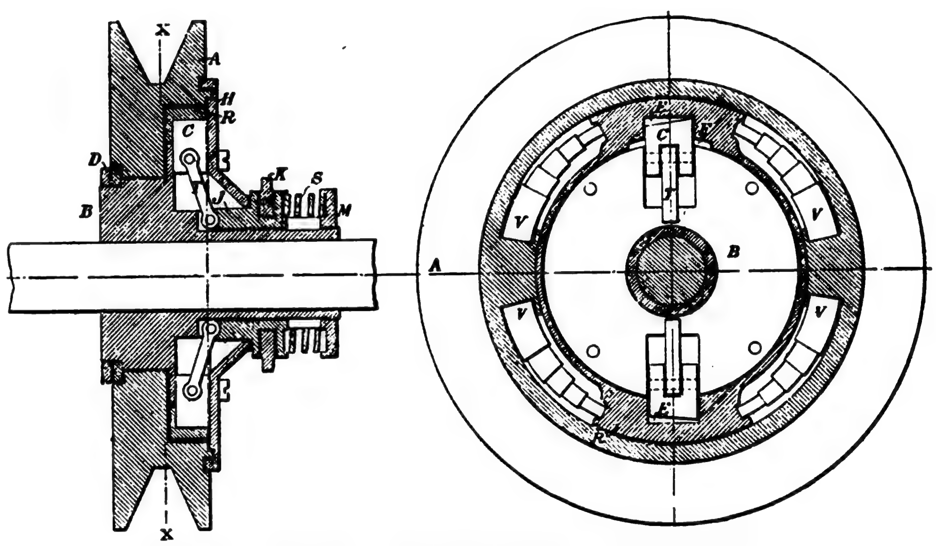

FIG. 2.—SECTIONAL SIDE AND END ELEVATION OF CLUTCH.

Steam Engine Research.—The first report of the Steam Engine Research Committee which was constituted at the instance of the late Mr. Bryan Donkin to investigate and carry out research upon the initial condensation in steam engine cylinders, was read by Prof. D. S. Capper before the British Institution of Mechanical Engineers recently. For the purposes of investigation a special engine was erected in the Engineering Laboratory at King's College. The engine was a horizontal compound engine, with cylinders 6½ ins. and 11¼ ins. in diameter by 14 ins. stroke. The cylinders are side by side, and the connecting rods drive cranks placed at right angles. Each cylinder is separately jacketed on the barrels and the ends, the supply and drain from the ends being separate from that for the barrel. Each cylinder is fitted with a Meyer expansion-valve adjustable by hand, so that the cut-off can be separately varied between one-quarter and five-eighths of the stroke. By grid valves on admission and exhaust sides, either cylinder can be arranged as a simple engine, and by blocking either of the Meyer plates the engine can be made single acting. In any of its varied adjustments the engine is as nearly as possible an ordinary commercial engine, clearance volumes and contact surfaces being kept as small as possible. The clearance volumes for the high-pressure cylinder are 0.025 cu. ft. at the front and 0.033 at the back; and for the low-pressure cylinder 0.053 cu. ft. at the front and 0.056 at the back. On the trials the low-pressure cylinder was not in use, the engine being run as a single-cylinder engine exhausting into a condenser, with the vacuum reduced to

2 in. to 3 in. of mercury. In this way the back pressure in the cylinder was kept constantly at atmospheric pressure. The volume swept through by the high-pressure piston is 0.269 cu. ft. at the back end and 0.254 at the front, after deducting the volume of the 1½-in. diameter piston rod. The clearance space is therefore 12.4 per cent. of the cylinder volume at the back and 9.8 per cent. at the front end. The flywheel is 5 ft. in diameter and water cooled. To ensure steady running at slow speeds, a second flywheel, 7 ft. in diameter, was provided and fitted in halves, so that at speeds above 100 revolutions it could be readily removed. But after the preliminary trials the larger flywheel was found unnecessary and was removed, as, within the range of speeds required, the engine ran perfectly steady without it.

The committee decided that the first series of trials should be made with the engine arranged as a single-cylinder, high-pressure engine, non-condensing jacketed, the second series being a repetition of the first series, but without jackets. After a careful study of previous experiments it was further determined that the variables should be temperature and speed, cut-off and all other conditions being kept constant. Temperatures of 245° F., 280° F., 315° F. and 350° F. were chosen, so as to give equal intervals between successive trials of the series. These temperatures correspond to about 27 lb., 49 lb., 84 lb. and 135 lb. per square inch absolute, respectively, at the engine steam chest. The chosen speeds were 50, 100, 150, 200 and 250 r.p.m., corresponding to piston speeds of about 117 ft., 334 ft., 350 ft., 467 ft. and 584 ft. per minute, respectively. For reasons given below it was not found possible to adhere absolutely to these speeds and temperatures.

A large number of preliminary trials were made to determine the best cut-off, exact speeds and temperatures which could be accomplished with the plant, and to find the best methods of adjusting and working the measuring apparatus, etc. It was found that it was impossible to extend the range of speeds to the lowest limit of the engine—namely, 25 r.p.m.—without interfering with the upper limit, and it was likewise found that at the lowest temperature and pressure the auxiliary pumps could not be got to work. At the upper limit of pressure and lower limit of speed, and at the lower limit of pressure and upper limit of speed, trouble was found in keeping the conditions quite steady. After numerous attempts it was finally found necessary to work the boiler at a slightly higher pressure than that actually required, and to get the exact and steady temperature in the steam chest by slight throttling at the engine stop valve.

At the lowest temperature of the series, and in one or two other cases, this throttling was sufficient to cause superheating. The cut-off which was required to obtain the largest range was found to be three-eighths of the stroke, and this was adhered to throughout both series.

It is dangerous to draw conclusions of too general and sweeping a character from experiments upon one type of engine under one set of conditions, but it may fairly be claimed that the ground covered by this report has never previously been surveyed with an engine showing more consistent and definite results, nor under conditions which enabled so detailed an analysis of the results to be made. The points which have been elucidated may be summarized as follows:

First, leakage through the slide valve has been quantitatively determined under defined conditions, and has been shown to be nearly independent of speed of sliding surface and proportional to difference of pressure between the two sides of the valve. Further, it has been shown that the assumption that the leakage is inversely as the overlap of the valve is at least in the main well founded. And, further, that with well-fitted valves the leakage may amount to over 20 per cent. of the steam entering the cylinder and is rarely less than 4 per cent.

Second, it has been shown that for an unjacketed engine with a given ratio of expansion initial condensation, expressed as a percentage of the steam in the cylinder, *diminishes* with increase of initial temperature, while the total condensation per stroke *increases* with such temperature increase. This, though suggested, had never previously been demonstrated with clearness, as if leakage is not allowed for, the results are obscured and even reversed, and the conclusions arrived at without leakage allowance are therefore unreliable.

Third, it appears from the results here obtained that the re-evaporation for a given ratio of expansion is as great and sometimes greater without jackets than with them. This shows very clearly that the regenerative action of the cylinder walls with a given ratio of expansion is largely independent of their mean temperature. No quantitative analysis of re-evaporation is possible where leakage is not taken into account, as without the necessary allowance results would be largely illusory.

Fourth, it is possible from the results obtained to show the temperature when for any speed of revolution with a given rate of expansion the jackets will become unnecessary or wasteful. If the heat units per indicated horse-power per minute required by the unjacketed engine for each speed of the series be plotted either on an initial pressure or a mean effective pressure base the points for each speed will be found to lie on four curves, which become closer and closer to one another as the speed increases, and all converge to a point as pressure or temperature increases. If the heat consumption for the jacketed series be likewise plotted, it will be found that the points for the different speeds at each pressure lie irregularly round a point, their exact position being determined by the accidentally slight variations of the conditions of each trial.

A fair curve through the means of these points will lie below the corresponding curves for the unjacketed trials, but if the heat absorbed in the jackets be included the resultant curve cuts the unjacketed curves at points which for each speed indicate the temperature and pressure at which the jackets cease to be economical. Such curves are shown on Figs. 3 and 4. It will be seen that the full black line, which is the resultant mean for the jacketed trials, cuts both the 250 and the 200-revolution unjacketed curves within the temperatures and pressures included within the scope of the present experiments, and the temperatures and pressures where the 150, 100, and even the 50-revolution curves would cut, can very closely be predicted. This is the first time that an exact determination for a given engine and ratio of expansion of this point has been diagrammatically shown.

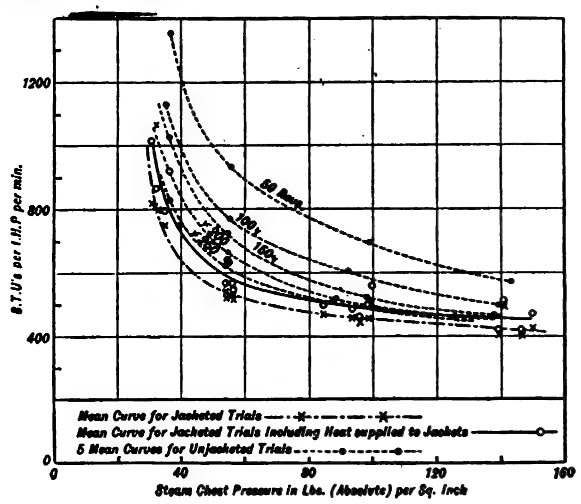

FIG. 3.

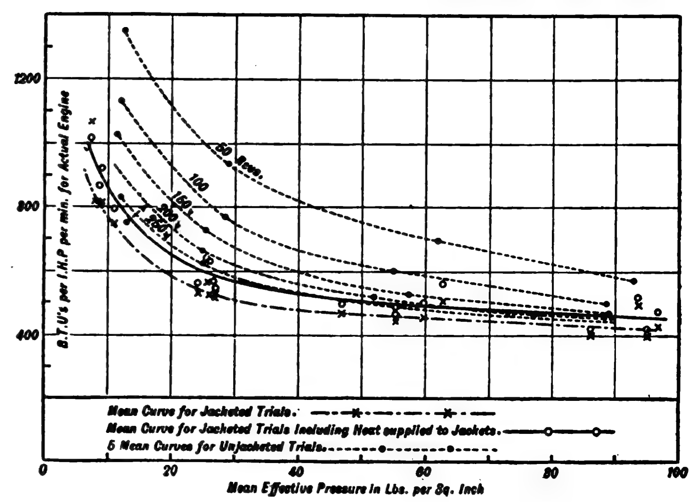

FIG. 4.

Diesel Oil Engine.—*The Engineer,* of London, describes a British-built Diesel oil engine made by the Mirrlees-Watson Company, of Glasgow. The company met with many difficulties in its first engine, which was in some respects a failure; but after waiting a number of years material progress had been made, and it constructed another. In this case the size selected was 35 brake horse-power, single cylinder—the diameter of the cylinder being 11¾ in., stroke 18 in., speed 190 r.p.m. This engine, which embodied the various improvements which had been made up to that time, was started in the early part of 1903, and was put through a series of brake tests and reliability trials, which it passed successfully, and it was decided to install it as part of the works plant and treat it in every way as an ordinary engine. It was therefore arranged that the engine should drive a load of a very variable character, such as wood-working machinery, cranes, etc., this being the character of load which would try it most severely. One of the changes embodied in this engine was in connection with the air compressor. The first engine made gave trouble owing to the high temperature of the air in the air compressor; to overcome this the German company compressed the air in two stages in a very ingenious manner, advantage being taken of the fact that air only is compressed in the main cylinder during the compression stroke. It was arranged to draw from the main cylinder air compressed to about 150 lb. pressure. For this purpose the overflow valve was placed in the cylinder cover, and opened momentarily during the compression stroke, when the compression in the cylinder was about that named. The air passed out of the cylinder to a cooler, and from there was delivered to an air pump of small diameter. By this arrangement the main cylinder and the small pump formed a two-stage compressor, with an inter-cooler between the stages. This got over the trouble experienced with the compressor valves when using a single-stage compressor, as in the engine constructed in 1897, and it worked admirably when using clean oils, such as are readily obtainable in Germany. The company, however, was anxious that the engine should be entirely suitable for using crude fuel oil, such as Texas crude petroleum. After some months of regular working with crude oil, it was found that a brown deposit formed on the air-compressor valves. Experiments were, therefore, carried out to discover the cause of this deposit, and it was found that although the combustion was perfect, and the exhaust practically colorless and odorless, a fine brown dust, persumably the ash of the heavier constituents of the fuel oil, was deposited in the combustion chamber; a little of this became mingled with the air passed to the air compressor. The amount of this dust was extremely slight per stroke, but became, after a few months of working, appreciable and sufficient to affect the tightness of the compressor valves, unless these were cleaned regularly. To obviate this frequent cleaning of valves—the only

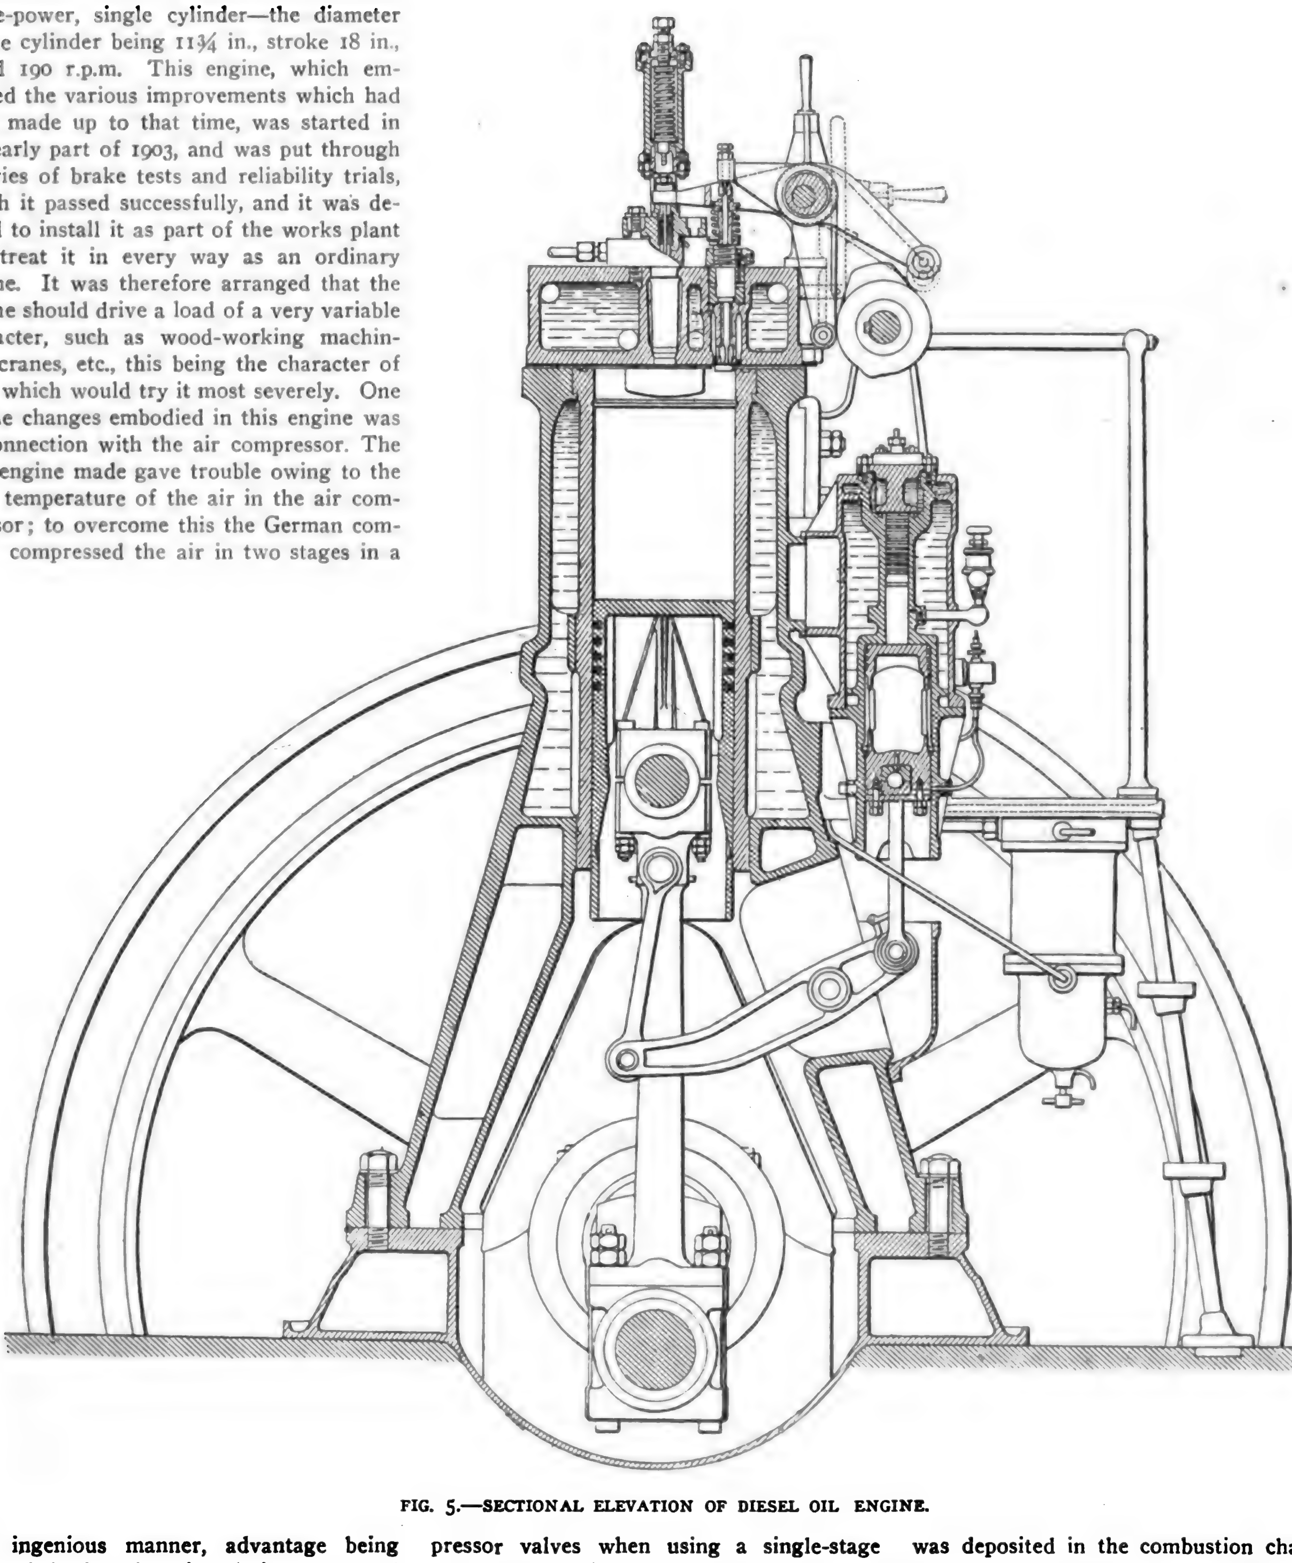

FIG. 5.—SECTIONAL ELEVATION OF DIESEL OIL ENGINE.

difficulty in the engine—an entirely independent two-stage air compressor fitted with efficient cooling arrangements was

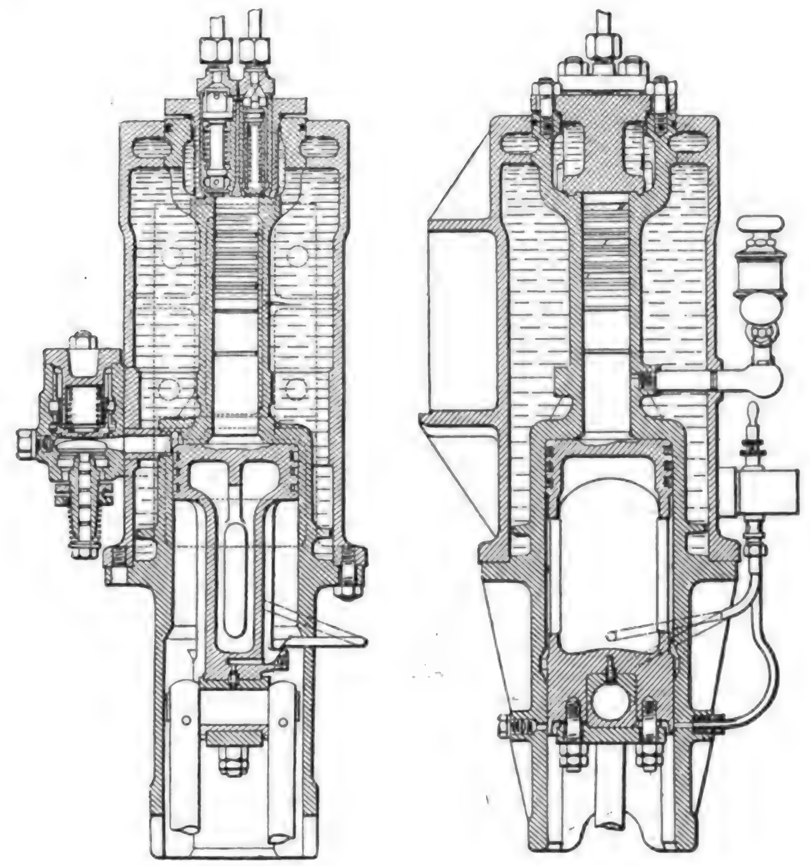

FIG. 6.—SECTIONAL VIEWS OF TWO-STAGE COMPRESSOR.

constructed. Air was supplied from this compressor, and it was found that by this means the difficulty just described was overcome. A second engine was then made and fitted with a two-stage compressor compactly arranged on the frame of the engine, as shown by Fig. 6, in which the two-stage compressor is shown to a larger scale, and in designing which great attention was given to the valves and to the cooling arrangements.

Overhead Transmission Lines.—The London *Electrician* contains M. Semenza's paper, read before the Italian Electrical Society on "Overhead Transmission Lines," in which the author deals especially with the construction of the poles. The author recommends iron posts and describes what he considers a very great improvement in the construction of metallic supports, consisting in making them elastic. In a straight track, and with equal spans, the only force acting on the supports, apart from the weight of the wire, is the transverse wind pressure. It is, therefore, unnecessary to make them withstand a longitudinal stress, and they need only be designed for a transverse stress. As is seen from Fig. 7, they consist of two parallel uprights of channel iron about 2 meters apart trussed together with angle irons. Should the wires ever get broken, the supports by their elasticity will bend in the longitudinal direction, and this deflection will instantly diminish the tension. In the highly improbable case of the breakage of all the wires in one span, it is found that the first support beyond the break will deflect considerably, but as this deflection diminishes the length of each successive span, and, therefore, the tension of the wires, the second support will be deflected, but to a less extent. The farther

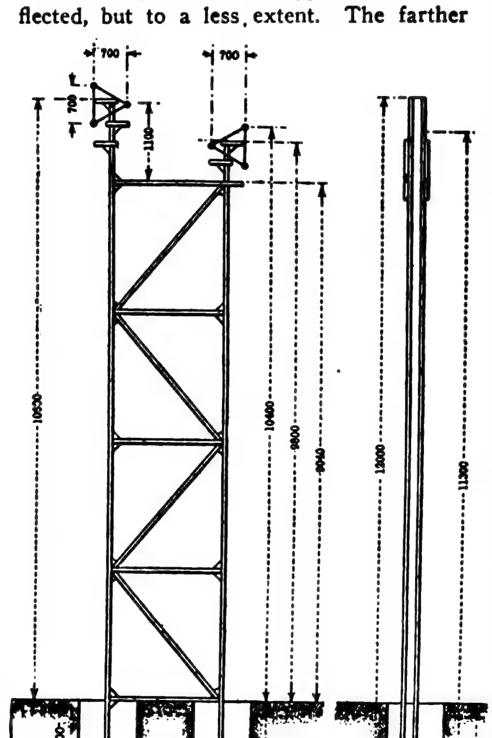

FIG. 7.—STRUCTURE FOR TRANSMISSION LINES.

supports will also deflect, but will always to a lesser degree, and by calculation it is found that should the tension be entirely removed from one side the resulting stress would not exceed half that on a rigid support. Thus he arrives at "the apparent paradox that the weakness of the support is a factor of its resistance to breaking." The author urges the great importance of the choice of proper insulators.

Economical Supply of Light Load.—There are quite a number of small and medium-sized central stations which supply a lighting and traction load, and these require besides the battery for the traction system, an additional battery for the lighting system after midnight, especially if the load is so light that the operation of a generator would be uneconomical. Where the lighting supply is alternating a small machine must be kept running to supply this load. B. Jacobi describes, in a recent number of the *Elektrotechnische Zeitschrift*, an arrangement which has been in operation for a number of years and proved satisfactory and economical. This is shown diagrammatically by Fig. 8 herewith. The station supplies high-tension, three-phase current for light and power and 500-volt direct current for the railway system. This latter current is supplied from the rotary, *R*, which is supplied from the generator, *G*, through the transformer, *T*. After midnight, or when the railway system shuts down, the traction battery, *P*, supplies the lighting load. In the diagram, *Z* represents a booster, *A* a starter, *N* a shunt regulator, *V* a voltmeter, *SV* a synchronizing voltmeter, *MT* a switchboard transformer, and *Sp* the supply network. During the day *R* runs in parallel with *P* and supplies the traction current. *Z*, which is directly coupled with *R*, runs unloaded; *EA* is open and *ZU* is in its middle position; *EU* is closed upwards in the diagram and connects the positive pole of the battery with the bus-bar. For charging, while *R* is still running, *A* is short-circuited, *EU* is thrown to the downward position in the diagram, and *ZU* is closed upward. After adjusting the correct booster voltage by means of N_2, *EA* is closed and the charging begins. The voltage of *Z* is added in the usual way to that of *R* and is properly adjusted by means of N_2 until the charging is finished. After setting *R* and *Z* at rest it is intended to let *R* supply the lighting current for the night hours. All switches are open, as is also *A*. Now *EU* and *ZU* are connected downward. By means of N_1 strong excitation of *R* is produced, and by means of N_2 medium excitation of *Z*. Then *EA* is closed and by means of *A* the set *RZ* is slowly started with current from *P*. As soon as *A* is short-circuited, DA_2 is closed, VU_2 is connected to MT_1 and at V_2 the voltage at the high-tension terminals of *T* is read. By means of N_2 adjustment is made until V_2 shows the correct supply voltage. It is still necessary to connect *R* in parallel with the running machine, *G*. For this purpose N_1 is used. Since *R*, operated as a direct-current motor from P_1, behaves like a shunt motor, a change of the field produces a variation of speed. When *SV* shows synchronism, *DA* is closed and *G* is finally brought to rest and disconnected. The lighting current is now supplied from *P*. It will be seen that by means

of ZU the polarity of Z has been reversed; that is, the negative pole of Z is connected with the positive pole of P. By this means the decrease of the battery e.m.f. during discharge can be counteracted by Z, so that at the terminals of R and T the voltage is held constant.[1] In actual operation it is found that although P discharges, the voltage at the high-tension terminals of T is automatically maintained constant. The explanation is that R and Z are excited from the battery so that when the voltage of P decreases, the excitation of R is decreased and the speed of R increases so that the e.m.f. furnished by Z also increases, although its field is weakened. Thus the voltage at the terminals of R remains approximately constant, while the speed and frequency increase. Should the frequency become 10 per cent higher than the normal value, it is necessary only to adjust N_1 and N_2 so as to increase both currents, whereby the speed of R is reduced, while the voltage of Z which is thereby diminished, is again raised. This adjustment may be made once an hour.

Some Recent Electrical Patents

Armature Winding and Commutators for Alternating-Current Motors.—In order to avoid the trouble due to the currents induced by the alternating flux in the armature coils short-circuited by the brushes of a commutator-type, alternating-current motor, Mr. Max Deri, of Vienna, Austria, proposes to equip the armature with two distinct windings intermeshed mechanically around the core, of course, and two distinct sets of commutator bars and brushes. The brushes are made too thin to touch two commutator bars simultaneously, so that when a brush leaves a bar it opens the circuit of the corresponding winding. The brushes are arranged so that when one winding is thus open-circuited the other is in connection with its brushes, so that the armature as a whole is never open-circuited by the brushes—the armature activity is merely shifted from one winding to the other. The diagrams, Fig. 1, illustrate this arrangement as applied to a repulsion motor, but the inventor states that it is equally applicable to a series motor or to one in which the armature takes current from a constant-potential source. Patent No. 786,010.

Arc Lamp.—In most arc lamps, both shunt wound and differentially-wound, the shunt magnet coil remains connected to the lamp terminals under all conditions, so that when the lamp becomes extinguished accidentally or by any means other than the manipulation of the cut-off switch, the shunt coil remains in the main circuit. The objections to this are obvious, although not usually very serious. In order to eliminate the disadvantage entirely, the mechanism shown in Fig. 2 has been devised by Mr. Bruno Jackisch, of Charlottenburg, Germany. The engraving illustrates diagrammatically a differential lamp, the shunt coil being at *n* and the series coil at *h*. The solenoid plunger, *s*, is hollow and carries with it in its movements the carbon sheath, to the lower end of which is attached the clutch member. The plunger carries at its lower end a vertical extension, *f*, to which one terminal of the shunt magnet coil is connected. Under normal operating conditions this extension finger is in contact (at *a*) with the lower end of a slider, *c*, which is connected to the negative terminal of the lamp and therefore completes the

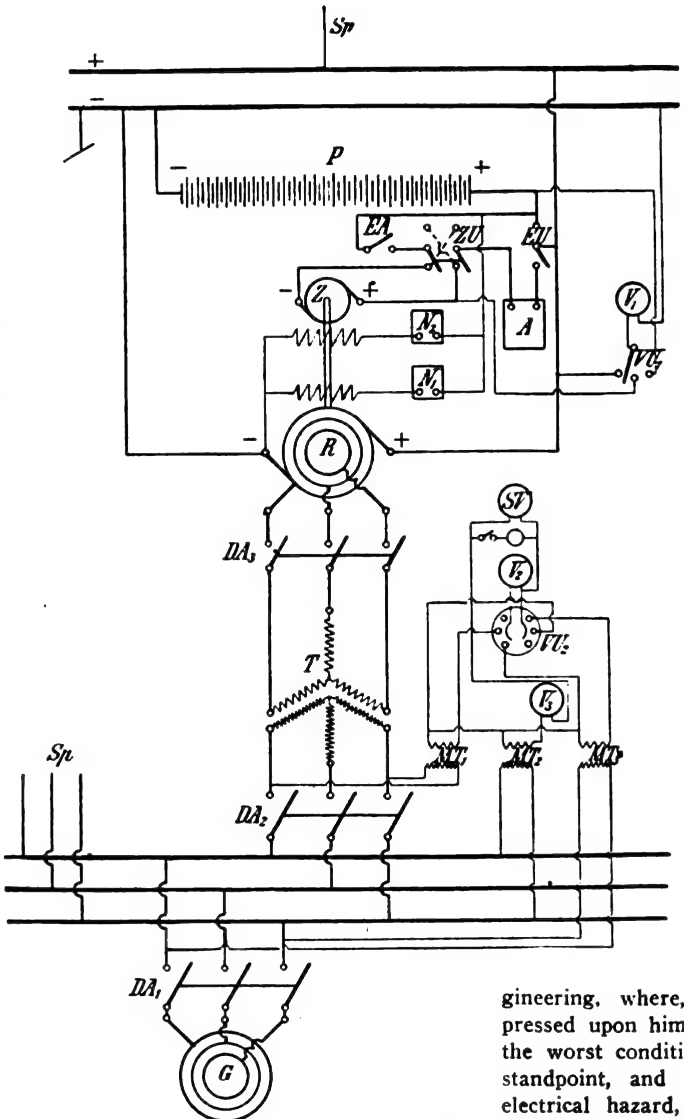

FIG. 8.—ECONOMICAL SUPPLY OF LIGHT LOAD.

circuit of the shunt coil. The slider follows the movements of the plunger within the full operating range, but if the plunger drops far enough to release the carbon entirely, as it does when the arc is extinguished, the head of the slider, *c*, will rest on the mount, *d*, before the plunger reaches its bottom limit of travel, and the finger, *f*, then moves away from the slider and opens the circuit of the shunt magnet coil. This, therefore, is the normal condition whenever the arc is extinguished from any cause whatever. Of course, when the series coil picks up the carbon in starting the lamp, the shunt circuit is closed at *a* before the full length of arc is established. The inventor does not state how this arrangement is to be applied to a simple shunt-wound lamp. Patent No. 787,043.

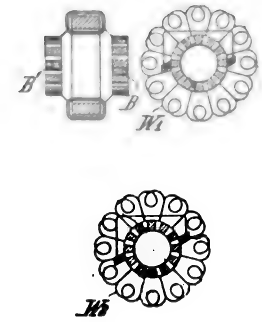

FIG. 1.

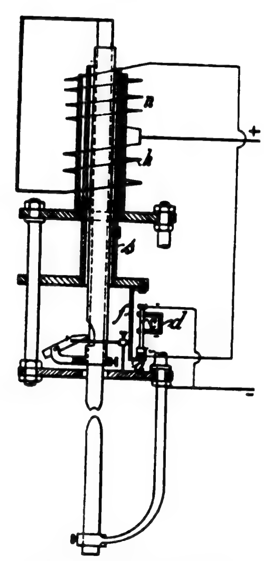

FIG. 2.—ARC LAMP.

Fire Risks in Isolated Plants.

To the Editor, American Electrician:

SIR:—The initial sentence of your editorial in the February number on "Fire Risks in Isolated Plants," has struck a responsive chord in the writer, whose business, while in no way connected with fire insurance or the underwriter's board, takes him through many power houses and related properties, both large and small, in relation to questions of fire protection engineering, where, the fact has been impressed upon him that, generally speaking, the worst condition of affairs from a fire standpoint, and especially regarding the electrical hazard, exists in power houses, car barns and electric plants, where it would naturally be assumed that the most attention would be given these features.

The portion of your editorial calling attention to the simple yet highly desirable protective devices which should exist in all such properties is admirable, bearing in mind that sand is most adapted to quenching oil and electric fires, water-pails to more combustible materials, such as exist in the stockroom, extinguishers are most appropriate in locations where it may be necessary to reach a fire not readily accessible with fire pails, such as among the roof structure or where the flames may quickly spread over a considerable area upon which a pail full of water would produce only momentary effect. Of course, chemical extinguishers are desirable in almost all locations, except where exposed to freezing, although their cost may sometimes mitigate

against their being provided among rougher classes of work, or where water pails will probably be satisfactory.

The more important features in fire protective engineering, however, are the defectively arranged and too often inoperative condition of the fire lines, hose and pumps. There seems to be no limitations to the foolish methods and carelessness shown in the installation and maintenance of fire lines and hose equipments. The engineer of an electric plant usually assures the writer that everything relating to the fire protective devices is in perfect order, but an examination or test shows them (it may almost be said in the majority of cases) to be at least wholly inadequate or inoperative, when viewed from a practical viewpoint of the operating requirements. This may be a somewhat broad statement, but the writer, although for many years connected with electrical and civil engineering, has been continually surprised since turning his attention to fire protective matters at the woeful lack of appreciation of the common hazards, and especially those due to electricity, existing among the average industrial and electrical plants throughout the East. The larger question of building design from a fire standpoint should also receive more attention from engineers. A station is not made fireproof merely by the presence of a concrete floor and brick walls, when the roof is of plank on light steel trusses. It is astonishing with what fierceness the insulation on a few ordinary type cables will burn, and what damage can be wrought in a steel roof structure by a fire among a small amount of combustible material. The roofs of many all-steel fireproof car barns have been practically destroyed by the burning of perhaps a portion of one car or some wooden lockers or oil cabinets in the barn. It is, of course, well known that there are monumental and striking examples of the highest development of the art of protection against fire, both regarding proper building construction and adequate protective devices, in many of our large urban electric stations, or in the suburban sub-stations thereof, but in speaking as a whole the electric stations can hardly be said to be even up to the average from a fire standpoint. This may be due to the hurried development of electrical industries and the great amount of work which has been done by engineers with relatively little available capital in many cases, but it is to be hoped that now that electrical enterprises are being promoted upon a conservative and substantial financial basis, that plants will be built or rebuilt upon broader principles and with the proper concern for permanency and stability which can be secured only by careful attention and conformity to the principles of fire protective engineering.

CENTRAL STATION ENGINEERS.

VII.

John A. Britton.

John A. Britton, general manager of the California Gas & Electric Corporation, was born October 9, 1855, in Boston, Mass. When he was 13 years old his parents migrated to San Francisco, Cal. Here he received such education as the public schools afforded and afterward devoted two years to the study of law. His exceptionally active career in the field of public lighting was begun at the early age of 19, when he entered the employ of the gas company in Oakland, Cal. His aptitude for business soon met with the approval of his superiors, for nine years afterward found him secretary of the company. In 1894 he became the company's engineer, and held this post for several years, when he was singled out for further distinction, and in 1900 he was

JOHN A. BRITTON.

elected to the presidency of the company. He also acted as consulting engineer for the Stockton Gas Company, Power Transit & Light Company, and the California Central Gas & Electric Company. Mr. Britton installed the first electric lighting plant in Oakland. This was put in operation in 1882, the capacity being 125 horse-power. The present capacity of the plant is 4000 horse-power. Since 1892, with the exception of the years 1901 to 1903, Mr. Britton was secretary of the Pacific Coast Gas Association, and is at present a member of the Board of Regents of the University of California. As previously stated, Mr. Britton is the general manager of the California Gas & Electric Corporation. This company controls the Sacramento Electric, Gas & Railway Company, the California Central Gas & Electric Company, the Bay Counties Power Company, the Valley Counties Power Company, the Oakland Gas, Light & Heat Company, the Fresno Gas & Electric Light Company, Standard Electric Company of California and its subsidiary companies, the United Gas & Electric Company, the South Yuba Water Company and the Central California Electric Company. The company owns the entire street railway system of Sacramento, Cal., and owns and controls all of the electric light and power transmission lines, gas plants and water rights in Sacramento and vicinity.

NOTES.

Electricity in a New Grocery.—Although the details of the grocery business fall considerably outside the electrical engineer's usual activities, a recent installation in Worcester, Mass., deserves attention in view of its lavish use of electric lighting. The establishment is that of the Central Grocery Company, opened very recently. The store consists of a large salesroom on the street floor, a reception room at one end for the use of customers, a general office and private offices. There are also shipping and storage rooms close at hand. The striking feature however, is the use of "Meridian" lamps in clusters of five in the main store. These are of the 120-watt type and they are covered by frosted shades. In the main store, which consists of a room about 75 feet long by 25 feet wide, and a bay 20 feet by 35 feet, approximately, are no less than 90 "Meridian" lamps, while over the doorway is a cluster of five more, with a cluster of the same number in each of the two show windows. The reception room contains a cluster which partly illuminates the main store, and there are two single lamps in the private offices. The total number of such lamps is 112, according to a hasty visit made soon after the store opened. In various places 16-c.p. incandescents are also employed for lighting desks, etc. The resulting illumination is soft and very brilliant, and as an advertisement of a new establishment it is exceedingly effective. At the same time it would seem that the use of clear globes would have been better practice, for the lighting could then have been done with 40 or 50 per cent of the present equipment, and quite as effectively. The grouping of globes would give the even illumination required, and the suspension of the lighting units near the ceiling obviates any difficulty in regard to the eyes of customers. From the engineering standpoint the illumination is admirable in the whole, but inefficient in the details. The contractor for the installation apparently carried the idea of translucent globe effects too far. Two 500-volt motors are in use in the store. One is a ½-h.p. Holtzer-Cabot machine driving the cash carrier system; the other is a 2-h.p. Westinghouse motor direct-connected to a coffee mill.

Summer School for Artisans.—The University of Wisconsin, Madison, Wis., announces the opening of the fifth session of its annual Summer School for Artisans on June 26. The school closes on August 4. The courses cover the following subjects: "Engines and Boilers," "Applied Electricity," "Mechanical Drawing and Machine Design," "Materials of Construction, Fuels and Lubricants" and shop work.

Electric Lighting Costs in Massachusetts.—A writer in a New England paper states that an examination of the reports of the Massachusetts Board of Gas and Electric Light Commissioners for the five years ending with 1903 developed the fact that the cost of electric lighting in municipal plants during that period increased in two-thirds of the cases, while in a total of 63 cases of lighting by private plants, only seven had increased their prices and the remaining fifty-six showed a decrease.

The Southern Supply and Machinery Dealers' Association held a conspicuously successful convention April 25 to 28, inclusive, at Savannah, Ga. The delegates discussed freely a number of practical and important topics, and enjoyed more than the usual offering of entertainment features. The active membership now includes dealers in Alabama, Arkansas, Florida, Maryland, Missouri, North Carolina, South Carolina, Tennessee, Texas, Virginia and West Virginia, and the list of honorary members contains the names of manufacturers all over the country.

An Induction Motor in a Direct-Current Plant.—An interesting application of an induction motor in a plant equipped with direct-current apparatus occurs at the East Moline shops of the Chicago, Rock Island & Pacific Railway. The main generating equipment of the power house comprises 250-volt, direct-current dynamos, which supply current to the motor-driven tools throughout the establishment. The pumping station, however, is about two miles away on the banks of the Mississippi River, and the pumping machinery is driven by a 50-h.p., three-phase, 220-volt induction motor. Current for this motor is supplied from a line fed by an inverted rotary converter. Thus by the use of this type of motor the advantages of a higher voltage are realized, besides the low cost of maintenance characteristic of induction machines.

Stevens Institute Affairs.—The authorities of Stevens Institute of Technology have taken up vigorously the task of raising the additional $100,000 required to render available the $100,000 conditionally donated by Mr. Andrew Carnegie and President Humphreys ($50,000 each) at the recent dinner of the Stevens alumni. It is expected that the alumni will heartily cooperate by contributing and also by awakening the interest of their friends. Through the generosity of the Stevens family, the Institute has been enabled to secure for athletic grounds, campus and building purposes that part of the historic "Castle Point" estate at Hoboken most advantageous for such uses. In the near future this land will be graded and properly laid out, if the hopes of the Institute management are realized.

Reduction in New York Telephone Rates.—The New York Telephone Company announces a very comprehensive revision of its rates to take effect May 1. The principal changes in the schedules are shown by the following tables:

RESIDENCE SERVICE:

Number of Messages.	Direct line. Old rate.	Direct line. New rate.	Party line. Old rate.	Party line. New rate.
600	$66	$54	$54	$45
800	78	63	66	54
1000	90	72	78	63
1200	102	81	90	72
1800	138	105		
2400	165	129		

BUSINESS PARTY LINES:

Messages.	Old rate.	New rate.
800	$75	$69
1000	87	78
1200	99	87
1500	117	99
1800	135	111
2100	153	123

The toll rates have also been revised, but the new rates go into effect June 1 instead of May 1. They are as follows:

	From Manhattan.		From Bronx.	
	Subscriber's rate.	Pay station rate.	Subscriber's rate.	Pay station rate.
Astoria	$.10	$.15	$.15	$.20
Bath Beach	.15	.20	.20	.25
Bronx	.10	.15	—	—
Brooklyn	.10	.15	.15	.20
Coney Island	.15	.20	.20	.25
Far Rockaway	.20	.25	.20	.25
Flushing	.15	.20	.15	.20
Jamaica	.15	.20	.15	.20
Manhattan	—	—	.10	.15
New Dorp	.15	.20	.20	.25
Newtown	.10	.15	.15	.20
Tompkinsville	.15	.20	.20	.25
Tottenville	.20	.25	.20	.25

International Prize Competition.—An international competition for prizes for various appliances has been announced by the Association of Italian Manufacturers, the list of appliances and prizes being as follows:

A.—A gold medal and 8000 lire for a new appliance for preventing accidents arising from contacts between primary and secondary windings in alternate-current transformers. The appliance must fulfill the condition that no disturbance in the action of the transformer must arise in case of atmospheric discharges or abnormal increase of potential.

B.—A gold medal and 1000 lire for a novel system of hand crane or winch fitted with a simple and practical contrivance to prevent the possibility of the handles revolving during the descent of the load.

C.—A gold medal and 500 lire for a safety appliance to be simple, strong and reliable, to stop trucks automatically on an inclined plane on the hauling rope snapping. The appliance must be adaptable to existing plant.

D.—A gold medal for a system of absorption and collection of the dust produced in sorting and cutting rags by hand without giving rise to draughts detrimental to the health of the workpeople.

E.—A gold medal for a system to carry off by suction the dust generated by carding flax, hemp and jute without detriment to the neighborhood.

F.—A gold medal for a system to prevent the diffusion of dust in lime and cement works.

The conditions of the competition are as follows:

1.—Applications to compete must be sent in not later than July 31, 1905, addressed to the president of the Association of Italian Manufacturers for the Prevention of Accidents in Factories, Foro Bonaparte, 61, Milan.

2.—All appliances entered for competition for the prizes *A, B, C* must be exhibited at the competitor's expense, in such dimensions and conditions as to allow of their being practically tested at the Milan Exhibition of 1906 in such time as may be determined by the Exhibition Committee.

3.—No charge for space will be made to competitors who intend to exhibit their appliances in the space allotted to the association; they must, however, in their applications to compete, state the exact area they require. The acceptance of all applications to compete is optional with the president of the association.

4.—Competitors who elect to exhibit in other sections of the exhibition must allow a notice to be attached to their appliances stating that they form part of the competition founded by the association. They must forward to the association not later than January 1, 1906, a properly executed, detailed drawing of their appliances, which the association will exhibit in its own section.

5.—Competitors for the prizes *D, E* and *F* must have their appliances at work in works in Italy; they must also forward to the association, to be placed in its exhibit, a detailed drawing, a small model and a full description of their appliances.

6.—All appliances presented for competition are the property of competitors; the association will, however, retain the drawings, models and descriptions. All rights connected with the appliances are the exclusive property of their owners, who must, however, take all necessary steps to guarantee their rights.

7.—The association reserves the right to publish, at the close of the exhibition, descriptions and drawings of all the appliances.

8.—A committee appointed by the council of the association will examine all appliances presented for competition. The appliances approved of on principle will be subjected to tests, after which they will be classified according to their merits. The council of the association will award the prizes in accordance with the report of the committee; no appeal from their decisions will be entertained.

ESTABLISHED 1889.

AMERICAN ELECTRICIAN

WITH WHICH IS INCORPORATED

Electrical Industries.

CECIL P. POOLE, Editor.

Issued on the first of each month by the

McGraw Publishing Company

114 Liberty Street, New York.

Philadelphia Office..........929 Chestnut Street
Chicago Office..............Monadnock Building
Cleveland Office.............Cuyahoga Building
London Office, Hastings House, Norfolk St., Strand

Address all business communications to AMERICAN ELECTRICIAN, 114 Liberty Street, New York. Matter intended for publication in the reading columns should be addressed to the editor.

Subscription price, $1 per year, postage prepaid, in the United States, Canada, Mexico and Cuba; $2 in all foreign countries. The date on wrapper shows when subscription expires. Subscribers should give their old as well as their new address when requesting a change in address.

Advertising rates sent on application. Advertisements received for insertion up to the 25th of the month prior to date of publication. Changes in standing advertisements should be received not later than the 15th of the month to insure their insertion in the next issue.

Remittances should be by check, draft, express or postal money order, payable to McGraw Publishing Company.

Entered in the Post Office at New York as second class mail matter.

Vol. XVII. MAY, 1905 No. 5

The AMERICAN ELECTRICIAN has the largest circulation of any electrical journal published. Of this issue, 18,000 copies are printed. The total number of copies printed so far this year is 92,000, or an average of 18,400 per issue.

CONTENTS.

Back Numbers.

Until recently the publishers of this journal have endeavored to keep in stock indefinitely a supply of back numbers, but experience has demonstrated that the trouble involved in keeping separate numbers more than a year old is out of all proportion to the value of the accommodation to subscribers. It has been decided, therefore, to keep separate copies for only twelve months back. Readers desiring copies dating farther back than May, 1904, should order them immediately, as the stock on hand will be disposed of as quickly as possible. Bound volumes will be kept in stock as usual.

Improving the Load Factor of a Central Station.

The operation of an electric power station at or near its rated capacity is recognized as being one of the most important considerations in station economics, and it is particularly advantageous, therefore, to study the load factor under varying conditions of service. Depending on the kind of work performed, the ratio of the average load to the aggregate rating of the machinery differs widely in different cases, but in practically all plants high operating efficiency and the minimizing of unproductive charges require that the equipment shall be well loaded throughout the day's run. With a view to securing this result, station managers are turning their attention more and more toward the increasing of their motor loads and their outputs for advertising purposes, and many of them have made a careful analysis of the hours of operation of different parts of their plants with regard to the demand on those parts respectively.

Having fewer generating units, the small central station cannot be expected to follow the variations in its load as efficiently as a large, or moderately large, station does by varying the number of active units. In many cases, therefore, there is strong temptation to assume that it is not worth while to make any study of the load factor, there being possibly not more than two or three units in the station. There are, however, other factors in the improvement of the load factor besides the mere cutting in and out of generating units. It will usually be found advantageous, for example, where there are only required, say, 500 kilowatts maximum output ability, to install two good-sized units of equal capacity and a smaller unit for taking the minimum load. The relation between this small unit and the other two will depend considerably on the character of the service; in many cases one 100-kw. and two 200-kw. units would be found sufficiently flexible, while in others it might be advisable to use even a 50-kw. unit and to divide the remainder of the output equally between two larger units. This would be a rather extreme case, however. Again, the relative economy of the prime mover at full and partial loads should be carefully considered. It is sometimes better to sacrifice full-load efficiency in order to gain in the partial load performance of an engine; in fact, this is very frequently true in the case of a small central station.

Although the load factor of a station is ordinarily determined by plotting load curves and averaging the results, the easiest method, and one which is quite as satisfactory, is to compare the daily records of a recording watt-hour meter with the capacity of the generator in circuit with which it is connected. Such a meter integrates fluctuations much more accurately than voltmeter and ammeter readings can be plotted under ordinary operating conditions in small stations. It is, of course, necessary to keep an eye on the generator ammeter in order to see that no undue overloads are put on the machine. The load factor should be determined at reasonably short intervals throughout the year. The remedy for a poor load factor will depend entirely on the operating conditions in each case. No general rule is of any value.

Coal Handling in Isolated Plants.

A surprising proportion of the American isolated plants suffer great inconvenience in the matter of coal handling. In many modern buildings even, the location of the power equipment receives only cursory attention from the architect, almost any dark and otherwise useless corner of the subbasement being considered good enough to contain the expensive machinery on which the commercial success of the building depends to a very great extent. In some cases, a handsome engine and generator room is provided, but the boiler plant is stowed away in the darkness, with the coal pile situated beneath the sidewalk at a most inconvenient distance from the firing floor. All such arrangements mean increased operating costs, of course.

In a city isolated plant, such as that in a large hotel or office building, it would seem to be a relatively simple matter to provide for the economical handling of the coal, excepting the few cases in which it is really impracticable to allot a liberal space, even in the sub-basement, to the steam equip-

ment. It is obviously more expensive to deliver coal to an isolated plant than to a central station, owing to the unfavorable location of the former and the relatively small quantity of coal that can be stored, but once the coal is on the ground it should be practicable to dump it by gravity into a bin fairly near the boiler room and situated on a higher level so that it may be drawn through a chute into a barrow or small car in which it may be wheeled to the scales and thence to the firing floor; the resulting economy in time and manual effort would be profitable. The reshoveling of coal should be avoided just as far as possible; a small car running on an inclined track, or a power-operated hoist, or even a simple hand chain hoist, is well worth consideration wherever the cost of firing would otherwise be chargeable largely to the labor of moving coal from the storage bin to the firing floor. This also applies to the removal of ashes.

The Critical Freqdency for Alternating-Current Lighting.

It is undoubtedly the common impression that incandescent lighting at alternating-current frequencies below something like 35 cycles is not practical; in fact, one well-known authority on artificial illumination has stated that in general a 16-c.p. lamp of 100 to 120 volts begins to show the variations of current intensity at 30 cycles or a trifle above, and that at 25 cycles the fluctuations are very troublesome to most eyes. Only two of a considerable number of engineers with whom we have discussed the question expressed any doubt whatever that 25-cycle lighting is impracticable indoors. A little persistent inquiry, however, discloses the fact that the notion as to the uncomfortable effect on the eyes at 25 cycles is based on either hearsay cr a vague impression of having read some account of tests which showed that result. We have been unable thus far to learn of any thorough, impartial test made to determine the downward limit in frequency for incandescent lighting. The station lamps of the Manhattan Elevated Railway are supplied with 25-cycle current, but that is not much of a criterion for the reason that most of the lamps are out of doors, and those that are inside are not used in a class of service that would serve as a standard for general practice. The Buffalo General Electric Company is supplying incandescent lighting from 25-cycle circuits, but reports only "indifferent success." In view of the enormous investment already laid out in 25-cycle generating stations and the expense of putting in frequency changers for incandescent service from such stations, it would seem to be about time for somebody to make a few careful tests to determine once for all whether or not it would be safe for a central station to depend solely on 25-cycle current for incandescent lighting.

Arc lamps, of course, cannot be operated on any such frequency as 25 or 30 cycles. The frequency at which the arc becomes unstable, however, appears to be about as uncertain as the limit for incandescent lighting. It has been said that the fluctuations are discernible at 60 cycles, but it is quite common practice to supply enclosed arcs at that frequency in this country and 50 cycles abroad. Of course, there is no hard-and-fast critical point at which either class of lighting can be said to become generally impractical. With arcs, the length of arc, character of carbons and volume of current affect the behavior of the arc so as to vary the critical value of the frequency, while with incandescents the voltage and efficiency affect the critical point. Since it is practically certain, however, that arc lighting is out of the question at 30 cycles, and 60 cycles has become the standard moderate frequency, the actual low frequency limit for this class of service is not of so much importance as that for incandescent lamps. Some form of frequency changer must inevitably be employed in 25-cycle stations suppying arc lamps.

A Terrible Waste of Coal.

With this heading as its text and in the would-be superior tone that it habitually assumes in discussing technical subjects, *The New York Times* recently took occasion to ignore a few facts and distort a few others in order to create an opportunity to lecture "electricians" on their lack of humility and superabundance of homage-seeking, which exists solely in the imagination of the *Times*. Referring to the well-known low efficiency which characterizes the conversion of the heat energy in coal into luminous energy at the incandescent lamp filament, the writer of the article gives us a grain of credit for not claiming that the incandescent lamp converts into heat more than 4 to 6 per cent. of the energy delivered to it, and then proceeds: "As that loss is only the last of many—on the wires, in the dynamo, in the boiler and in the furnace, to mention only a few of the more important—the best that has been said for the incandescent lamp is that of the energy contained in the coal and converted into heat, it turns ½ of 1 per cent. into light." Then with a patronizing reference to the "more than a few powerful intellects struggling with the problem of getting the energy stored in coal at first hand instead of tenth or twentieth," we are admonished that "Meanwhile, the 'wonder-workers' might be a little more humble." As a half-statement of facts and a specimen of perverted logic this utterance fits in finely with the *Times'* system of technical argument. Incidentally, one might reasonably suppose that in view of the *Times'* record in the way of ludicrous technical blunders and sciolistic dicta a little more humility in its own household would not be unbecoming when a question of mixed thermodynamics and electrical engineering is involved. But reasonable suppositions don't fit the *Times'* case.

Steam Turbine Performance.

It would undoubtedly be of extremely great value to the central station industry at large if those stations which have installed steam turbines would make public the results of economy tests run under actual operating conditions after the apparatus has been in service for a reasonable period—say, six or twelve months. The statement has often been made, by impartial engineers as well as the manufacturers, that a properly designed turbine is inherently capable of maintaining its initial economy after a considerable period of service, and the simplicity of the rubbing surfaces makes this highly probable so far as those surfaces are concerned; but there is no information as to the rapidity of blade deterioration nor as to the effect of such wear on the general economy of the machine. On the face of it, one might reasonably suppose that the wear of blades and vanes would be almost negligible when operated with superheated steam, and that the shop test of a turbine outfit would therefore be a suitable criterion of its performance in the station for quite a respectable period of time. But suppositions are of little value in engineering, especially the commercial side of central station engineering, and a few confirmatory or modifying tests of turbine sets actually in service would be of inestimable value, not only to probable buyers but to the manufacturers themselves.

DESIGN AND CONSTRUCTION OF SMALL DYNAMOS AND MOTORS.

BY CECIL P. POOLE.

Miscellaneous Instructions.

The connections between field windings and terminal blocks and those from brush-holder studs to terminals should invariably be of stranded conductor, heavily insulated with rubber and an external braid. The leads from the field winding may usually be of No. 14 B. & S. gauge, but for machines of 10 kilowatts and over, it will be found more satisfactory to use No. 12 stranded wire on account of the greater ruggedness of the material. The leads from the brush-holder studs should be of sufficient cross-

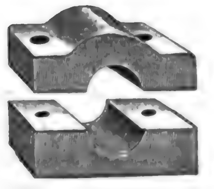

FIG. 1.

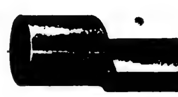

FIG. 2.

section to come within the limits set by Table XVI, and they should be long enough to permit any transposition that might be found advisable after the machine is put into service.

TABLE XVI.—MAXIMUM ALLOWABLE CURRENT IN MAIN LEADS FROM BRUSHES.

Equivalent size; B. & S. gauge.	Amperes.	Equivalent size; B. & S. gauge.	Amperes.
14	9	3	60
12	12	2	70
10	18	1	80
8	25	0	95
6	33	00	110
5	42	000	135
4	50	0000	160

The terminal blocks should be made of slate or marble, mounted on kiln-dried wood to reduce the shocks due to moving the machine around; the wood base should be made up in at least two, and preferably three, layers, the grain being crossed in the adjacent layers. The terminals may be in the form of ordinary binding posts for currents of 25 amperes or less, but in all cases the binding screw should be large in diameter and provided with a large milled head for setting it up by hand; an ordinary screw requiring the use of a screwdriver should never be used. For currents above 25 amperes, the terminals should be either of the clamp type indicated in Fig. 1, the leads being equipped with soldered lugs to fit the opening between the clamp members, or else simple metal blocks, carefully faced off and of the proper size to accommodate the flat part of a lug like that shown in Fig. 2. This lug is, of course, soldered to the end of the lead.

The instructions given in the preceding articles are sufficiently general to cover any voltage for which the amateur may wish to build his machine, excepting the data contained in Tables I and XI relating to armature current per wire and to the size of wire to be used in the field-magnet winding, respectively. In order to ascertain the armature current per wire for machines of other voltages than the standards specified in the table, it is only necessary to divide the armature watts by the voltage and then divide the result by the number of paths

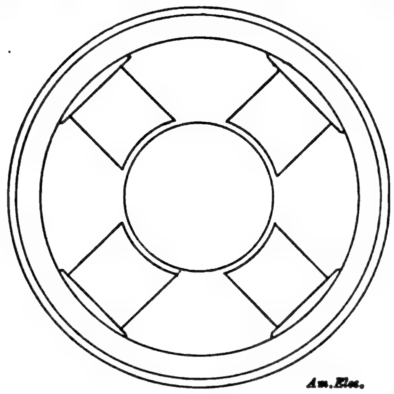

FIG. 3.

in the armature winding. Having the current per wire, Tables III, IV and VI may be applied to any machine, no matter what its e.m.f.

In order to apply Table XI to a machine of special voltage, one needs only to ascertain the size of wire that would have to be used for the nearest standard voltage and then make correction by means of Table XVII, as follows:

In the proper line at the top of the proper section of the table, find the size of wire required for the nearest standard voltage; in the same column in the body of the table find the nearest voltage to that of the machine, then trace horizontally along the line in which this voltage is found until the extreme right-hand column is reached. The number in that column will be the proper size of wire to use. Example: Suppose that the actual voltage of the machine is to be 60 volts, and the excitation test, made with No. 16 wire, showed 86 volts necessary to excite the field; Table XI, first section, would show that for 110 volts, the field winding would need to be of No. 17 wire. Now, referring this to Table XVII, first section, No. 17 is located in the upper (110-volt) headline of the table in the fifth column, and tracing down this column into the body of the table, the number 55 is found to be the nearest to the voltage of the machine. Tracing to the right along this line,

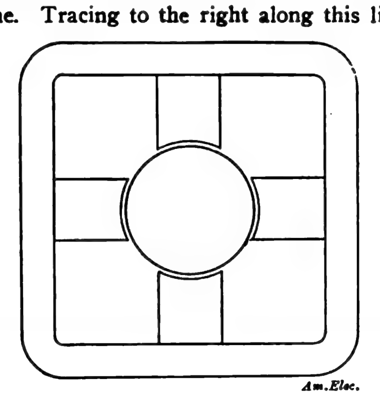

FIG. 4.

in the right-hand column is found the number 14, and this is the size of wire to be used. If the machine voltage had been 7 instead of 60, the nearest number in the fifth column would have been 6.8, and the size of wire in line with this is 5, which would have been the proper size to use for 7 volts.

In connecting the armature winding of a machine to the commutator lugs it is advisable to keep in mind the disposition of the field magnet poles about the axis and to carry the armature leads to the commutator in such a way as to cause the most favorable location of the brushes about the commutator. In the case of a four-pole machine, it is always advisable to have the brushes make contact on the commutator 90 degrees each side of the vertical diameter, no matter whether there be two or four brush positions. If the field magnet poles are distributed as in Fig. 3, then in order to get the brush contacts 90° from the vertical diameter the two leads from each coil must be bent sidewise equal distances from the center of the coil, as indicated diagrammatically in Fig. 5, for a wave-connected winding. For a lap winding, the

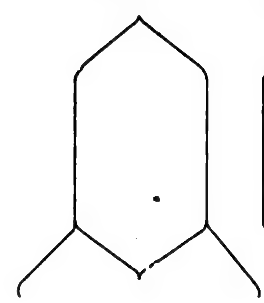

FIG. 5.

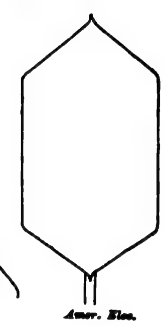

FIG. 6.

leads must go to the commutator as nearly opposite the center of the coil as possible, as indicated diagrammatically in Fig. 6.

When the magnet poles are arranged as in Fig. 4, one lead of each armature coil must go to the commutator segment opposite the "side" of the coil from which the lead is taken, as indicated in Figs. 7 and 8 for wave-connected and lap windings, respectively. Consideration of Fig. 8 will show that the arrangement of the lead, *a*, is awkward in the extreme, and as a matter of fact it would be almost impracticable to carry out the lead in this fashion in actual work; a much better disposition of it is to carry it past the central bend of the coil and over to the point where the other lead comes out from the taping, as indicated by the dotted lines. Most armature winders bring

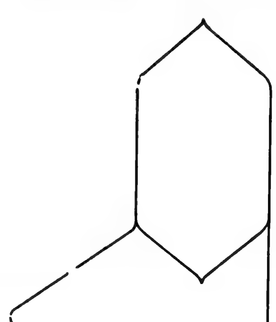

FIG. 7.

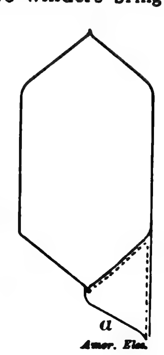

FIG. 8.

both leads out from the center of the coil, as in Fig. 6, and bend both of them to the right or left a distance equal to one-half of the magnet pole pitch, but the arrangement of Fig. 8, substituting the dotted line arrangement of the lead *a*, is much prefer-

able, for the reason that the leads then go straight out to the commutator and do not require to be "bedded" closely together, as on the horizontal diameter of the yoke ring, the other four being arranged, of course, in pairs with the two poles of each pair equal of the winding. Then, with a wave-connected winding and two groups of brushes, the brushes should touch the commutator at

they do when carried diagonally to the commutator.

The field magnet of a small six-pole machine should always be built with two poles distances from the vertical diameter of the machine. The leads from the armature to the commutator should be carried out as in Fig. 5 or Fig. 6, according to the character the ends of the horizontal diametrical line; with six groups of brushes, each group will set practically opposite the center of a field magnet pole.

POWER HOUSE NOTES.

BY ARTHUR B. WEEKS.

In a certain power house, it was found necessary to increase the field strength of a rotary converter. The original field winding was as shown on the machine on the right of Fig. 1. As there was not sufficient space for making a larger field-magnet coil wound in like manner, each new field coil was divided into two parts, with ventilating

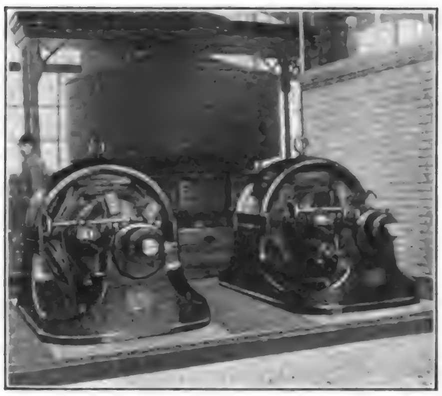

FIG. 1.—ROTARY CONVERTERS.

spaces between, as shown in the rotary at the left of the illustration. Fig. 2 gives a clearer idea of the arrangement. To drill the holes in the field-magnet core for securing the new coils, a ratchet drill and "old man" were utilized. At one time the field-magnet coils of one of these machines were badly scorched, because the operator in opening the switches neglected to pull out the alternating-current plug switches. When the current was thrown on the bus-bars again, the field winding was burned out, and it was replaced with the divided form of coil.

Before installing the new coils, they were laid out on the floor and tested for polarity, as shown in Fig. 3; the two coils per pole are represented by the large and small squares. Current was supplied by the other rotary for testing. The coils alternate in polarity, of course, this being made sure by testing with a dipping magnetic needle which is free to turn completely over.

Rotary converters can be used as ex-

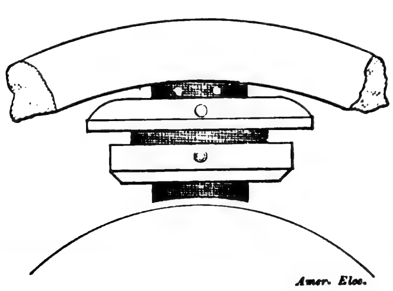

FIG. 2.—FIELD COILS OF ALTERED ROTARY.

citers with gratifying results, and with but one drawback; when there is a short-circuit on the lines, the machines stop, of course, their source of current being cut off, and direct current must be available in order to start up the plant without waiting for the alternating-current trouble to be cleared. Another, but less important disadvantage is that if the direct-current bus-bar switches are opened and one forgets to open the alternating-current switches, when the current is thrown on the bus-bars again the

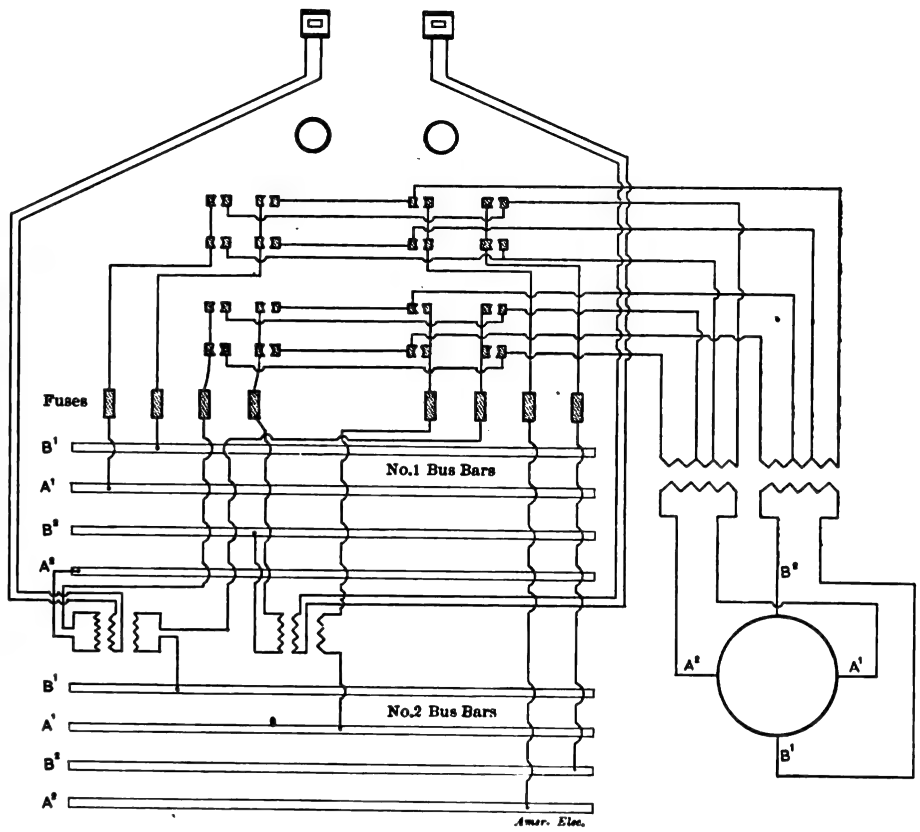

FIG. 5.—DIAGRAM OF CONNECTIONS.

armature cannot revolve, and if the neglect is not discovered in time the field-magnet coils will burn out. This trouble, however, should not occur in any well-attended station.

Fig. 4 shows a panel for one of the rotaries already mentioned. There are a direct-current voltmeter, a direct-current ammeter, and two alternating-current ammeters, one for each set of bus-bars. Plug switches are used. As shown, the switches are on bus-bars No. 2. At the small panel in front are the field rheostat wheel, a lever controlling the direct-current circuit-breaker, an alternating-current changing switch, and levers for direct-current bus-bar switches Nos. 1 and 2. The rotary, which is a two-phase machine, can be run from either the No. 1 or the No. 2 alternating-

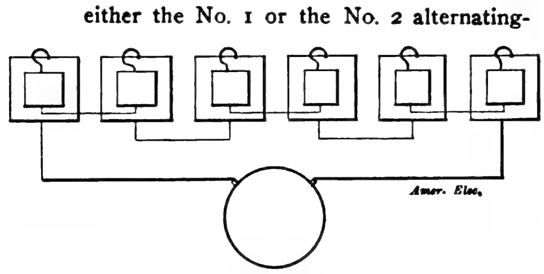

FIG. 3.—TESTING POLARITY OF COILS.

current bus-bars, or both, and supply direct current to either or both of the direct-current bus-bars, as will be evident from Fig. 5. The machine can be operated from both sets of the alternating-current bus-bars simultaneously only when these are in parallel, of course; failure to remember this would cause trouble if the other alternating-current plug switches were pushed in during the running of the machine.

Direct-current exciters can be run in parallel on direct-current bus-bars with rotary converters, but the voltage and speed of the direct-current machines must, of course, be properly regulated to enable them to take their proper part of the load.

The usual method of starting large rotary converters is to plug them in on the line at the alternating-current side while at a standstill. This causes a very bad surge

FIG. 4.—SWITCHBOARD PANEL FOR ROTARY.

in the line voltage, and as often as the converter does not build up right the operation must be repeated. This and other bad features of starting may be avoided by connecting up an alternator on these bars, separately excited by itself and running at slow speed and with a very weak field; then closing the feeder switch and trying the

rotary. If the polarity is right, the generator speed and field strength are increased until the running voltage is attained. If desired, this alternator may then be paralleled with the others on the other bus-bars. After one rotary has been started, as just described, others may be started as usual on the direct-current side.

To start a rotary converter with connections as in Fig. 5, all the switches at the upright panel and the small panel at the front must be open; then the changing switch on the small panel at the alternating-current side is closed and plugs inserted in the two lower plug sockets on the main board. These represent one leg of each phase. Next, two plugs are put in the two upper receptacles. If the machine builds up right, the changing switch is thrown from the alternating-current to the direct-current side, and the two top switch plugs are changed one at a time to the next lower receptacles. In the first position, choke coils were in circuit; the next operation cuts them out. The phases are arranged vertically on the board, not across it. The field strength is then increased until normal voltage is attained. If the field is too strong the ammeter will indicate excessive alternating current. Should the machine not build up right in starting, the last two plug switches are withdrawn and another attempt made after a wait of a few moments.

LOCATION AND CARE OF STEAM GAUGES.

BY W. H. WAKEMAN.

As principles which cause steam gauges to give correct results are not always understood by men who have charge of them, the following illustrations and explanations

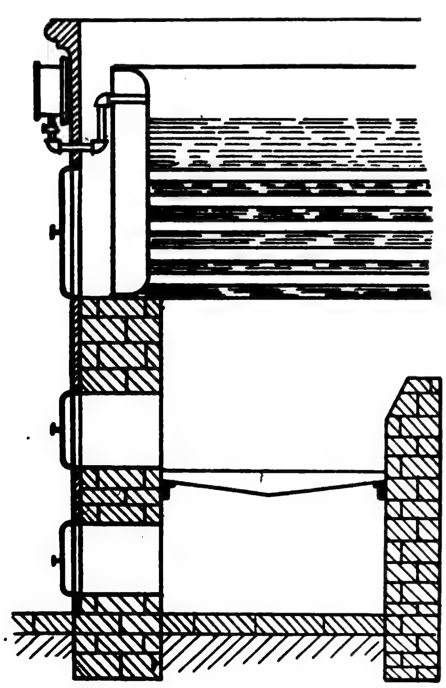

FIG. 1.

taken from everyday practice will doubtless be of interest.

Fig. 1 shows a method of connecting gauges adopted by a firm that turns out hundreds of good tubular boilers. A one-quarter inch pipe is connected into the front head above the water line. A loop is formed

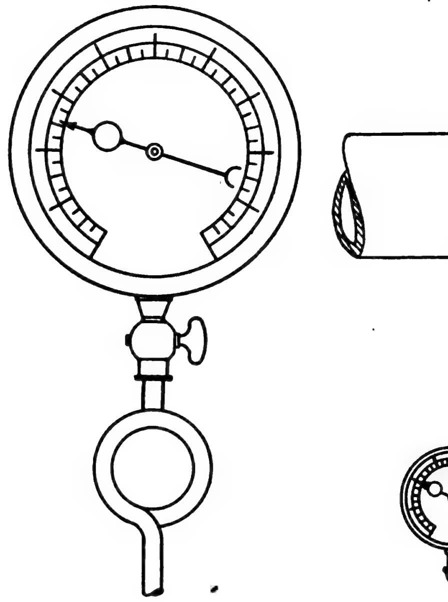

FIG. 2.

by nipples and ells, which causes water to stand in this pipe, thus protecting the gauge from the heat of the steam.

This method of connection works fairly

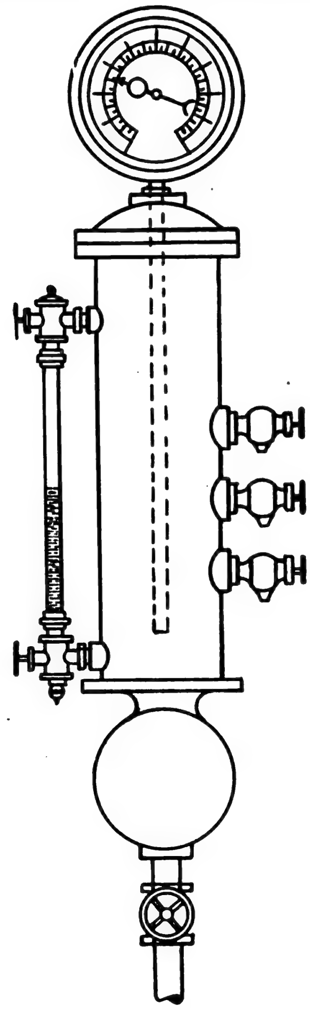

FIG. 3.

well when the boiler is under a light load, but when the boiler is worked to its full capacity this little pipe is in the midst of hot gases on their way to the chimney, which heat it, and probably evaporate the water in the loop.

To avoid this possible danger these pipes may be taken out of the boiler and located in plain sight. Each loop is connected into another pipe without a valve between this connection and the steam space of boiler, although a valve may be placed in the small

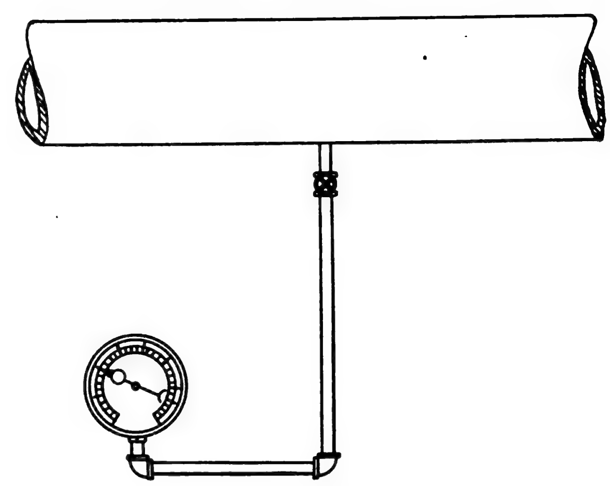

FIG. 4.

pipe near the connection. It is customary to locate a double ended pet cock under the gauge in such a case, but it is omitted here, therefore leaks from this source do not annoy the fireman by dropping water on the furnace doors.

A union is located at this point so that when the pipe needs cleaning the one-quarter-inch valve is closed, the union disconnected and the valve opened under a full head of steam, thus blowing out all sediment. After this the pipe is allowed to cool; then the union is connected and steam turned on. Enough steam is condensed to protect the gauge. Where a pet cock is provided in a connecting pipe it is customary in some plants to draw the water out of this pipe frequently without shutting off the gauge, but this is wrong, because heat thus admitted to the spring injures it. Brass pipe should be used for such service as it does not corrode as quickly as iron pipe.

The siphon shown in Fig. 2 keeps water in the pipe at all times, but it has a disadvantage in that there is no provision made for cleaning it without disconnecting the gauge. Water cannot be drained out, so that if the gauge is located in an exposed position the water is liable to freeze in cold weather, thus preventing the gauge from indicating correct pressure. Accidents have happened from this cause in the past, and probably will in the future.

Fig. 3 shows another plan for protecting a gauge. Under normal conditions this gives good results; but when the lower drip valve is opened to blow sediment out of the column, the end of the connecting pipe, shown in dotted lines, is above the water line, so that steam is admitted to the gauge, endangering the spring.

The supposition that a good gauge will always correctly indicate the boiler pressure, regardless of the way in which it is connected, is erroneous, as the following illustrations will show.

Fig. 4 represents a low-pressure gauge attached to a steam heating main. A column

of water always stands in this pipe, and the vertical distance from the center of the gauge to the top of this water is 8 feet 4 inches. The actual pressure at this point, without steam in the main pipe, is 3.6 pounds, due to the weight of the water. The dial of this gauge is graduated into pounds, so that the indicators should stand at about three-quarters of the distance between 3 and 4 pounds, when no steam is in the mains. When reading the pressure on this heating main, this amount should be subtracted from the pressure the gauge indicates.

Fig. 5 illustrates a gauge located on the floor above the boiler room. If a gauge so placed is piped so that all water drains back into the boiler, it will indicate correctly; but

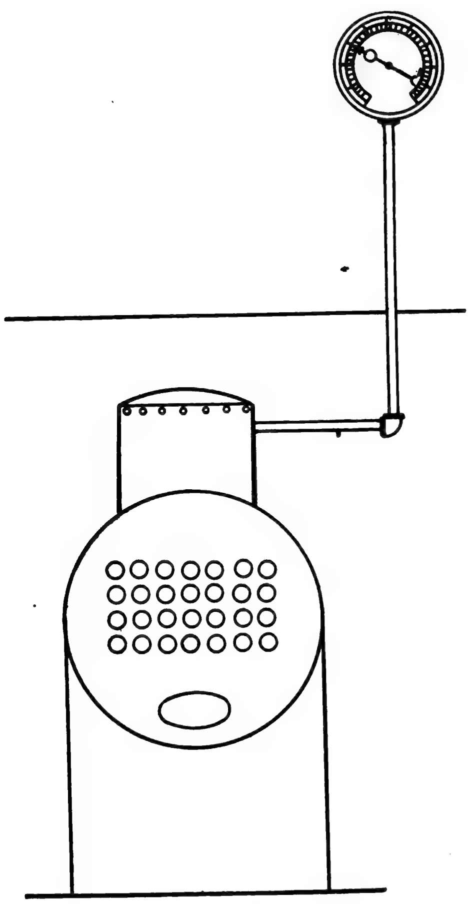

FIG. 5.

if the connecting pipe contains water, the gauge will indicate one pound less than correct steam pressure for each 27.7 inches vertical height of water. In other words, the result will be directly opposite to that obtained with the arrangement shown in Fig. 4, although both gauges may be correct.

Fig. 6 shows a steam gauge attached to a Manning boiler. It is connected into the shell just above the crown sheet, consequently the weight of water above the gauge creates a pressure which must be subtracted from the indicated pressure to obtain the true head of steam carried.

In a plant where this kind of boiler is in use, the inspector objected to the pressure carried, as it was more than 5 pounds above the limit fixed. The engineer claimed that he was allowed to carry a certain steam pressure, and that the water as above described, was responsible for the surplus pressure indicated. Now, the safe working pressure of a boiler as fixed by an insurance company, is based on the estimated strength of the shell, heads and tubes; consequently the limit should not be exceeded, regardless of what causes said pressure. If a gauge located as shown in Fig. 6 shows

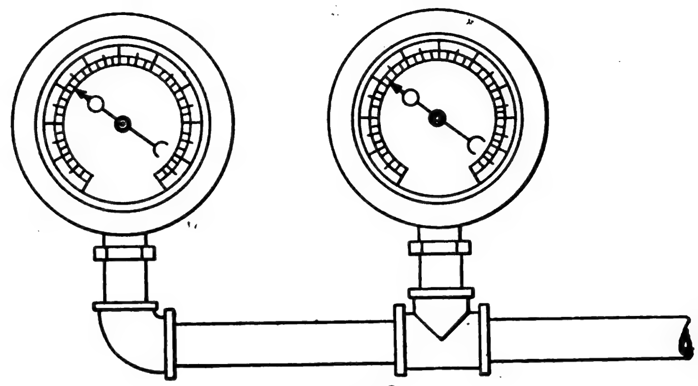

FIG. 8.

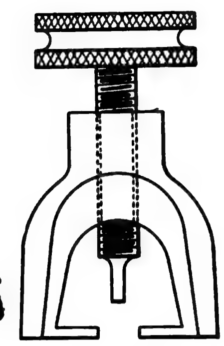

FIG. 9.

100 pounds, 10 of which are due to weight of water, it is the same as if 100 pounds of steam was carried on a horizontal boiler, or one of the water-tube type where the height of water is not enough to make much difference, therefore the gauge should never show more than the amount allowed.

Of course this ruling gives less available pressure for a vertical than for a horizontal boiler, and the difference is enough in many cases to seriously affect the engines using steam, but it keeps one on the safe side, which is a very important point.

Although a steam gauge may be correct when new, it does not necessarily follow

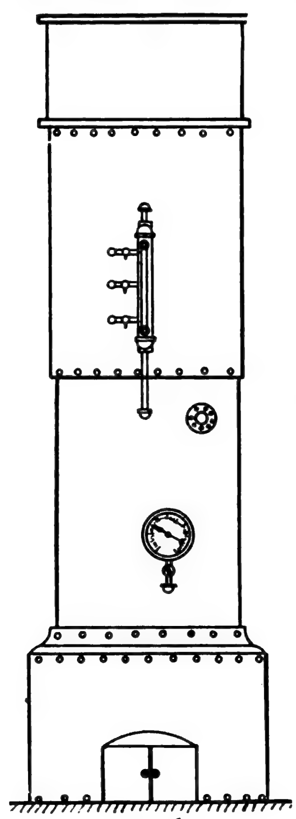

FIG. 6.

that it will remain so, therefore every gauge should be tested at least once a year. This does not mean that in a plant where a score or more are in use, each one should be disconnected and tested separately, as that plan would make much unnecessary work. If a certain gauge is tested each year, and all others indicate similar pressure, where they are connected in the same way, no further proof of their accuracy is needed. Where they are connected in different ways and indicate different pressures, if they maintain the same difference towards the one tested, it shows that no change has taken place in them, and this is sufficient proof of their condition.

Fig. 7 illustrates an instrument for testing gauges. The body is partly filled with oil and a small plunger inserted. This carries with it a circular platform upon which the desired number of weights are placed. Five are shown in the illustration, the three bottom ones indicate 20 pounds each, the next indicates 10 and the top one 5 pounds pressure to the square inch, consequently when the adjusting handle is screwed inward, so as to just float the tightly fitting plunger in the oil, the pointer will indicate 75 pounds if all parts are properly adjusted.

As such an instrument is expensive, it is not always available for testing purposes. A good substitute, which can be made by any engineer, is illustrated in Fig. 8. A gauge known to be correct is connected into a tee as shown and one to be tested connected in parallel with it. The full working pressure of steam is then turned on and the indications of the pointers compared. If the indicators do not agree the

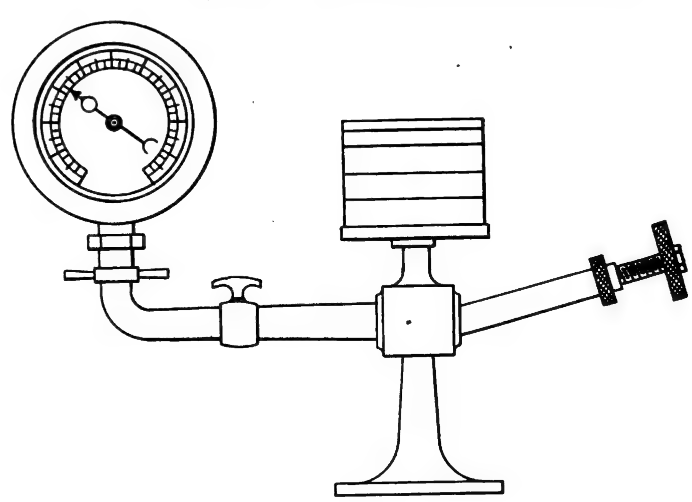

FIG. 7.

one from the defective gauge is removed and replaced so as to agree with the other. A little instrument that is very convenient for this purpose is shown in Fig. 9 and its application is illustrated in Fig. 10. Screwing down the gnarled handle draws

the pointer upward, unseating it from the central pivot, after which it is forced on again, care being taken to place it so as to agree with the other gauge.

The advisability of adjusting a gauge ac-

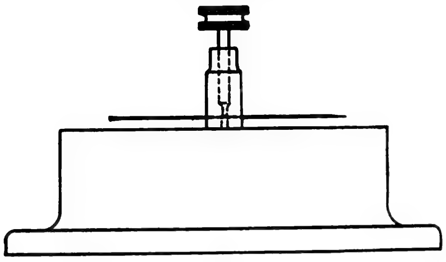

FIG. 10.

cording to this method has been disputed, but it certainly indicates the correct working pressure, if directions are followed, and that is the object sought.

DISEASES OF ELECTRICAL MACHINERY.

BY F. B. CROCKER AND S. S. WHEELER.

D. Heating of Field-Magnets.

All direct-current generators and motors as well as alternating-current generators, synchronous motors and rotary converters, have field magnets excited by direct current. Induction motors and generators, also single-phase, self-starting motors, carry alternating current in their field coils, but the following troubles might occur in any of these types:

Cause 1.—Excessive current in field circuit.

Symptom.—Field coils too hot to be bearable to the hand. Their temperature more than 50 degs. C. above that of the room by resistance test or 50 degs. C. by thermometer. (See methods already given.)

Remedy.—In the case of a shunt-wound or separately excited machine decrease the voltage at terminals of field coils, or increase the resistance in field circuit by winding on more wire or by putting resistance in series. In the case of a series-wound machine, shunt a portion of, or otherwise decrease, the current passing through the field, or take a layer or more of wire off the field coils, or rewind with coarser wire. This trouble might be due to a short-circuit in field coils in the case of a shunt-wound or separately excited generator or motor, and would be indicated by one pole-piece with the short-circuited coil being weaker than the others; a wholly or partially short-circuited field coil being also *cooler* than the others. The short-circuiting of a portion of the field circuit may not cause serious harm. In this respect it differs radically from a short circuit of even one turn of wire in the armature. (See "Sparking," Cause 5.) Measure resistance of field coils to see if they are nearly equal. If the difference is considerable (*i.e.*, more than 5 per cent.), it is an almost sure sign that one coil is short-circuited or double-grounded. (See "Sparking," Causes 8 and 9.)

Cause 2.—Eddy or Foucault currents in pole pieces.

Symptom.—The pole pieces hotter than the coils after a short run.

Remedy.—This trouble is either due to faulty design and construction, which can only be corrected by rebuilding, or else it is caused by fluctuations in the current. The latter can be detected if the variations are not too rapid, by putting an ammeter in circuit, or rapid variations may be felt by holding a piece of iron near the pole pieces and noting whether it vibrates. In the case of an alternating current it is necessary to use laminated fields to avoid great heating, and the ordinary arc currents fluctuate enough to cause some trouble in this way. In fact, the currents generated by the open-coil armatures used in arc lighting (Thomson-Houston and Brush) are decidedly pulsating in character. With this exception, however, direct currents rarely pulsate sufficiently to cause heating due to eddy currents.

Cause 3.—Moisture in field coils.

Symptom.—Field-circuit tests lower in resistance than normal in that type of machine, and in the case of shunt-wound machines the field takes more than the ordinary current. Field coils steam when hot, or feel moist to hand. The insulation resistance also tests low.

Remedy.—The same as for moisture in armature. (Heating of Armature, Cause 3.)

E. Heating of Bearings.

This may arise in almost any machine, including all direct-current as well as alternating-current generators and motors. The cause should be found and removed promptly, but heating of the bearings may be reduced temporarily by applying cold water or ice to them. This is only allowable when it is absolutely necessary to keep running, and great care should be taken not to allow any water to get upon the commutator, armature, or field coils, as it might short circuit or ground them. If the bearing is very hot, the shaft should be kept revolving slowly, as it might "freeze" or stick fast if stopped entirely.

Cause 1.—Lack of oil.

Symptom.—Oil cup or reservoir empty. Oil passages clogged. Self-oiling rings, or other devices not revolving or acting properly. Shaft and bearing look dry. The shaft does not turn freely.

Remedy.—Supply oil, and make sure that oil passages as well as feeding or self-oiling devices work freely, and that the oil cannot leak out. This last fault sometimes causes oil to fail sooner than attendant expects. Good quality of oil should always be used, as poor oil might be as bad as no oil.

Cause 2.—Grit or other foreign matter in bearings.

Symptom.—Best detected by removing shaft or bearing and examining both. Any grit can, of course, be felt easily, and will also scratch the shaft.

Remedy.—Remove shaft or bearing, clean both very carefully, and see that no grit can get in. Place machine in a dustless place or box it in. The oil should be perfectly clean; if not, it should be filtered. If it is not possible to stop the machine or to remove the shaft the dirt might be washed out with kerosene or water, but these should not be allowed to get on the commutator, armature, or field coils, and should be removed as completely as possible afterward, lubricating oil being again introduced.

Cause 3.—Shaft rough or cut.

Symptom.—Shaft will show grooves or roughness, and will probably not revolve freely.

Remedy.—Turn shaft in lathe or smooth with fine file, and see that bearing is smooth and fits shaft.

Cause 4.—Shaft and journal fit too tight.

Symptom.—Shaft does not turn easily, but excessive friction is immediately and completely relieved by slight loosening in the case of a split journal. In case the latter is not split, the bearing cap may be removed, and the journal examined to see whether it grips the shaft tightly.

Remedy.—Turn or file down shaft in lathe, or scrape or ream out journals.

Cause 5.—Shaft "sprung" or bent.

Symptom.—Shaft hard to revolve, and usually sticks much more in one part of its revolution than in another.

Remedy.—It is very difficult to straighten a bent shaft. It might be bent back or turned true, but probably a new shaft will be necessary.

Cause 6.—Bearings out of line.

Symptom.—Shaft does not revolve freely, but is much relieved by slightly loosening the screws which hold bearings in place.

Remedy.—Loosen the bearings by partly unscrewing bolts or screws holding them in place, and find their easy and true position, which may require one of them to be moved either sideways or up and down; then file the screw-holes of that bearing or raise or lower it, as may be necessary, to make it occupy the right position when the screws are tightened. The revolving part must be kept, however, in the center of the space in which it turns, so that the clearance is uniform all around. (See Cause 9.)

Cause 7.—Thrust or pressure of pulley, collar, or shoulder on shaft against one or both of the bearings.

Symptom.—In the case of a belt-connected machine, move the shaft back and forth with a stick applied to the end while revolving, and note whether the collar or shoulder tends to be pushed or drawn against either bearing. It is usually desirable that a shaft should move freely back and forth an eighth of an inch to make the commutator and bearings wear smooth. (See "Sparking," Cause 3.)

Remedy.—Line up the belt, shift the collar or pulley, turn off the shoulder on shaft or file off the bearing until the shoulder does not touch when running or until pressure is relieved.

Cause 8.—Too great load or strain on the belt.

Symptom.—Great tension on belt. The pulley bearing is probably much hotter than the other, and in time will be worn elliptical, in which case the shaft may be shaken in the bearing in the direction of the belt pull, when the belt is off.

Remedy.—Reduce the load or belt tension, or use larger pulleys and lighter belt, so as to relieve side strain on shaft.

Cause 9.—Armature nearer the pole pieces on one side, producing greater magnetic attraction on nearer side.

Symptom.—Examine the clearance to see if it is uniform on all sides. Charge and discharge the field magnet, the armature being disconnected (by lifting the brushes or otherwise), and note whether armature seems to be drawn to one side and turns very much less easily when field is magnetized.

Remedy.—See "Sparking," Cause 9, and remedy therefor. This condition does not produce sparking or armature heating except in multipolar direct-current machines with multiple-circuit armature windings. It can produce heating of bearings in any machine, but is worse with multipolar than with bipolar machines; therefore, the clearance between the armature and pole pieces should be larger in the former than in the latter. This difficulty always tends to become aggravated, because the more the side pull, the more the bearings wear in that direction. If, on the other hand, the armature is in the center of the space formed by the pole pieces, the magnetic pull is practically balanced in all directions.

Cause 10.—Bearing heated by hot pulley, commutator, or armature.

Symptom.—Pulley, armature, or commutator hotter than bearing. The slipping of the belt on the pulley, sparking at the commutator, or heating of the armature may heat one or both bearings of the machine, in which case an examination will show that these parts are hotter than the bearing and are the real source of the trouble.

Remedy.—A slipping belt, sparking commutator, or hot armature can be cured as described under these headings, and then the bearing will probably cease to heat.

F. Noisy Operation.

This trouble may occur in any electrical machine, except that Cause 5 (noise due to brushes) is not likely to be serious in alternating-current machines having no commutator. Nevertheless, the brushes on the collector rings may make a noise, for example, when the latter are rough.

Cause 1.—Vibration due to armature, revolving field, pulley or other moving part being out of balance.

Symptom.—Strong vibration felt when the hand or a stick of wood is placed upon the machine while it is running. Vibration changes greatly if the speed is changed, and sometimes almost disappears at certain speeds.

Remedy.—Armature, pulley or other revolving part must be perfectly balanced by *securely* attaching lead or other weight on the light side, or by drilling or filing away some of the metal on the heavy side. The easiest method of finding in which direction it is out of balance is to take it out and rest the shaft on two parallel and horizontal A-shaped metallic tracks sufficiently far apart to allow the armature to go between them. If the armature is then slowly rolled back and forth, the heavy side will tend to turn downward. The armature and pulley should always be balanced separately. An excess of weight on one side of the pulley and an equal excess of weight on the opposite side of the armature will not produce a balance while running, though it does when standing still; on the contrary, it will give the shaft a strong tendency to "wobble." A perfect balance is only obtained when the weights are directly opposite, *i.e.*, in the same line perpendicular to the shaft.

Cause 2.—Armature strikes or rubs against pole pieces.

Symptom.—Easily detected by placing the ear near the pole pieces or by examining armature to see if its surface is abraded at any point, or by examining each part of the space between armature and field, as armature is slowly revolved, to see if any portion of it touches or is so close as to be likely to touch when the machine is running. In small machines the armature may be turned slowly by hand or with a lever to ascertain whether it tends to touch or "stick" at any point.

Remedy.—Bind down any wire or other part of the armature that may project abnormally; chip or file out the pole pieces where the armature strikes; or center the armature so that there is a uniform clearance between it and the pole pieces at all points.

Cause 3.—Shaft collar or shoulder, hub or edge of pulley, or belt strikes or scrapes against bearings.

Symptom.—Rattling noise, which stops when the shaft, pulley or belt is pushed lengthwise away from one or the other of the bearings. (See "Heating of the Bearings," Cause 7.)

Remedy.—Shift the collar or pulley, turn off the shoulder on the shaft, file or turn off the bearing, move the pulley on the shaft or straighten the belt until there is no more striking and noise ceases.

Cause 4.—Rattling due to looseness of screws or other parts.

Symptom.—Close examination of the bearings, shaft, pulley, screws, nuts, binding posts, etc., or touching the machine while running or shaking its parts while standing still, shows that some part is loose.

Remedy.—Tighten up the loose parts, and be careful to keep all properly set up. It is an easy matter to guard against the occurrence of this trouble, which is very common, by simply examining the various screws and other parts each day before the machine is started. Electrical machinery being usually high speed, the parts are particularly liable to shake loose. A worn or poorly fitted bearing might allow the shaft to rattle and make a noise, in which case the bearing should be refitted or renewed.

Cause 5.—Humming, squeaking or hissing of brushes.—This is often occasioned by rough or sticky commutator (see "Sparking," Causes 3 and 4). The commutator and brushes of a new machine may make considerable noise that is reduced after it has been running for a day or two.

Symptom.—Sound of high pitch, and easily located by placing the ear near the commutator while it is running, and by lifting off the brushes one at a time, provided that the circuit is not opened thereby.

Remedy.—Apply a *very little* oil or vaseline to the commutator with the finger or a rag. Adjust the brushes or smooth the commutator by turning, filing, or fine sandpaper, being careful to clean thoroughly afterwards. Carbon brushes are apt to squeak in starting up or at low speed. This decreases at full speed, and can usually be reduced by slightly moistening the brush with oil, care being taken not to have any drops or excess of oil. Shortening or lengthening the brushes sometimes stops the noise. Run the machine with little or no load until the commutator and brushes are worn smooth.

Cause 6.—Flapping or pounding of belt joint or lacing against pulley.

Symptom.—Sound repeated once for each complete revolution of the belt, which is much less frequent than any other generator or motor sound, and can easily be detected or counted.

Remedy.—Endless belt or smoother joint.

Cause 7.—Slipping of belt on pulley due to overload.

Symptom.—Intermittent squeaking noise.

Remedy.—Tighten the belt or reduce the load. A wider belt or larger pulley may be required. Powdered rosin may be put on the belt to increase its adhesion; but it is a makeshift, injurious to the belt, only to be adopted in an emergency. Special belt dressings are sold, which increase the adhesion and at the same time are intended to preserve the belt.

Cause 8.—Humming of armature core teeth as they pass pole pieces.

Symptom.—Pure humming sound less metallic than that due to Cause 5.

Remedy.—Slope or chamfer the ends of the pole pieces so that each armature tooth does not pass the edge of the pole piece all at once. Decrease the magnetization of the fields. Increase the cross-section or magnetic capacity of the teeth, or reduce that of the body of the armature. But these are nearly all matters of first construction, and are made right by good manufacturers.

Cause 9.—Humming due to alternating or pulsating current.

Symptom.—This gives a sound similar to that in the preceding case. It can be distinguished, by determining whether the note given out corresponds to the number of alternations, or to the number of armature teeth passing per second. Usually the latter is considerably greater than the former. This trouble is naturally confined to alternating-current apparatus. The slight pulsations occurring on direct-current circuits due to the commutator are hardly sufficient to produce an audible sound except in a telephone. (See "Heating of Field Magnets," Cause 2.)

Remedy.—It is practically inherent in alternating apparatus, but its effects can be reduced by mounting the machine so as to deaden the sound as much as possible.

Note.—It often happens that a generator or motor seems to make a noise that in reality is caused by the engine or other machine with which it is connected. Careful listening with the ear close to the different parts will show exactly where the noise originates. A very sensitive way to locate a noise or vibration is to hold a short stick or pencil by one end between the teeth and press the other end squarely against the several parts, to ascertain which particular one gives the greatest vibration.

Principles of Electrical Apparatus

THE SYNCHRONOUS MOTOR.—PHASE RELATIONS.

If there were no armature reaction and the armature circuit were not self-inductive, the current taken by a synchronous motor would always be in phase with its e.m.f. and the counter e.m.f. generated by

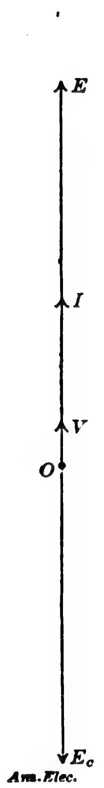

FIG. 1.

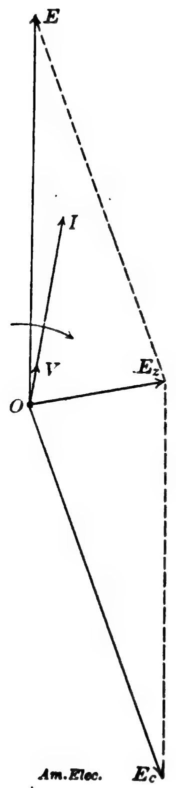

FIG. 3.

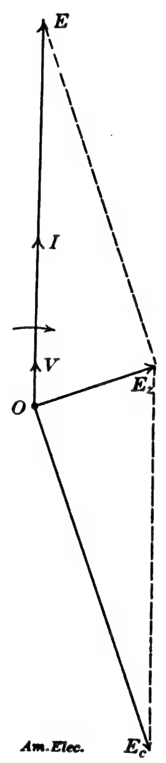

FIG. 4.

the armature would be squarely opposed to the impressed e.m.f. Such an ideal state is represented vectorially by Fig. 1, where *O-E* represents the phase and relative value of the impressed e.m.f.; *O-V*, the phase and value of the e.m.f. expended

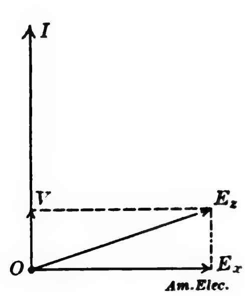

FIG. 2.

in the winding in forcing current through its resistance, and *O-E_c* the phase and value of the counter e.m.f. of the armature. Under such a condition the counter e.m.f. is evidently equal to the impressed e.m.f. minus the resistance drop in volts.

However, the armature of a synchronous motor exerts a most vigorous reaction upon the magnetic flux of the field magnet. And, like any other magnetic body encircled by conductors which are traversed by alternating current, it is highly self-inductive; consequently, if an alternating current be passed through the winding it will lag behind its e.m.f. by reason of the reactance of the armature, whether the armature be rotating or at rest. The component of the impressed e.m.f. which is consumed by the resistance of the winding will be in phase with the current, of course, as indicated by the arrow-head, *V*, Fig. 2. The self-induced or reactance e.m.f. lags 90° behind the current, so that the component of the impressed e.m.f. which counterbalances this reactance e.m.f. must lie 90° *ahead* of the current as indicated by the vector, *O-E_x*. The resultant of the e.m.f's expended in overcoming resistance and neutralizing reactance is obtained by the usual parallelogram method; the vector, *O-E* , represents this.

Now the only other e.m.f. that opposes the impressed e.m.f. is the counter e.m.f. generated by the rotation of the armature in the magnetic field exactly as in the case of a generator The value of this counter e.m.f. depends entirely upon the strength of the field excitation, as in a direct-current machine; but, unlike a direct-current motor, the field excitation and, consequently, the counter e.m.f., do not affect the speed of the machine, because, as explained last month, the speed must have an absolutely fixed ratio to the frequency of the supply current, and cannot vary unless that frequency varies. The result is that altering the field excitation of a synchronous motor not only alters the value of its counter e.m.f. but shifts the phase of that e.m.f., as will be evident presently.

The vector sum of the counter e.m.f. and the impedance e.m.f. ($E^\bullet$) equals the impressed e.m.f. These two e.m.f's are combined by the parallelogram method, exactly as in the previous case. Fig. 3 is a diagram showing the combination of the impedance e.m.f., E_c, with the counter e.m.f., E_c, to give a resultant equal to the impressed e.m.f., *E*. The curved arrow which crosses the impressed e.m.f. and armature current vectors indicates the direction in which the figure is supposed to be revolving. In the case here shown the field excitation of the machine has been adjusted so that the counter e.m.f., E_z is precisely equal to the impressed e.m.f., *E*. The diagram shows that in this case the armature current represented by the vector, *O-I*, leads the impressed e.m.f. to a slight extent. Assuming a constant load on the motor, only a slight reduction in the field excitation would be required to reduce the counter e.m.f. sufficiently to allow the current to come precisely in phase with its e.m.f., as indicated in Fig. 4, where all of the constants forming the basis of Fig. 3 have been retained with the exception of the counter e.m.f.

It will be noticed upon very close inspection that the vectors, *O-I*, representing the armature current; *O-V*, representing the resistance drop, and *O-E_z* representing the impedance drop, are all a trifle shorter than in Fig. 3. The explanation of this is that with a constant load the amount of current required is less when that current is in phase with its e.m.f., as represented in Fig. 4, than when there is a difference in phase, as in Fig. 3. The power factor of the motor is equivalent to the cosine of the angle between the two vectors, *O-E* and *O-I*.

If, now, the field excitation be still further reduced, the counter e.m.f. will also be reduced and the current will lag behind the e.m.f., the extent of this lagging being determined by the extent to which the field excitation is reduced. Fig. 5 shows the condition when the field is weakened sufficiently to allow the current to lag 30°, or 1/12 of a cycle. In this case the impressed e.m.f. and load remaining unchanged, the armature current is increased

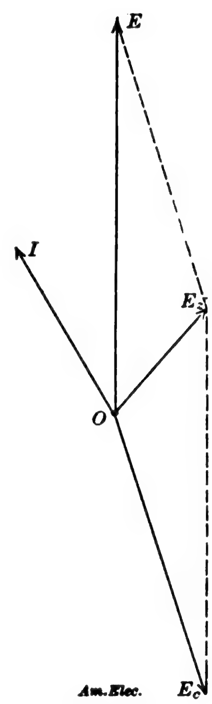

FIG. 5.

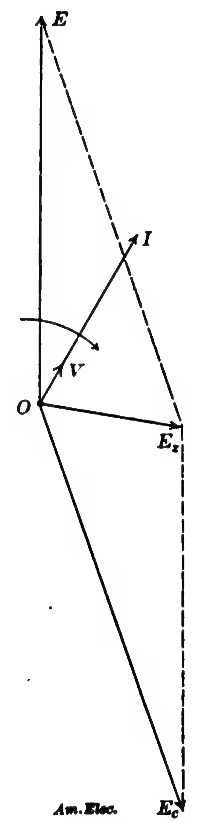

FIG. 6.

considerably, and consequently the resistance drop and impedance drop are also increased, as these vary directly with the armature current.

Fig. 6 represents the phase relations with the counter e.m.f. increased (by strengthening the field excitation) until the current *leads* the e.m.f. 30°; the current strength is precisely the same as when there was a lag of 30° as shown in Fig. 5. It is evident, therefore, that with the load constant, if a certain field excitation allows a lagging current of a certain value to flow, a leading current of precisely the same value can be obtained by strengthening the field excitation; or, in other words, there are two values of excitation which result in the same armature current at a given load, and this is true of every load value within the range of the machine.

Letters on Practical Subjects

Communications intended for publication in this department must be received at this office not later than the 15th of the month prior to the date of publication.

Mr. Brown's Problem in Resistance Connections.

The enclosed diagram (Fig. 1) is submitted as a solution of Mr. Brown's problem in switch and resistance connections of last month. The double-throw switch is represented by *D* and the single-throw

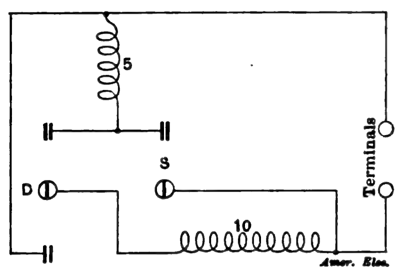

FIG. 1.—MR. BASS'S SOLUTION.

switch by *S;* the main-line connection is at *E.* Throwing the switch *D* upward and closing *S* puts the resistances in parallel and gives 3.333 ohms; closing *S* alone gives 5 ohms; closing *D* downward with *S* open gives 10 ohms and closing it upward gives 15 ohms.

Farmington, Ill. THEO. BASS.

[Exactly the same solution was supplied by Messrs. Frank W. Bone, of Reading, Mich.; F. S. Brewer, of Newark, N. J.; G. D'Eustachio, of Pittsburg, Pa.; F. R. Fishback, of Cleveland, Ohio; R. E. Gibbs, of Springfield, Wis.; F. W. Harris, of Wilkinsburg, Pa.; F. G. Hartwell, of Boston, Mass.; Frank Johnson, of Detroit, Mich.; Wm. Merrill, of Wilmington, Del.; A. Nelson, of Chicago, and Wm. O'Dwyer, of Detroit, Mich.—EDITOR.]

One solution of Mr. Brown's problem in connections is shown by the accompanying diagram (Fig. 2). Closing *S* alone obvi-

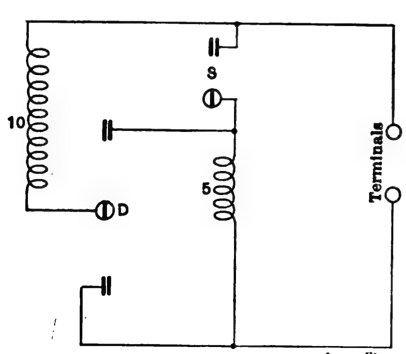

FIG. 2.—MR. SOUTHERLAND'S SOLUTION.

ously puts the 5-ohm coil in circuit; closing *D* downward with *S* open puts the 10-ohm coil in alone; closing *D* downward with *S* closed puts the coils in parallel and closing *D* upward with *S* open puts them in series. Arrangements such as this are frequently used in laboratory work.

Ithaca, N. Y. F. J. SOUTHERLAND.

[The same solution was furnished by Mr. James B. Dillon, of Louisville, Ky. It is like Fig. 1 so far as connections are concerned, the only difference being in the "lay-out" of the diagram.—EDITOR.]

Referring to Mr. Brown's problem in resistance and switch connections, I would

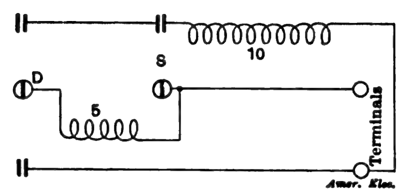

FIG. 3.—MR. GORILLA'S SOLUTION.

suggest the arrangement shown by the enclosed sketch (Fig. 3). If the single-throw switch, *S,* be closed alone it puts the 10-ohm coil in circuit with the main terminals; closing *D* downward alone puts in the 5-ohm coil; closing *S* and throwing *D* downward puts the two coils in parallel, and closing *D* upward alone puts them in series.

Ironwood, Mich. LOUIS J. GORILLA.

[The same solution was sent in by Messrs. John A. Kick, of Marietta, Ohio; A. W.

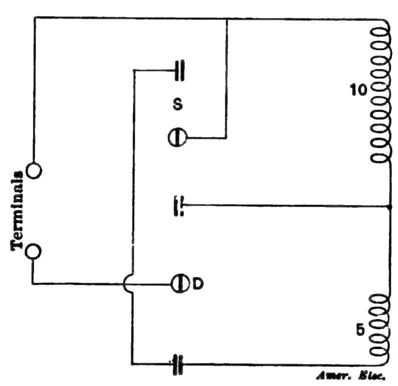

FIG. 4.—MR. RAINE'S SOLUTION.

Lawrence, of Flushing, N. Y.; E. S. Lincoln, of Brookline, Mass.; Geo. C. Ohlin, of South Omaha, Neb.; Gordon Weaver, of State College, Pa., and F. W. Cerny, Mesa, Ariz.—EDITOR.]

The enclosed arrangement of switches (Fig. 4) is submitted as a solution of Mr. Brown's problem last month. The two switches are mounted so that the blade of the single-throw switch, *S,* can be set into the jaws at one end of the double-throw switch, *D.* Closing both *D* and *S* upward puts the coils in parallel and gives 3⅓ ohms; then if *S* be opened, it leaves the 10-ohm coil connected to the main terminals alone; closing *D* downward puts the coils in series, and closing both switches downward puts the 5-ohm coil in alone.

Brooklyn, N. Y. CHAS. W. RAINE.

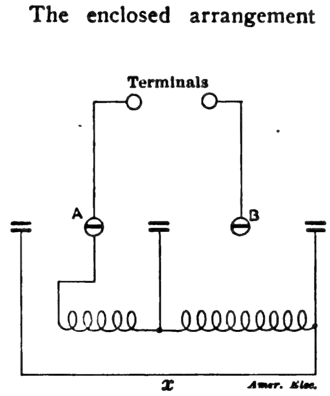

FIG. 5.—MR. STINSON'S SOLUTION.

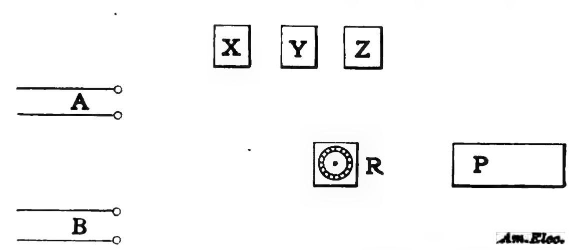
I suggest the accompanying diagram (Fig. 5) as a solution of Mr. Brown's problem in resistance connections. Two double-throw switch blades are mounted so that both of them align with the middle pair of jaws, only three pairs being used instead of the usual four. With both blades to the left, the coils are in parallel, giving 3⅓ ohms; with *A* open and *B* to the left, the available resistance is 5 ohms; with both blades to the right, 10 ohms are available, and with *B* to the right and *A* open, the coils are in series, giving 15 ohms.

West Baden, Ind. C. D. STINSON.

[Mr. Stinson's solution is open to the objection that with *A* closed to the left and *B* to the right the terminals would be short-circuited. Unpleasant results due to this accidental mishandling of the switches could easily be avoided, however, by inserting a suitable fuse in the cross-connecting wire, *x.*—EDITOR.]

Storage Battery Connections.

I submit herewith a problem in storage battery connections which may be of some interest to some of your readers. There are two supply circuits, *A* and *B* (see diagram) of different voltages for charging the portable cells, *P.* A regulating rheostat, *R,* is in series with either circuit and the portable cells, *P.* At certain times only a few portable cells are to be charged, and three other large capacity cells, *X, Y* and *Z,* are used to make up the proper voltage for the charging current. The circuits must be so arranged that either one, two or three of the large cells can be placed in series with the portable cells and the charging current. A switch is to be provided so that when the three large cells are charged their current can be turned into one or two of the portable cells through the regulating resistance, *R.* The large capacity cells are all the same size, also the portable cells.



PROBLEM IN STORAGE BATTERY CONNECTIONS.

If one of the large capacity cells becomes charged more than the other two the connections for discharging it need not be shown. These cells are to be cut out when enough portable cells are charging to ob-

tain the proper voltage. Only common switches are to be used and as few of them as possible.

BROOKLINE, MASS. E. S. LINCOLN.

A Bell and Relay Problem.

In a large building are distributed 15 vibrating bells and 18 push buttons. In the office is a shutter relay and two 32-c.p. incandescent lamps. Current to operate the relay and bells and to light the lamps is taken from a 110-volt circuit, but the full circuit voltage is not applied to the terminals of the bells for obvious reasons. It is desired to connect up the bells, push buttons, relay and lamps in such manner that when the shutter is raised the lamps will light and all of the bells will ring; this condition continues until one of the push buttons (any one of the 18) is pressed, which drops the shutter and extinguishes the lamps. The dropping of the shutter, of course, stops the ringing of the bells. No specially arranged bells are allowable; all of them must be the ordinary vibrating kind. I should like for readers of this paper to suggest the proper method of connecting up the apparatus to obtain the results described.

Washington, D. C. CHAS. W. PETRY.

Mr. Hardwick's Window Lamps.

The accompanying diagram (Fig. 1) solves the problem presented by Mr. Hardwick last month, if we disregard a slight inconsistency in his statement of the proposition. He says that "normally every lamp in the two windows is turned on by each switch," and further on he says that "nothing unusual was noticed until plug No. 4 burned out." This would indicate that all the lamps were controllable by either switch before the plug burned out. But, "with plug 2 out and the rest in, *A* operates half the lights and does not change them." The conditions would surely be the same if *B* were left open and the plug 2 either in or out; therefore, it is evident that with all the fuses in and in proper condition, if *B* were open only half the lamps could be lighted by closing *A*.

By tracing the connections of the diagram and comparing with Mr. Hardwick's list of results obtained under the different conditions of fuses and switches mentioned in his letter they will be found to agree.

Reading, Mich. FRANK W. BONE.

[In justice to Mr. Hardwick it should be explained that his original letter read "every *other* lamp in the two windows," etc. By some unfortunate mischance the word "other" disappeared in the printing office.—EDITOR.]

Mr. Hardwick's faulty connections were no doubt as shown by the enclosed diagram (Fig. 1), which gives all of the combinations he mentions. The error was due to the attempt to use a common return from each window. Fig. 2 shows the proper method of wiring the lamps. With this arrangement the fuses will protect the circuits without giving rise to puzzling combinations.

Newark, N. J. F. S. BREWER.

[Messrs. Bone and Brewer having furnished identical solutions, the one diagram (Fig. 1) has been used for both. The solution agrees exactly with Mr. Hardwick's diagram, which was sent in with his letter. —EDITOR.]

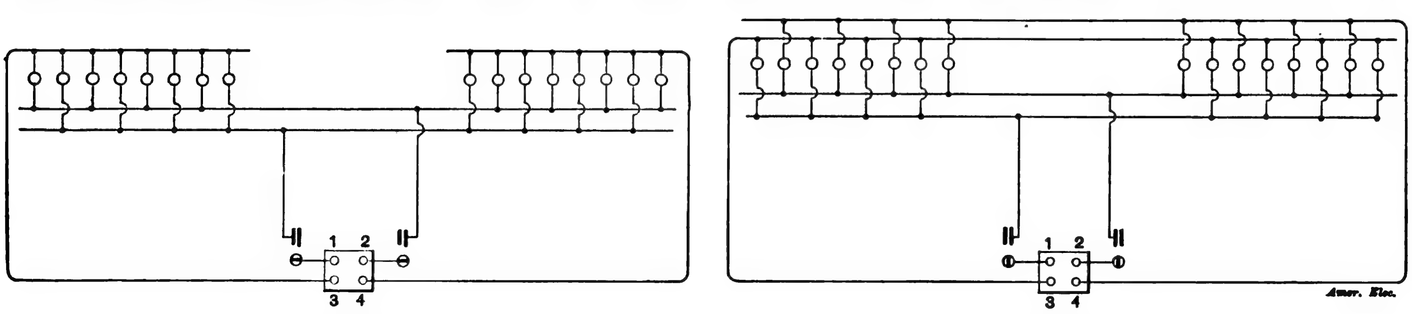


FIG. 1.—SOLUTIONS TO MR. HARDWICK'S PROBLEM IN FAULTY CONNECTIONS.—FIG. 2.

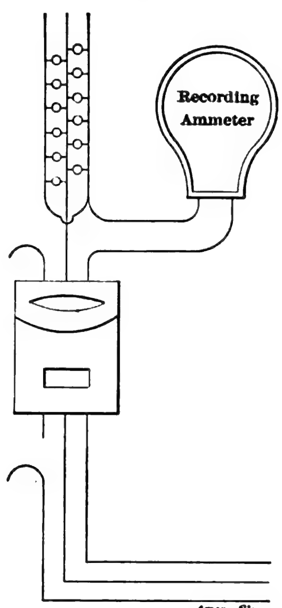
Mr. Vogel's Excessive Current Consumption.

I was surprised not to find in the April number any solution of my excessive meter bill problem, and submit herewith some additional facts, which I hope will be of interest. The company made a test for one week with a Bristol recording ammeter, and under this test the bill amounted to $4.68. At this rate the bill for the month would have been about $18, but the bill rendered was for $28. During the week of the test, the system was connected up two-wire fashion temporarily, as shown by the accompanying sketch. This appears to show that with the two-wire arrangement less current is used than with the three-wire. I should appreciate very much any suggestions that readers of this paper may make regarding the discrepancy.



EXCESSIVE CURRENT CONSUMPTION.

Philadelphia, Pa. J. C. VOGEL.

[It is hoped that Mr. Vogel's peculiar experience will incite some of our readers to an analysis of it. We may say, however, that an ammeter is a poor criterion of power consumption. Meter bills are for kilowatt-hours, not ampere-hours, and though the voltage may not vary greatly, it does not necessarily average up at the value assumed in computing power from the reading of a recording ammeter.—EDITOR.]

Another Telephone Problem.

There are three ordinary bridging telephone sets on a metallic circuit, and it is desired to add standard switches connected up so that any one of the three stations can ring up either one of the other two alone; in other words, the signaling part of the equipment is to be changed from party-line bridging to selective ringing merely by adding switches of regular construction and the necessary connections. The ground may be used as part of the signaling circuits, but not for talking. I should like the readers of the AMERICAN ELECTRICIAN to suggest solutions of the problem.

Helena, Ark. R. N. TURNER.

Switch Connections for Dimming Stage Lights.

Some years ago I had occasion to provide means for dimming an equipment of stage footlights, and having no rheostat handy, I had to figure out some method of quick manipulation by which the lamps could be connected either in parallel for ordinary illumination or in two groups in series with each other for dimming. The arrangement shown by the enclosed sketch (Fig. 1) was adopted, and it has given the best of satisfaction in the place where it was first installed, as well as in many other theatres where I have used it since that

time. Used in connection with a dimmer rheostat it provides a given range of con-

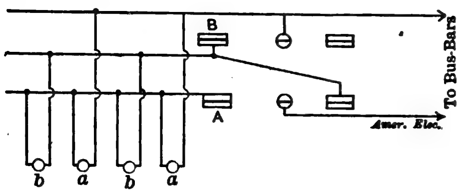


FIG. 1.—STAGE LIGHT CONNECTIONS.

trol with much less resistance in the dimmer than would be required otherwise. By making the jaws *A* longer than the jaws *B*, the lamps, *a*, *a*, can be kept lighted while the other lamps are extinguished.

Paragould, Ark. Thos. G. Van Sant.

[Fig. 2 shows a very similar arrangement which has been used for the purpose described by Mr. Van Sant, and also for testroom work. It consists of a double-throw, double-pole switch, to which are added a single pair of jaws and a corresponding extension of one blade. The only advantage

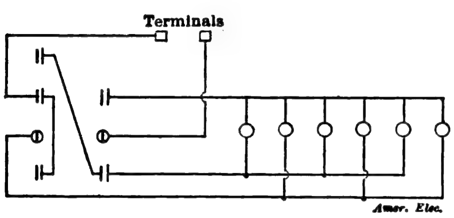

FIG. 2.—STAGE LIGHT CONNECTIONS.

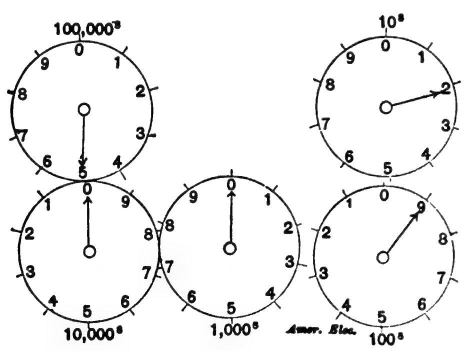
over the arrangement of Fig. 1 is that when the switch is open the distributing wires are all "dead."—Editor.]

Another Meter Reading Problem.

I have been interested in the tricky meter readings which have been published in this department, and recently struck the one shown by the accompanying diagram. I sub-



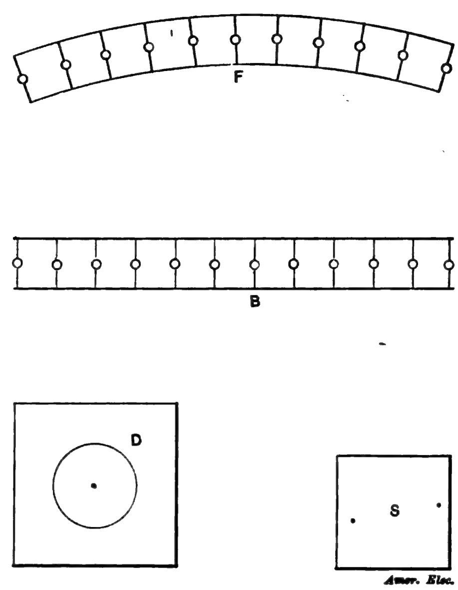
TRICKY METER READING.

mit it for the consideration of other readers.

Greensburg, Pa. Wm. W. Deighmiller.

Problem in Stage Light Connections.

Perhaps the accompanying problem will be of interest to other readers: I had it to solve some time ago. The group of circles, *F*, represents the footlights of a stage; the group *B*, the border lights; the box, *D*, is a dimmer, and the square, *S*, one or more switches of standard construction. The problem is to connect up these so that either group of lamps can be thrown either di-



MR. CONVERSE'S PROBLEM IN STAGE LIGHTING.

rectly on the supply main or through the dimmer, and both groups can be similarly controlled together; in other words, so that either or both groups of lamps can be burned at full candle-power or dimmed, separately or simultaneously.

Chicago, Ill. J. D. Converse.

An Induction Motor Trouble.

Some time ago I installed a 40-h.p. three-phase induction motor on a 60-cycle circuit, with a compensator for starting, the rotor being of the squirrel-cage type. Recently it refused to start up, even with the belt off. I tested the outside connections carefully, found them all right, and dismantled the motor. The rotor bars were solidly connected, and the stator winding tested out absolutely clear and symmetrical. With the current off, the rotor turned freely in the bearings, and the latter were not worn a particle—at least, not enough to be measurable. Putting it back together, it simply hummed and stood still. Finding it impossible to get the machine to run, it was returned to the builders, who supplied another one in its place after subjecting the obstreperous one to every test possible. Very recently I had exactly the same experience with a 50-h.p. machine of the same type. I have not been able to learn what the trouble was with either of them, and would appreciate it if some of your more experienced readers could suggest an explanation.

Brantford, Ont. A. C. Lyons.

Mr. Clarke's Station Trouble.

Noticing that no explanations were offered in last month's paper as to the cause of the trouble described by Mr. L. R. Clarke in the March number, I submit the following suggestions:

Mr. Clarke says he cannot load the 90-kw. generator without its dragging (that is just what it is doing). If he will increase the speed at the engine governor of the 90-kw. machine until it takes its proportional part of the load, and then strengthen the field current until he gets the smallest amount of idle current possible, this trouble will be corrected. The reason the distant station takes more load when the load comes on the railway generator is that the speed at the main station drops and the 90-kw. machine picks up the load. The speed of the exciter has nothing to do with it, provided it will generate the required voltage and supply the requisite exciting current.

Mr. Clarke does not say what kind of governors are used at the two stations, which is very important. Each station should have a very sensitive governor if the stations are to take proportionate parts of the load, otherwise the idle current and power factor will be changed so often that the power from each station cannot be recorded by the ammeter.

South Windham, Me. B. H. Elkins.

Mr. Shadbolt's Telephone Difficulty.

Referring to W. H. Shadbolt's telephone difficulty, which appears in the April issue of the American Electrician, I submit the following explanation, which is simply an example of the application of Ohm's law. Assume, for the sake of clearness, that we have a circuit of twenty telephones, all in perfect working order, that the line has no resistance whatever, and that it requires one ampere to ring each bell, each bell having a resistance of twenty ohms. It is evident that by Ohm's law the drop across one bell will be 20 volts ($E = I \times R$, or $E = 1 \times 20 = 20$).

Now, assume that the generator in use is just capable of giving twenty amperes at a pressure of twenty volts. From the above it is clear that the resistance across the whole line will be one ohm (all bells being connected in parallel).

Now, suppose that, in consequence of the poor ground established by the rods driven into sandy loam, and by the ground being frozen, we have an additional resistance, at the particular stations, where the trouble occurs, of two ohms each. When we ring up from either of these stations there is an outside resistance to ring through of 3 1-19 ohms, instead of one, and this will allow

only $\frac{20}{3\,1/19} = 6\,16/29$ amperes to pass into

the outside circuit. Since it would require 20 amperes to ring all the bells, and there are only 6 16/29 amperes flowing in the circuit, it is perfectly clear why the bells will not ring.

On the other hand, if one tries to ring up from one of the other stations, having, as assumed before, a ground of no resistance, when the current reaches any of the trouble stations it will have a resistance of 22 ohms

to pass, and with a pressure of 20 volts a current of 10/11 ampere would be allowed to flow. This current being so close to the required amount, would, without a doubt, ring the bells. The values which I have used are, of course, not those required in actual service, but I assumed them simply to make the explanation clearer.

W. H. MIDDLETON, JR.
Prince Bay, N. Y.

I beg to offer the following solution of the telephone problem stated by Mr. Shadbolt in your April issue:

Suppose, for convenience, that but one telephone of the twenty on the line has a ground rod driven in dry, sandy soil, and call it the "A" telephone. The other 19 telephones with ground connections to well pipes may be designated as "B" telephones. A good 1600-ohm polarized telephone ringer will operate with not less than 15 volts at its terminals, and this gives a current of $\frac{15}{1600} = 0.0094$ ampere. This means that a 1600-ohm ringer requires at least 0.0094 ampere to operate it. An ordinary telephone hand generator when turned at the usual rate generates approximately 75 volts. Neglecting line resistance, there is a pressure of 75 volts across the "A" telephone when one of the "B" telephones is signaling, and this voltage will send 0.0094 ampere through $\frac{75}{0.0094} = 7978$ ohms; $7978 - 1600 = 6378$, which means that the earth connection at the "A" telephone may present a resistance as high as 6378 ohms and still pass enough current to ring the "A" bell, thus accounting for the fact that the "B" telephones can ring the "A" bell.

Since each 1600-ohm ringer requires to operate it at least 0.0094 ampere, each generator must give out to the line at least $19 \times 0.0094 = 0.1786$ ampere in order to ring the other 19 bells satisfactorily. Suppose the earth connection at the "A" telephone had a resistance of 6378 ohms, the maximum resistance which would permit the "A" bell to be rung. Then, even ignoring the generator resistance, the 75 volts of the ringer would send out only $\frac{75}{6378} = 0.0117$ ampere to the line, instead of the 0.1786 ampere necessary to ring all of the bells of the "B" telephones. This makes clear the failure of the "A" telephone to ring the "B" bells.

Cleveland, O. R. S. MUELLER.

In regard to the telephone difficulty of W. H. Shadbolt, as printed in the April number, I submit the following explanation: In the first place, we know that dry sand, and also dry ice, are non-conductors. Hence in winter we can count on no grounding surface above the frost line. As moist sand is a poor conductor, the amount of surface connection between the conductor and the sand governs the amount of current which can be passed from the rod, so when we cut off the surface above the frost-line, and allow for the gradual drying of the soil below, during the winter, we find the difficulty is simply a lack of surface connection. For proof of this statement take an ordinary battery jar, fill it with moist sand, insert two battery zincs some distance apart, connect these in series with a generator and try passing current through the sand under different loads. To regulate the surface connection, slightly withdraw the zincs. The sand acts similar to a water rheostat. A connection which will ring one bell apparently as well as ever and which is sufficient for conversation will not necessarily ring nineteen times as many in parallel. Where it is inconvenient to obtain a connection with permanent moisture, as in the case of the well pipes, if the grounded conductors are soldered to buried copper plates much less difficulty will be experienced.

Mapleton, Conn. RALPH E. SPAULDING.

Mr. Shadbolt's trouble is due merely to the fact that his ground connections are poor, so that while the ringing and talking current from any one station to the main station may be sufficient, the ground resistance is too high to permit sufficient current to flow from the main station to all of the others in parallel.

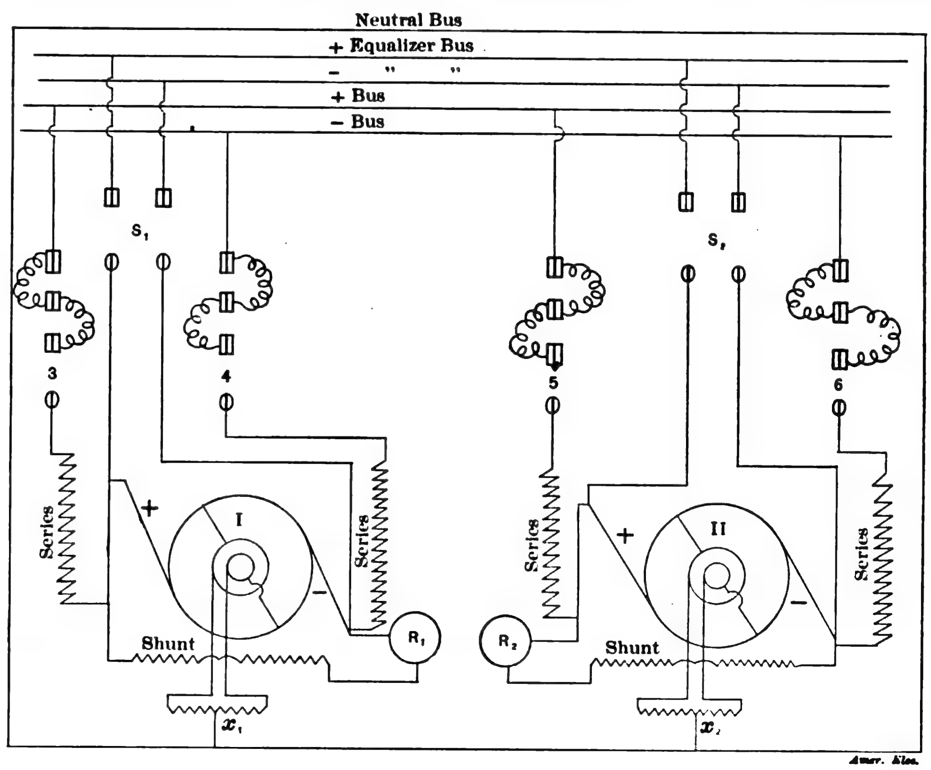
West Baden, Ind. C. D. STINSON.

Three-Wire Generators in Parallel.

Enclosed please find a somewhat tardy solution of Mr. Malcolm's problem in "Connecting Three-Wire Generators in Parallel," which appeared in the November (1904) number of your paper, and escaped my attention until recently. Referring to the diagram of connections, I and II are the three-wire generators, and X^1 and X^2 are the alternating-current compensators connected with the neutral bus-bar as shown. The equalizer switches, S^1 and S^2, of the machines 1 and 2, respectively, are double-pole switches, while switches 3, 4, 5 and 6 are single-pole switches of the style used in the field circuit of an alternator, resistance coils being connected between the stationary parts of each switch. When one generator is operating and it is desired to run the other in parallel with it, the voltage and speed of the incoming machine are properly adjusted, and its equalizer switch is then closed, as usual. The main switches, 3 and 4 or 5 and 6, as the case may be, are then put on together and slowly. None of the measuring instruments are shown, but it is an easy matter for any one to connect them in. The shunt winding is connected across the brushes, a short shunt.

I trust the solution is not too late for consideration.

Brookline, Mass. E. S. LINCOLN.



THREE-WIRE GENERATORS IN PARALLEL.

Faulty Generator Connections.

A peculiar occurrence, which took place recently at the Cudahy Packing Company's plant, Kansas City, Kan., may bear relating. The plant consisted of one 200-kw. Crocker-Wheeler machine and one 350-kw. machine, but owing to increasing demand for power a new 300-kw. was purchased. Space being limited in the engine room it was found necessary to move the switchboard and also on account of high water to raise it 15 feet. Accordingly, work was commenced early one Sunday morning with the intention of finishing before dark. The switchboard is a five-panel slate board, with

eight power circuits and two lighting circuits, each protected by circuit-breakers. The generators are 250-volt, compound-wound machines operated in parallel and connected by the usual equalizer. When everything was declared ready, the larger machine was started, but contrary to expectations it failed to pick up.

A thorough search was instituted at once, a magneto and bad language being freely used. It was discovered that the equalizer and series leads were crossed, but when these were set aright only 3 or 4 volts resulted. The small machine was then tried and proved all right. After another examination the lead wire coming from the generator field winding was found to be connected to the same bus-bar as was the jumper on the generator terminal board. Correcting this proved of no avail, and separate excitation was then resorted to, which had the desired effect. This should have been a hint of impending trouble.

The voltages were equalized and the machines thrown together; there ensued a flash, the 200-kw. circuit-breaker opened, and the load was all thrown on the larger machine. Carefully adjusting their voltages it was again tried, with the same results. Apparently one machine had been reversed, and the large machine was selected as the one by observing the light thrown by the arc lamps. The field wire leading to the board and one of the voltmeter wires were soldered together, and when this was changed it reversed the voltmeter connection. Then the series and armature leads were changed, also the field and voltmeter wire, and conditions brought back to normal. Had the leads been properly tagged before disconnecting, all trouble would have been obviated. Owing to the fact that they had to be lengthened and shifted around two or three times in cramped quarters, mistakes were easy.

These are the amphibious machines spoken of in the September, 1904, issue of the American Electrician, having passed through two floods, both of several days' duration. They are to-day apparently as good as new.

Kansas City, Mo. C. E. Bryson.

Water Tank Gauge.

When water storage tanks of about 5000 gallons capacity are located one hundred feet or more overhead it is not a very easy matter to keep accurately informed as to the depth of water on hand. When the tank is not very high and located so that the engineer can readily see it, a float with cord attached, operating on a scale outside of the tank is satisfactory; but when the tank is 150 feet or 300 feet, as in the case of the Deering Harvester Works, this arrangement is quite impracticable. The sketch herewith shows an arrangement made use of to enable an engineer to tell directly from the engine room, the height of water in a tank. A ¼-inch pipe is run from the tank to the ground and then continued about a foot underground to the engine room, where it connects with the mercury gauge shown to larger scale by Fig. 2. A piece of 2-inch pipe about four feet long plugged at both ends has one end connected to the ¼-inch pipe from the tank while the other end is connected with the vertical pipe as shown. The upper end of this vertical pipe is connected to a glass gauge 18 inches long, one end being open to the air. Through a small plug in the top of the reservoir mercury is poured and the valve in the ¼-inch tank connection opened, which forces the mercury up into the glass tube. The principle of the arrangement is evident. Since mercury weighs 13.5 times as much as water, about seven feet is required to balance the 100 feet of water from the tank. The 18 feet of depth in the tank would then vary the column of mercury 15⅜ inches, making a foot in the tank correspond to about ⅞ inch on the scale of the gauge, which is a convenient amount. It should be remembered in making such a gauge that the height of the column in the vertical pipe does not represent the entire mercury pressure, since the height in the reservoir drops slightly as the column rises.

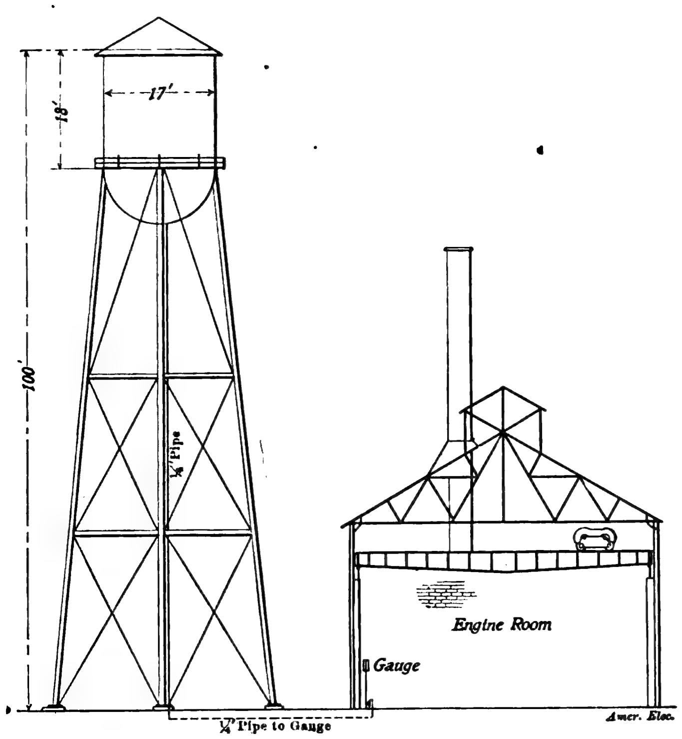


FIG. 1.—WATER TANK AND POWER HOUSE.

If d = depth of tank in feet,

A = area of reservoir,

a = area of vertical pipe in gauge,

s = length of scale in inches, representing d feet,

then in filling the tank from zero to the d point, the mercury in the vertical tube rises s inches, the mercury in the reservoir drops $sa \div A$, giving a total increase of $s + (sa \div A)$, or $s\,(A + a) \div A$. Equating this to the difference of pressure from the tank gives $12\,d \div 13.59 = s\,(A + a) \div A$ and $s = (12\,d \div 13.59) \times [A \div (A + a)]$, or depth of one foot water on gauge scale equals $.8836\,A \div (A + a)$ inches. In this case where the reservoir was 2 inches in diameter and the tube about ¼ inch the ratio of the areas was 1 to 64, consequently the gauge divisions were very nearly .8836 inches.

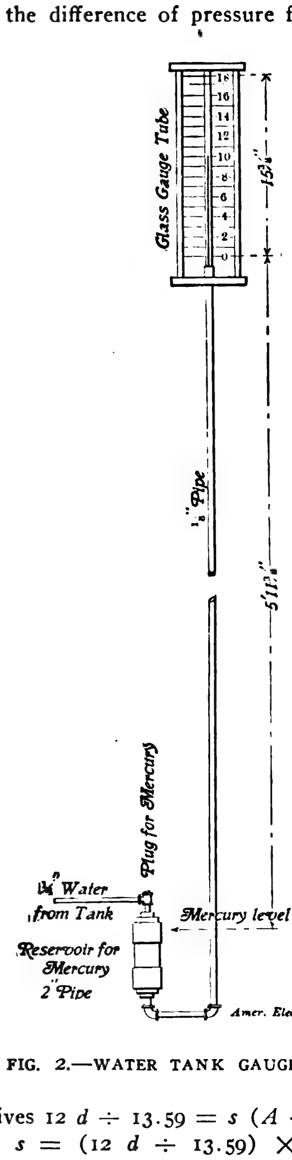

FIG. 2.—WATER TANK GAUGE.

Phoenix, Ariz. John D. Adams.

Questions and Answers

Inquiries not accompanied by the name and address of the inquirer, will not receive attention.

Is the tantalum lamp on the market in this country, and if so, where can it be obtained? H. E. B.

No; it is manufactured in Germany only, and no agency has been established in this country so far as we are aware.

What is the significance of the letter *j* used by Steinmetz in alternating-current calculations? B. C. B.

It is merely an operator to indicate vector addition or subtraction instead of algebraic computation.

Where is the best place to locate the fusible plug in an upright submerged flue boiler? O. F. S.

If you mean the ordinary vertical tubular boiler, the crown sheet is the proper place for the plug.

Where can I obtain the rubber tube specified in "Electrical Designs" for the 6-in. spark coil? C. H.

From any maker of hard rubber, such as the Goodrich Company, at Akron, Ohio, or any large dealer in such goods.

What causes a compound-wound generator to decrease its voltage as the load increases, the load being within the maximum capacity of the machine? H. A. S.

Either the shunt strip across the series field terminals is too short or the series winding is connected up backwards and is opposing instead of assisting the shunt winding.

A small shunt-wound machine wound for battery current runs fairly well as a motor, but will not operate as a dynamo, even at double its normal speed. It has a "polar" armature with 8 coils. What is probably the trouble and what the proper remedy? E. G.

The field winding probably requires more current to excite it fully than the armature is capable of delivering. There is no remedy.

Which is better for transmitting heavy alternating currents, a solid or a stranded conductor? (2) What size should be used for 200 or 250 amperes? S. B. F.

Stranded conductor. (2) That depends largely on the distance and the allowable drop, but under the Fire Insurance Rules rubber-covered conductors carrying 200 amperes must be not smaller than 200,000 circular mils cross-section; for 250 amperes, 300,000 circular mils would be required.

Can I supply 110-volt lamps from a 220-volt direct-current circuit? (2) How can a compound-wound generator be made to increase its compounding effect? J. R. W.

Not without using a dynamotor or a motor-generator between the supply line and the distributing mains. (2) By lengthening the shunt strip across the terminals of the series winding, provided the machine is not operating in parallel with others. If the shunt strip is already at the limit of its adjustment, another one of higher resistance must be substituted.

What is the best construction for an alternating-current magnet? (2) What size and weight of magnet would be necessary to lift 20 pounds? (3) Would the lifting power of an alternating-current magnet be affected if the magnet were located in an iron pipe or casing? S. R.

The core and all other parts of the magnetic circuit must be thoroughly laminated; otherwise, the construction is the same as for direct current. (2) We have no data for such a magnet and cannot undertake to design apparatus. (3) Not if the magnet is of the iron-clad type; otherwise, the magnet would be affected and the iron pipe would probably be heated.

Which of the circuit arrangements shown in Figs. 1 and 2 is preferable for two-station control? J. F. L.

Although Fig. 2 may require more wire, it is usually preferable for the reason that

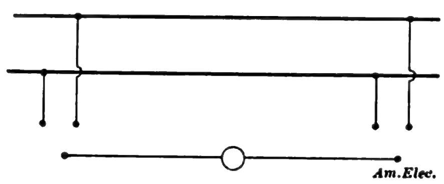

FIG. 1.

it can easily be changed to three or four-station control; Fig. 3 shows the change required to obtain three-station control.

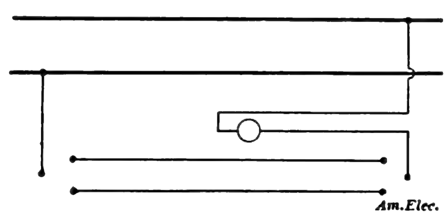

FIG. 2.

Moreover, Fig. 2 is not favored by the Underwriters because both sides of the circuit are carried to the switch.

Why will a direct-current motor start up with the field circuit open when the armature switch is closed? (2) What is the advantage in using six-phase rotaries instead of three-phase? (3) What is the voltage between any two adjacent taps of a six-phase rotary armature? J.

Because the field magnet after once being excited retains a weak magnetic polarity

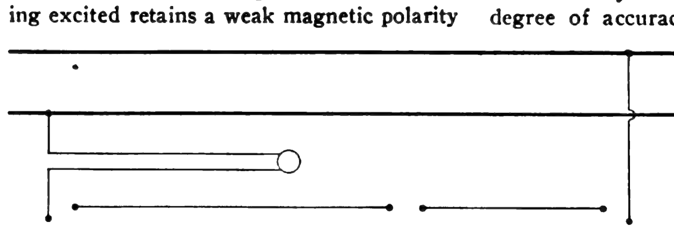

FIG. 3.

commonly known as residual magnetism. (2) Because there is less heating in the armature with a given output. Consequently, a greater output can be obtained from a given armature with the same amount of heating. (3) This depends entirely upon the voltage of the supply circuit. The voltage between any two adjacent taps of the armature is 0.354 of the direct-current voltage at the commutator brushes.

About what is the e.m.f. of a battery cell having copper and zinc elements and an electrolyte of dilute acetic acid or strong vinegar? (2) What is the electrostatic capacity per mile of a single No. 12 iron wire suspended 20 feet above the ground? (3) Can brass spiral springs which have lost their elasticity by being heated be restored? W. H. S.

From 0.2 to 0.3 volt. (2) The formula for capacity in microfarads per mile of length is:

$$\frac{0.0388}{\log \dfrac{4h}{d}},$$

in which h is the height above the ground and d the diameter of the wire in the same units. (3) No.

What is the best arrangement of circuits for supplying ninety series enclosed arc lamps, each requiring 80 volts at the terminals and the supply source being a 2200-volt alternator? (2) Can they be divided into four circuits, two of 22 lamps and two of 23, and the four circuits operated in parallel from the machine, or will the regulator not take up the difference in voltage? W. W.

We should prefer to divide the lamps into three circuits of thirty lamps each and increase the voltage of the machine, if this can be done without interfering with other circuits. If not, it would be better to run three circuits of say 25 lamps each and one circuit of 15 lamps, putting a permanent choking coil in the last circuit to take up most of the difference in voltage. Still another practical way would be to put in a 100-lamp series transformer and put all the lamps on one circuit. (2) Yes, with an independent regulator in each circuit.

What is the area of a circular mil? (2) What is the best formula for calculating the size of wire in a three-wire system? (3) What is the best method of computing the efficiency, required current and proper size of feed wire for a motor? (4) Will a shunt-wound motor run with its field winding open-circuited? G. H. L. R.

0.7854 square mil, or 0.0000007854 square inch. (2) Compute the size of the outside wires as though for a two-wire circuit of the over-all voltage and make the neutral wire the same size for interior work; for outside work make the neutral wire of half the cross-section of each outer wire. (3) The efficiency cannot be calculated with any degree of accuracy; the machine must be tested. The required current is ascertained by multiplying the horse-power by 746, dividing the result by the voltage, and dividing this latter result by the efficiency expressed decimally. For the proper size of feed wire, multiply the distance by the required current and multiply the product by 27; divide this last product by the allowable drop in volts and the result will be the cross-section of the wire in circular mils. The factor 27 includes the 25 per cent excess current for which the Underwriters require provision. (4) If the field magnet has much residual magnetism the armature will probably run at a very high speed without load; it will not carry an appreciable load.

AN AUTOMATIC SYNCHRONIZER.

To start alternators or rotary converters quickly and to bring them from a standstill to full running condition within the briefest possible period is one of the essentials of modern service, and, consequently, the ability to synchronize quickly machines which are to operate in parallel is a matter of importance. Incandescent lamps connected between the incoming machine and those running have been most frequently used in the past to indicate the phase relation by the pulsation of the light. This arrangement does not fulfill the requirements of modern service, however, as the phase difference is only roughly shown and, furthermore, there is no indication whether the incoming machine is running too fast or too slow, the fact of synchronism being indicated by dimming of the lamps, at which time the operator throws the generator switch. Moreover, during the time required to close the switch, the machines are liable to pass the point of synchronism, which would cause the surging of the currents between the machines. The introduction of the synchronism indicator marked a distinct advance in this branch of electrical practice. By its use it is possible to determine not only when there is a phase difference, but its amount, whether the incoming machine is too fast or too slow, and the exact moment when the machines are running synchronously and may be paralleled.

Although the synchroscope was a long stride in advance of the older methods of indicating synchronism, and still has wide general application, it has limitations in service, as it has no value further than visually indicating the conditions of the incoming machine, the throwing in of the switch being dependent on hand operation.

Accordingly, the Westinghouse Electric & Manufacturing Company has brought out an automatic synchronizing apparatus which is illustrated herewith. The apparatus comprises an electromagnetic synchronizer, an electromagnetic relay switch controlled by the synchronizer and a similar switch arranged to connect and disconnect the alternator or converter and controlled by the relay switch. The connections are clearly shown in Fig. 1. Fig. 2 is a view of the synchronizer and relay switch, with the hand switches which control their activity.

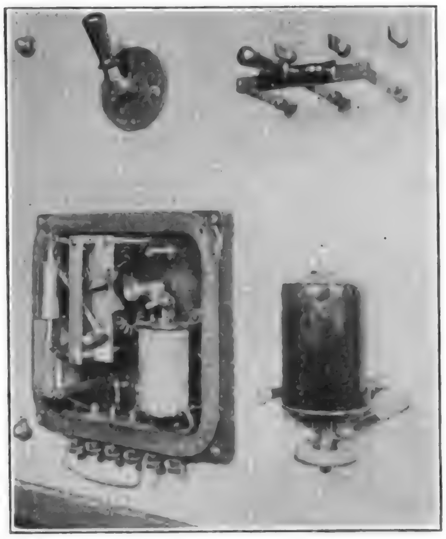

FIG. 2.—SYNCHRONIZER WITH RELAY AND CONTROLLER SWITCHES.

Referring to Fig. 1, the main switch is provided with two actuating coils, one for closing it and the other for tripping it and allowing it to open; presumably it is held closed by a latch and provided with a spring tending to open it when the latch is tripped, like a circuit-breaker. The hand-controlling switch when thrown to the right puts the main switch in condition to be closed by the relay switch; when thrown to the left it energizes the tripping coil and causes the main switch to open. The synchronizer switch merely connects the solenoids of the synchronizer to the potential transformers. One of these takes current from the bus-bars and the other from the incoming machine; when the incoming machine is sufficiently near to synchronism with the bus-bars to allow for the brief time required for the operation of the switches, the synchronizer closes the circuit of the solenoid on the relay switch, and that switch promptly closes the circuit of the closing coil on the main switch, which thereupon connects the incoming machine to the bus-bars. As just intimated, these consecutive operations require a very brief time period, and the synchronizer is calibrated to allow for this, so that when the main switch actually closes the incoming machine will have reached precise synchronism—unless the phase difference is varying too rapidly for successful paralleling, in which case the synchronizer will fail to close the circuit of the relay switch and thereby prevent miscoupling. This is accomplished by means of an ingenious attachment in the synchronizer which withdraws one of its contact brushes when the frequency of the incoming machine differs greatly from that of the active machines; as the difference in frequencies becomes less this device allows the synchronizer contacts to be closed ahead of the instant of synchronism by a margin corresponding to the time element of the magnetic switches.

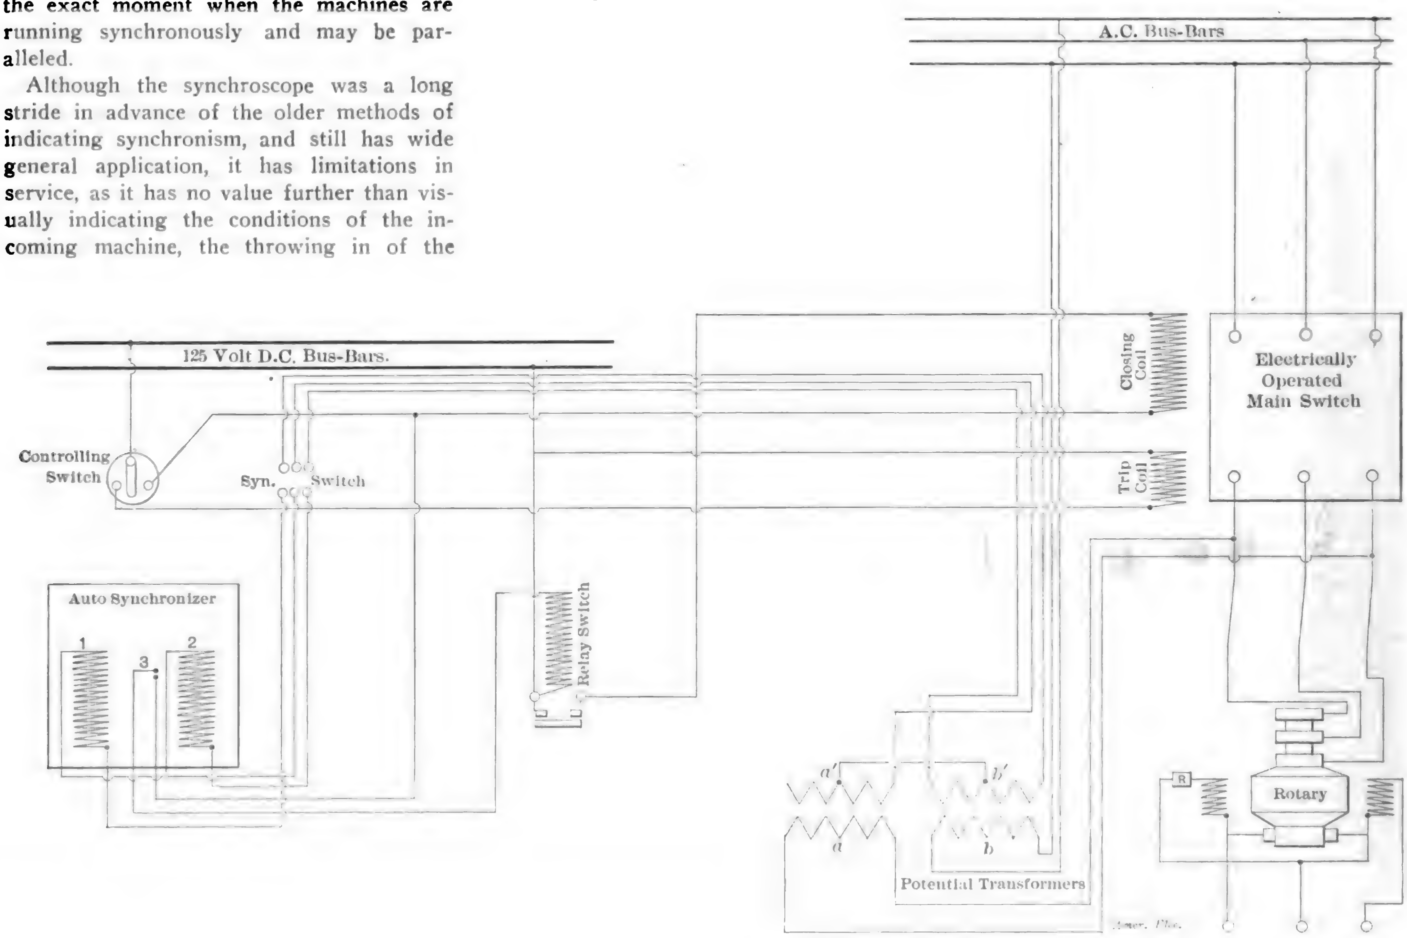

FIG. 1.—DIAGRAM OF CONNECTIONS FOR AUTOMATIC SYNCHRONIZER.

New Apparatus and Appliances

NEW HIGH-DUTY STORAGE BATTERY.

Fig. 2 herewith shows the Bijur high-duty storage battery brought out by the General Storage Battery Company, of New York City. The plates are of the Planté type; but while they retain the well-tried chemical combination of lead and sulphuric acid, they differ radically in design and results from forms hitherto known. Reference to Fig. 1 shows that the plate is made up of multiples of pure lead structures in the shape of gratings. These are welded in a stiff frame made of lead and antimony without the use of any extraneous material whatever. Space is provided at each end of the sub-element for expansion, and the make-up of the sub-element allows for lateral expansion also. During the formation process the oxide formed assumes an elliptical shape, and is said to lock itself securely in the diminutive rectangular cells. The formation, however, is such that a slot is left through the center of the oxide mass, so that the electrolyte can flow freely through it. The advantages claimed from following this mode of construction are, perfect diffusion, absence of deleterious sulphation, blistering or shrinkage and immunity from buckling. The makers maintain that the batteries may be charged with a potential of 2.4 to 2.5 volts instead of the usual 2.7 volts. Twenty per cent. greater capacity is claimed with about 10 per cent. more reserve lead for the same size of plate. Various sizes of plates are, of course, made; but these differ from the one shown only in the number of sub-elements combined, the sub-elements being of the same size in all of the various plates.

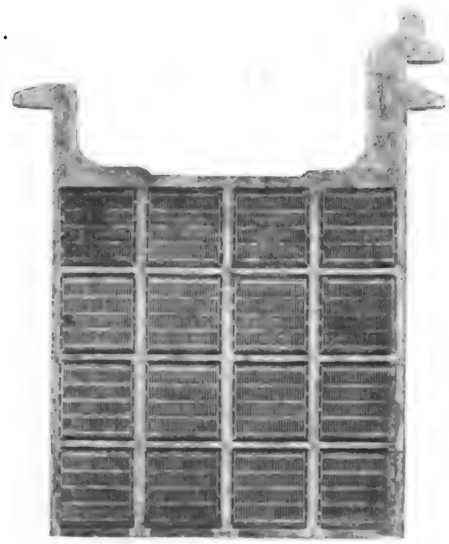

FIG. 1.—BIJUR UNFORMED PLATE.

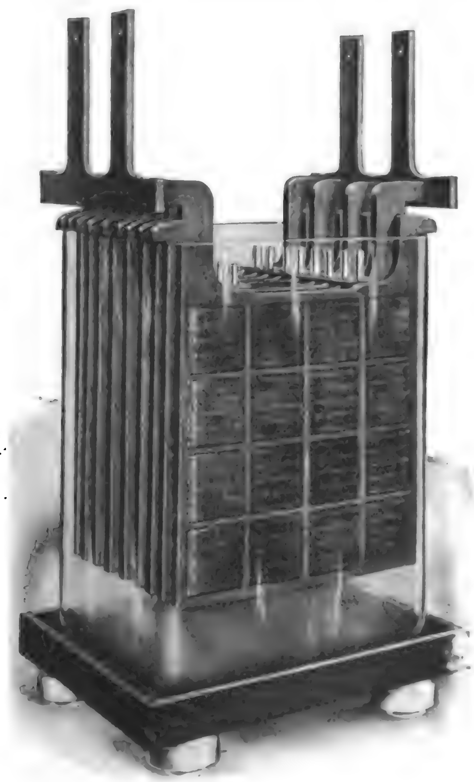

FG. 2.—BIJUR HIGH-DUTY STORAGE BATTERY.

OUTDOOR OIL SWITCH.

The demand for a serviceable outdoor type of oil switch adapted for use with alternating-current series arc lighting systems, for cutting out banks of transformers, isolating underground or overhead feeders and mains from main systems and operating inductive loads of all kinds, led the Westinghouse Electric & Manufacturing Company to design and place upon the market a switch to meet these requirements. It is a double-pole, single-throw switch, mounted in a weather-proof case, which may be easily attached to poles or cross arms in the case of overhead systems, or may be hung in manholes where underground systems are used. The essential features consist of knife-blade contacts submerged in oil and high insulation between poles and between frame and live parts. Knife-blade contacts are used as they insure the best contact for low temperature rise. Each jaw has a detachable arcing piece which takes the final break, thus preventing any possibility of arcing between the jaws and blades. These arcing pieces may be removed very easily when worn out or burned away. Suitable barriers are placed between the poles, which prevent the arcs from communicating. The switch weighs 40 pounds. When so ordered a special oil may be furnished with this switch which is especially suitable for use in cold weather, as it has a very much lower congealing point than any oil now on the market, which is otherwise suitable for oil switch work. One and one-half gallons are required to fill the tank. The switch has a maximum capacity of 200 amperes at 2300 volts.

FIG. 3.—OIL SWITCH.

SEMI-ENCLOSED MULTIPOLAR MOTORS AND DYNAMOS.

Fig. 4 illustrates one of the very complete lines of multipolar dynamos and motors now being manufactured by Bartz, Wygant & Brown, Hornellsville, N. Y. The field magnet yoke is of cast iron and the magnet cores are of round wrought iron cast-welded into the yoke ring. Pole shoes of cast iron are provided; these, of course, are removable to allow the removal of the magnet coils. The coils are machine-wound and insulated in the usual manner, and the armature coils are also form-wound and individually-insulated. The armature core is of the now conventional slotted type, built up of thin discs which are mounted directly on the shaft. The latter is of unusually large diameter, and therefore extremely stiff and strong; it is made of the best crucible steel. The bearings are of the ring-oiling type, and are provided with glass sight gauges and stop-cock drains. The commutator is of large diameter, built up under heavy pressure and insulated with carefully-gauged mica; the makers state that loose mica and high or low bars are unknown in their commutators. The brush-holders are of the reaction type, carbon brushes being used, of course; the current density at the brush faces is considerably lower than is usual in similar machines, giving a low temperature rise at this point. The dynamos are ordinarily compound-wound and the motors shunt-wound. The construction of the protecting wings on the frame is so clearly shown by the illustration as to require no comment.

FIG. 4.—SEMI-ENCLOSED MOTOR.

THE BARAGWANATH CONDENSER.

Fig. 5 herewith shows a sectional elevation of the Baragwanath condenser manufactured by William Baragwanath & Son, Chicago, Ill. The water is fed in the side of the condensing chamber, which it enters in a thin circular sheet which passes down through the contracted throat with such

velocity as to carry with it the air passing over with the steam and in the condensing water itself. A supply of 1½ gallons per indicated horse-power per minute is said to be ample. The throat is carefully bored its entire length. The water nozzle is adjustable, thereby admitting of close regulation of the water supply while still maintaining the circular form of the stream of water as it enters the condensing chamber, and ex-

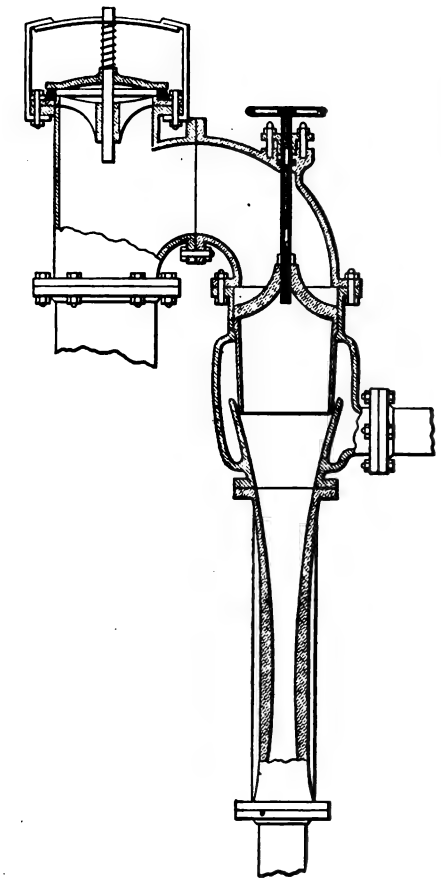

FIG. 5.—SECTIONAL VIEW OF BARAGWANATH CONDENSER.

posing the same large condensing surface. Even when nearly shut off the manufacturers claim there are no bare spots on the side of the condensing chamber, the circular sheet of water simply being thinner. The relief valve seats on a heavy molded rubber gasket, which is readily removable and is cushioned by a spring to take off the jar on the condenser when it lifts. The condenser is applicable to any purpose for which a vacuum is required. It is set at a height of 34 feet above the hot well and clears itself of the discharge water and air by gravity alone. The manufacturers claim that it will secure and maintain a vacuum ranging from 24 to 26 ins. ordinarily, and will syphon its own water safely up to 15 feet as a maximum. Any ordinary type of pump will answer as a supply.

ROCHESTER FAN MOTOR OUTFIT.

The Rochester Electric Motor Company, of Rochester, N. Y., manufacture the fan motor outfit shown by Fig. 6 herewith. The motors in the smaller sizes are bipolar, with magnet poles cast integral with the yoke or frame. In the larger sizes the motors have four poles, the frame being of cast iron and the pole pieces built up of punchings and bolted to the frame. In the bipolar machines the wires are wound directly into the insulated slots, the manufacturer finding that by this means more copper could be placed into the same sized slot than with the former coil. The four-pole machines are form wound. The brush

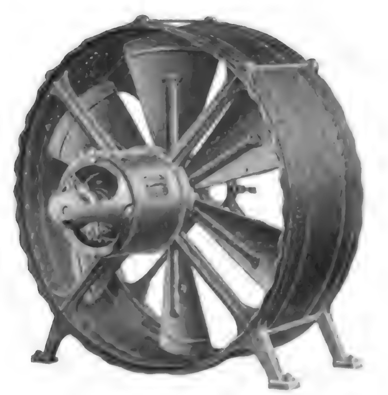

FIG. 6.—ROCHESTER VENTILATING FAN MOTOR.

holders are of the box type, two flat springs in the box providing ample carrying capacity without the use of a copper cable, and since the current density never exceeds 20 amperes to the square inch of brush contact, there is no heating or sparking. Unless otherwise ordered the motors are series wound for 115, 230 or 500 volts. The field magnet coils are wound on forms, heated, dipped into insulating varnish, baked and insulated with mica and tape. The bearings are of phosphor-bronze and flooded with oil by rings of large diameter and a special system of spiral grooving. The bearings are interchangeable for motors of the same size and the oil wells are of ample capacity. The curved blades of the fan have an expanding pitch and may be set to suit the conditions under which the fan is to operate. The shape of the blades is such that the passage of light is unobstructed. Every outfit is rigidly inspected and tested before shipment. The size of fans run from 18 to 96 inches in diameter and the speed from 800 to 2,000 r.p.m. The horse-power of the motors used ranges from ⅛ to 4 horse-power. The capacity ranges from 3,400 cu. ft. of air per minute to 6,300 cu. ft.

IMPROVED MOULDING FOR ELECTRIC WIRES.

The Improved Moulding Manufacturing Company, of Philadelphia, has brought out the type of wooden moulding for electric wires shown by Fig. 7 herewith. This moulding is designed to hold the wires in

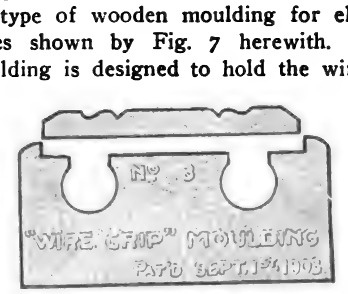

FIG. 7.—END VIEW OF MOULDING.

place without the use of nails or tacks until the capping can be nailed on. As is well known it is next to impossible to hold wires in the grooves of the ordinary moulding on ceilings and keep it there without the use of nails or tacks. The opening in the groove of the moulding shown is made so that the wire may go in easily, while the natural twist or kinkiness of the wire causes it to take such a hold in the groove that it cannot be shaken or hammered out.

ALCOHOL TORCH WITH ADJUSTABLE BLOW-PIPE.

The pocket-size alcohol torch shown by Fig. 8 herewith is made by the H. C. Roberts Electric Supply Company, of Philadelphia, Pa. Its novel feature consists of

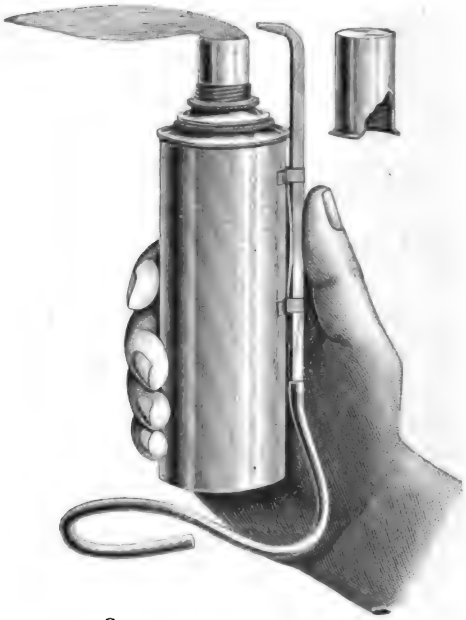

FIG. 8.—ROBERTS ALCOHOL TORCH.

the automatic arrangement for fastening and adjusting the air pipe and nozzle. Between the torch and air pipe a bow spring is inserted, which causes the air pipe to bind against the keepers. A slight pressure of the thumb, as indicated in the engraving, enables the user to adjust the nozzle by an upward or downward movement of the same finger.

ALTERNATING AND DIRECT-CURRENT GENERATORS.

The R. M. Cornwell Company, of Syracuse, N. Y., has recently added to its line of small machines, the "Wonder" alternator, which is a very interesting piece of apparatus. It is very desirable from the fact that all kinds of experiments can be performed that require an alternating current.

FIG. 9.—"WONDER" ALTERNATOR.

It is said to be the smallest alternating-current machine ever offered for sale, and has a laminated armature. All parts are interchangeable, and so arranged that they can be easily taken apart to show the general

construction throughout. The machine is designed for experimental purposes in schools and colleges. It has an output of 12 watts, and is wound for a number of different voltages. When operating the little machine as a generator the alternating current can be taken off one end and direct current from the other. The machine will also operate as a motor on the 110-volt, direct-current circuit, by using a lamp in series.

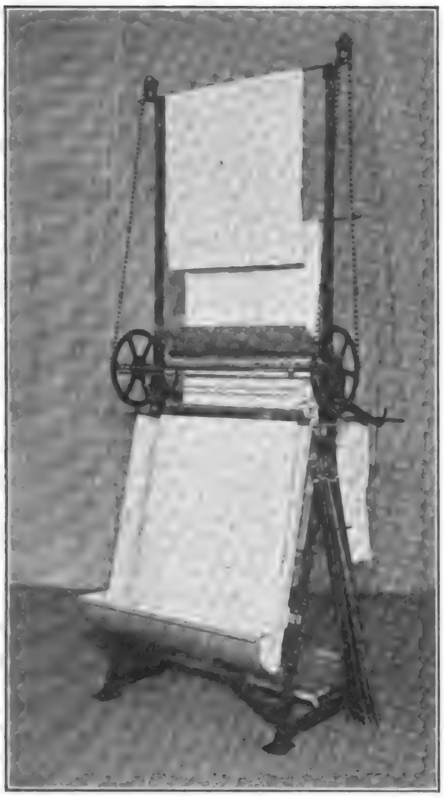

FIG. 10.—BLUE PRINT WASHING AND DRYING MACHINE.

BLUE-PRINT WASHING AND DRYING MACHINE.

The accompanying illustrations show a blue-printing washing and drying machine made by C. F. Pease, of Columbus, Ohio. This machine was designed for the purpose of reducing the cost of producing large quantities of blue prints and to do away with the large washing tanks and drying paraphernalia usually occupying a great deal of space in a blue-printing department. The washing of the prints is accomplished by a spray of running water flowing over the treated side of the paper only, removing the surplus ferro-prussiate in the quickest possible time. Prints are not soaked through as in the old process, as the water coming in contact with one side of the paper only and for but a short time leaves it in a condition to dry in about one-third of the time usually required. The print is placed on the drying rod before washing and remains there during the entire process of washing, wiping and drying. As it hangs in the washing tray on the drying rod, the water flows over the doubled print, half on one side and half on the other. The surplus water is removed by a device which wipes the print as it is moved upward out of the way on the drying chains. As the next print is pulled through the wiping device the previous print is carried still higher up and over the top until it is automatically stripped from the chains of the machine, falling into a drying rack, from which the dry prints may be removed as required. The construction of the machine is clearly shown in the illustrations. The frame is of cast iron thoroughly braced, and supports the washing, dripping and drying devices. The washing tray, guard and pan are made of galvanized iron and reinforced by malleable galvanized-iron fittings. The upper frame carries the small sprockets and chains and is made of iron tubing well braced and secured to the main frame of the machine. Screws are provided for adjusting the chain. The spray comes through brass tubing properly guarded by a copper shield to direct the spray where required. The drying rods are of maple and are provided with rubber separators.

FIG. 12.—MACHINE WITH AUTOMATIC SEPARATING AND DRYING RACK.

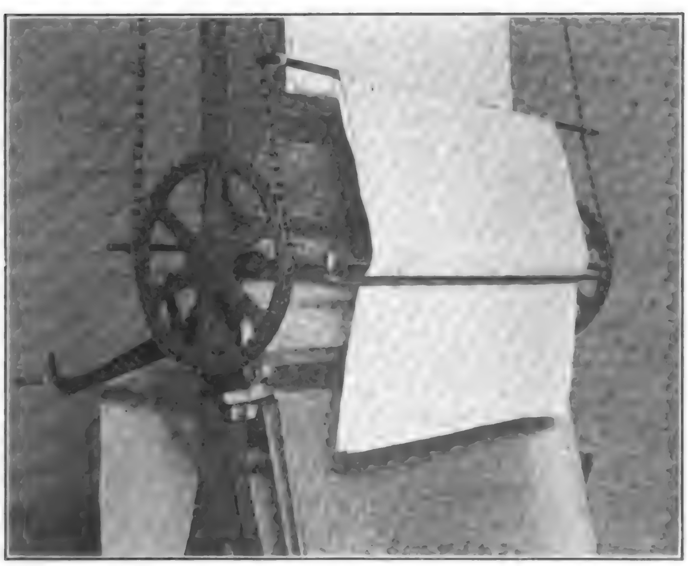

FIG. 11.—PRINT PASSING THROUGH WIPING DEVICE.

TRIAD FANS.

The Essex Electric Company, of Newark, N. J., has brought out the combination of fans shown by Fig. 13 herewith, known as the "Triad." The outfit consists of two fan motors mounted on a fixture that revolves while the fans rotate, and a governing fan above or below that is driven by the propeller action of the two fans. The power utilized in the revolution of the governing fan is transmitted through compound gearing. The fixture revolves on ball bearings, and requires no oiling or attention. The electrolier attachment is wholly independent and the fixtures and motors are dustproof. The oiling device is said to prevent the oil from spattering while the fan is revolving. At high speed the fixture revolves at 14 r.p.m., and the governing fan at a speed of 126 revolutions. The buzz fans revolve on the low speed at 1400 revolutions and on the high speed at 1800 revolutions. The revolution of the fixture may be stopped by tightening a thumb screw in the center of the fixture. The motors have a trunnion mounting, and are furnished with a two-speed switch.

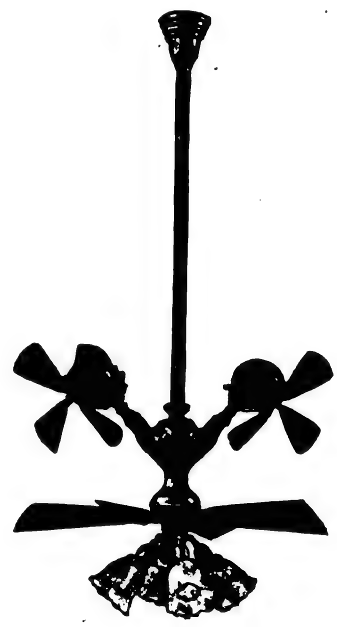

FIG. 13.—"TRIAD" FAN MOTOR.

WIRT ORGAN REGULATORS.

The Wirt Electric Company, of Philadelphia, Pa., has brought out a regulator for organ blowers where these are operated by electric motors. The regulator is connected by means of a cord to the bellows in such a manner that the upward movement of the bellows rotates the regulator switch and thereby adds resistance to the motor circuit,

reducing the speed. A counterweight acts to produce an opposite rotation, cutting resistance out of the circuit and increasing the speed of the motor. By this means an automatic regulation is secured whereby the proper amount of air in the bellows is maintained. The resistance material is a continuous ribbon wound without joint from one end of the rheostat to the other into the desired number of steps, each step making direct connection with its commutator segment. Mica is used solely for insulation purposes. The switch is a laminated brush of German silver which in

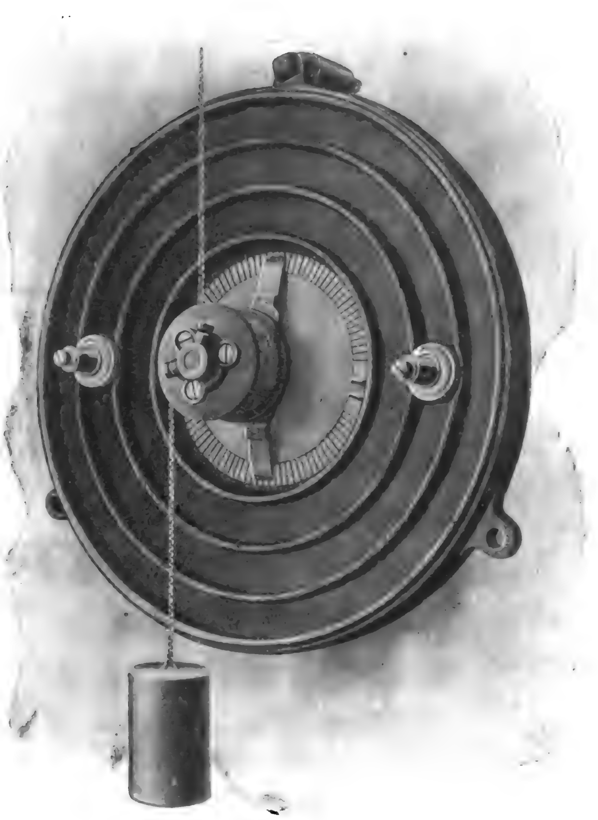

FIG. 14.—WIRT ORGAN REGULATOR.

contact with brass commutator bars gives a good running surface, fine contact and long life.

PRICE LIST WANTED.

Mr. J. S. Webster, electrical engineer for Farwell, Ozmun, Kirk & Co., St. Paul, Minn., is about to prepare specifications for the electrical equipment of a nine-story building which the firm will erect in the immediate future, and desires catalogues and prices on wiring materials, fittings, switchboard material and apparatus, panelboards, conduit fittings, electric fixtures, etc. At first current will be taken from the electric lighting company's mains, but a complete power plant will be installed later on.

TECHNICAL ADVERTISERS ORGANIZE.

The advertising representatives of a large number of concerns engaged in the manufacture of machinery and allied industries have formed an organization to be known as the Technical Publicity Association. The first annual meeting, dinner and election of officers was held in the rooms of the Hardware Club in the Postal Telegraph Building, New York, on April 27. An interesting address was delivered by Mr. E. P. Harris, well known as a broker of trade and technical journals.

OPENING OF THE MANILA STREET RAILWAY.

The first important work in the Philippine Islands to be completed since the beginning of American occupation is the Manila Street Electric Railway, which was formally opened Monday, April 10. For the past two years J. G. White & Co. have been engaged in the work of reconstructing the railways of Manila. Peculiar difficulties have been met and overcome and, where formerly there was a horse car line, with eight miles of track, built with forty-pound rail, there is now an electric system as complete as that of any city of similar size in the United States. The entire street railway system of Manila is controlled by the same syndicate, and it includes, in addition to the horse car line, a steam line running to the suburbs. Forty miles of track have been laid with 70-pound rails in the city and 94-pound rails in the suburbs. Municipal lighting privileges are also controlled by the White Company. The power will be supplied from the new power house just completed. The company operates its own printing plant, which is located in the car barn, and is used for printing time tables, circulars, tickets, etc.

THE NURNBERG VALVE-GEAR.

The Nurnberg Works in Germany desire it to be known that they use on their steam engines a trip valve gear built under their own patents (the Marx gear). On their gas engines they also use their own gear, with which the cut-off of the valve always takes place at the same time while the valve opens at different points, that is, at full load, sooner than at small loads, the time of opening being well graded. If the engine is entirely unloaded the valve opening point is so late that it coincides with the cut-off, so that the valve remains shut altogether. The opening point only is controlled by the governor, which has no effect upon the cut-off mechanism.

NOVEL INDUSTRIAL BENEFICIAL ASSOCIATION.

The shop employes of the Crocker-Wheeler Company, at Ampere, N. J., have organized a beneficial association which has a number of novel features. Every employe who pays ten cents a week to the association will be entitled to $10 a week for twenty weeks during incapacity through illness. If he dies his family will receive $100. The payment of twenty, thirty or forty cents a week entitles him to $15, $20 or $25, respectively, with death benefits of $150, $200 or $250. The plan went into effect April 3.

The company has offered to contribute an amount equal to the dues paid to the association. Thus if $6000 is paid yearly in dues, the income of the association will be $12,000. The company does not require representation in the association, which will be run entirely by the employes.

The president of the Crocker-Wheeler Beneficial Association is James Moore, who has charge of one of the big planers in the main bay of the shops. The other officers are Charles H. Brittain, vice-president; Geo. T. Owen, financial secretary; Frederick Maines, recording secretary, and William Lennox, treasurer.

FORCED DRAFT.

The argument formerly advanced against the use of forced draft instead of induced draft that it burns out the grates, seriously injures the boilers, and blows gas and smoke from the fire doors, is now seldom heard. The basis of this opinion, it is stated, originated in the experience of some engineers with plants equipped with fans operated at far above the proper speed. This was the result of installing (through ignorance) a fan too small for the work, and then forcing it above its normal speed in order to secure the desired air volume. As a consequence, instead of creating an ash-pit pressure of ¾ to 1¼ inches, which is all that is ordinarily required, the pressure was forced up to 5 or even 10 inches, with the attending objectionable results. In one instance the engineer complained of gas discharged from the fire doors, with incidental effects, and condemned forced draft out and out, although he was favorably disposed toward induced mechanical draft. Investigation showed that the fan was being operated at about 12 inches water pressure.

When forced draft is used, the air as it passes from the ash-pits to the combustion chamber is greatly reduced in pressure, owing to the resistances of the grates and the fuel. Coincidentally, the stack, even if a short one, tends to produce a partial vacuum in the furnace. As a result it is practically impossible to create under proper conditions more than a slight excess of pressure in the combustion chamber, and this should not be enough to force the gases out at the fire doors. Accurate knowledge regarding the proper application of the fan blower for this purpose will readily dissipate any false impression regarding forced draft, and should always be sought before making a decision either for or against it.—*Communicated.*

WESTINGHOUSE—GENERAL ELECTRIC.

Numerous rumors in financial and trade circles have been current during the past weeks to the effect that the Westinghouse and General Electric Companies are engaged in a trade war and that the patent agreement between the two companies has been broken. It is well known that the Westinghouse and General Electric Companies have exchanged patent licenses and under the agreement covering such exchange each company can freely use the inventions covered by patents of the other; but in other respects the two companies are active business competitors. The patent agreement was made in March, 1896, and is effective for fifteen years. In making use of the patent rights under the license each company has, however, relied upon its own experience in manufacturing and on the whole has designed and promoted its own apparatus, rather than to make a close copy of the other company's apparatus. The effect of the patent agreement has been eminently satisfactory to both the companies and their stockholders and customers. It has resulted in a total saving of about one million dollars yearly, which previously was spent in patent litigation and various other elements of time and expense. The expiration of the Tesla patents next month has stimulated competition among electrical manufacturers in the building of the induction type of motor. As a result of this the two large companies have each brought out a new type of induction motor embodying changes and improvements in the motor covered by the old Tesla patents, and which will be placed on the market at a material reduction in price. Several other electrical manufacturers are now in the market for induction motor orders and are prepared to make shipments. The expiration of the Tesla patents and the attention given this important epoch in the electrical industry by the concerns engaged in the manufacture of electrical apparatus has probably been at the bottom of the rumors to the effect that the working agreement said to exist between the two largest electrical manufacturers as to business harmony is about to be terminated.

WESTINGHOUSE CHANGES IN NEW YORK.

Westinghouse interests will occupy all but a small part of the nineteenth and twentieth floors of the new Trinity Building at 111 Broadway, New York, after May 1. The executive offices of the Westinghouse Electric & Manufacturing Company, which have for nearly twenty years been in the Equitable Life Building, at 120 Broadway, will be on the nineteenth floor of the new building, and the eastern sales offices of the Westinghouse Air Brake Company and the Westinghouse Traction Brake Company will occupy a large part of the twentieth floor. The law offices of Hunt, Hill & Betts, which have been for several years in the Equitable Life Building, will be on the twentieth floor of the new building, and the remaining part of the floor has been sublet to an engineering company.

The United States Electric Light Company, which was absorbed by the Westinghouse Electric Company shortly after the organization of the latter company, opened offices in the Equitable Life Building in 1878, and the building has been more or less a Westinghouse headquarters in New York for the past twenty-five years, and the New York office of Mr. George Westinghouse.

The New York sales offices of the Westinghouse Electric & Manufacturing Company will remain in the Hanover Bank Building at Pine and Nassau Streets, without change, and the New York office of the Westinghouse Company's publishing department, formerly at 10 Bridge Street, will be connected with them. The export offices of the electric company will continue at the same address, under the management of Mr. Maurice Coster, recently appointed to succeed Mr. F. B. H. Paine, and the office of Mr. Chas. S. Powell the new general agent of the electric company, will be connected with the sales and export offices. Messrs. Coster and Powell have arrived from Paris and from London to take up their new duties after long terms of successful service with Westinghouse interests abroad.

MACHINE TOOL MOTOR DRIVE.

At the convention of the National Machine Tool Builders' Association, held in Washington on April 11 and 12, the application of individual variable-speed motors for the driving of machine tools was discussed very fully. Mr. G. Herbert Condict, vice-president of the Electro-Dynamic Company, Bayonne, N. J., addressed the association on the subject and made the following points:

As to the advantage of the motor-driven tool over the belt-driven, it was pointed out that in the case of equiping a new shop a saving could be made in the initial cost of the power plant, owing to the fact that there will be less loss in the transmission of the power from the engine shaft to the shaft of the tool, and, therefore, a smaller power plant would be required. With the belt drive it had been practically demonstrated that the average loss in the shafting and belting amounted to at least 50 per cent. of the total power developed by the engine. This is due especially to the fact that when a belt is laced it is made as tight as possible in order to provide for stretching, and this causes undue loss of power by the excessive friction in the bearings as well as in the running of the belt itself. After the belts have run for some time they become loose, and there is a loss of power by their slipping. In the case of the line shafting itself, no matter how carefully the line may be put up in the first place, there will shortly be a certain amount of deflection, especially in a long and heavy shaft, which in time will cause a great loss in the shafting bearings, even if they are well lubricated.

In a system of electrical transmission, assuming that the shop is to be operated at say 75 per cent. of the generator capacity, so that good efficiency can be obtained from the generator itself, the loss between the engine shaft and the line will be about 6 per cent., the line loss 2 per cent. and the average loss in the motors about 17 per cent. There will also be a loss between the motor shaft and the shaft of the tool itself, where a single pair of gears or a chain drive is used of 5 per cent, or a total loss between the engine shaft and the tool shaft of about 28 per cent. Attention was called to the fact that the loss in the shafting and belting is practically a constant loss no matter whether the shop is operated at its full capacity or not, where the loss in the case of the electrical transmission varies practically with the power used. Instances were given of a plant which has been entirely equipped with individual motor drive, in which there was installed only one-half of the power capacity which had been calculated would be necessary in the case the shop had been designed for belt drive, and that this power plant had been operated on an average of only one-half of its actual capacity, thus showing that in this particular case only 25 per cent. of the power was required for running the shop with electrical transmission that had been estimated on for belt transmission.

Reference was made to a case in which a department of a machine shop was being examined, where the bulk of the tools were driven from a line of shafting, but one lathe was equipped with a variable-speed motor. A hot bearing occurred on the line shaft and shut down all tools run by the shaft and for 20 minutes 23 machines were idle, while the machinist on the motor-driven tool continued his work. As these shutdowns are liable to occur in the best regulated shop from various defects and troubles of shafting and belts, this item of saving is quite an important one.

NEW BOOKS.

SUCTION GAS. By Oswald H. Haenssgen. Cincinnati, Ohio: The Gas Engine Publishing Company. Cloth; 90 pages, 5 in. x 7 in.; several illustrations. Price, $1.00.

This little book should meet with a warm welcome from those interested in gas production and utilization for power purposes. It is a simple exposition of the methods and objects of producing suction gas and includes also data taken from tests made with this kind of gas plant in Europe.

ALTERNATING-CURRENT TESTING. By Fitzhugh Townsend. New York: D. Van Nostrand Company. Heavy paper; 32 pages, 5 in. x 8½ in.; 10 illustrations. Price, 75 cents.

The contents of this book comprise a synopsis of the course in alternating-current laboratory work which is given to the graduating classes in mechanical engineering at Columbia University. It is well prepared and covers much ground considering its mechanical size. The diction might be improved considerably in places, but the lapses are not wide enough to obscure the

author's meaning; moreover, the actual merit of the work greatly overbalances these small faults.

WEBSTER'S INTERNATIONAL DICTIONARY. (1900 revision, with additions.) Edited by W. T. Harris, Ph.D., LL.D. Springfield, Mass.: G. & C. Merriam Company. Sheep; 2350 pages, 8 in. x 11½ in. Price, $10.00.

This edition of the well-known Webster dictionary is undoubtedly the most complete work of its general kind thus far issued in a single volume. The 1890 edition was thoroughly revised in 1900, and a Supplement of 234 pages has been added to the main work. Our criterion of the character of the book naturally is the degree of correctness of its technical definitions, and all of these that we have taken the trouble to examine are astonishingly accurate and clean-cut in comparison with those usually found in general cyclopædic works of similar scope.

PERSONAL.

MR. L. E. JEANNIN has just established an electrical contract and supply business at Orlando, Fla.

MR. CHARLES DUCAS, formerly editor of the *Railroad Gazette*, has joined Mr. Ray D. Lillibridge in his business of technical publicity.

MR. A. L. ROGERS, formerly with the Stirling Company, has joined the staff of the Platt Iron Works Company's New York Office at 93 Liberty Street.

MR. RALPH D. MERSHON, the well-known consulting electrical and mechanical engineer, has removed his office to 11 Pine Street, New York. Mr. Mershon's Montreal office remains in the Street Railway Chambers.

MR. GEORGE B. DAMON, for some time manager of the New York office of the Wellman-Seaver-Morgan Company, Cleveland, Ohio, has been transferred to an important position in the engineering department at the home office.

MR. W. K. PALMER, Kansas City, Mo., recently completed plans and specifications for a hydraulic electric plant to be located on the Ninnesoah River. The plant is to be built for the Kingman (Kan.) Light & Power Company.

MR. D. B. RUSHMORE, formerly of the engineering staff of the Stanley Electric Company, Pittsfield, Mass., has been transferred to the Railway Engineering Department of the General Electric Company, Schenectady.

MR. CHARLES H. WILLIAMS, president of the Northwestern Electrical Association, has resigned the superintendency of the Madison Gas & Electric Company, Madison, Wis., to accept the general management of the Wisconsin Light & Power Company, La Crosse, Wis.

MR. GEORGE W. EDGE, eastern salesman for the Trumbull Electric Company, Plainville, Conn., has been put in charge of the company's mail order department and catalogue work, and is busily engaged in organizing a complete follow-up system.

MR. W. A. STADELMAN, who was for ten years the General Eastern Agent of the Brown Hoisting Machinery Company, has been appointed to the same position with the Wellman-Seaver-Morgan Company, Cleveland, Ohio. Mr. Stadelman's headquarters are at 42 Broadway, New York.

MR. RICHARD DEVENS, who has for several years been connected with the European office of the Brown Hoisting Machinery Company, Cleveland, Ohio, has been appointed manager of that company's New York office to succeed Mr. Stadelman, whose resignation is noted in this column.

MR. A. C. BUNKER, formerly connected with the Stanley Electric Manufacturing Company's Pacific Coast department, and more recently with the John F. Kelly Engineering Company, has joined the engineering staff of the Crocker-Wheeler Company in the alternating-current department.

MR. A. E. FLEMING, who for a number of years past has represented the Nernst Lamp Company in the capacity of District Sales Manager, with headquarters at Chicago, recently resigned his position with that company to become the Manager of the Nernst Lamp Sales Department for the Canadian Westinghouse Company, Ltd., Hamilton, Ont., and he is now actively engaged in his new duties.

MR. H. D. CRITCHFIELD, General Counsel and Sales Manager of the Automatic Electric Company, Chicago, has recovered from a long siege of serious illness and returned to his office. Mr. Critchfield was attacked by appendicitis in January and underwent an operation at the Chicago Hospital on February 1. While convalescing he was seized with pneumonia, from which he has just recovered as noted.

MR. J. H. HALLBERG, the well-known arc-lighting specialist, recently delivered an extremely interesting illustrated lecture before the Electrical Engineering Society at Columbia University on "The Application of Electricity to Heavy Freight and Trunk Line Railroads." Mr. Hallberg described in detail all of the various systems which have thus far been proposed and experimented with for trunk line service; also his own railway system for transmitting power by single-phase current and utilizing it by means of polyphase induction motors on the cars.

MR. C. E. L. BROWN, of the well-known engineering establishment of Brown, Boveri & Co., Baden, Switzerland, has been appointed consulting electrical expert for the Administrative County of London and District Electric Power Company, which is planning to construct three electric generating plants to supply the whole of London and those suburbs which are controlled by the London County Council. The generating units are to be the largest thus far constructed, consisting of turbine-generators each of 10,000 kilowatts normal output and 20,000 kilowatts maximum output ability.

TRADE PUBLICATIONS.

TELEPHONES. The Dean Electric Company, Elyria, Ohio.—Folders Nos. 1 and 2, devoted respectively to the Dean "compact type" wall telephone sets and portable desk sets.

GAS ENGINE DYNAMOS. Rochester Electric Motor Company, Rochester, N. Y.—Circular No. 52, devoted to the Rochester dynamo built for gas-engine drive in sizes ranging from 1 to 20 kilowatts.

PANELBOARD CABINETS AND COVERS. The H. O. S. Engineering Company, Newark, N. J.—An eight-page folder containing tabulated data and illustrations of H. O. S. panelboard cabinets and covers.

WATERWHEEL GOVERNORS. Lombard Governor Company, Ashland, Mass.—Bulletin No. 103, devoted to an illustrated description of the Type N Lombard governor which was recently described in this paper.

THE METAPHONE. Electric Utilities Company, New York.—A catalogue of standard size containing an illustrated description of the metaphone, which is a special type of the interior intercommunicating telephone system.

DIRECT-CURRENT MOTORS. Burke Electric Company, Erie, Pa.—This is Bulletin No. 3, devoted to the semi-enclosed "Type A M" Burke motor. The bulletin is well illustrated and the descriptive matter is very complete.

RICKARDS CORLISS ENGINES. Corliss Engine Works, Philadelphia, Pa.—A book of standard catalogue size, containing a brief illustrated description of the Rickards-Corliss steam engine and a number of testimonials from users.

NEW YANKEE DRILL GRINDER. Wilmarth & Morman Company, Grand Rapids, Mich.—Catalogue No. 90, of standard size, devoted to the well-known New Yankee drill grinder, which is now built in some twelve or fourteen styles.

MAGNETO WATCHMEN'S CLOCKS.—The Holtzer-Cabot Electric Company, Boston, Mass.—Bulletin No. 152-A, containing an illustrated description of the Holtzer magneto clock and station apparatus for recording watchmen's movements.

STEAM PUMPS. The Canton Pump Company, Canton, Ohio.—This is catalogue No. 16-B and contains brief descriptions, profusely illustrated, of the Canton simplex and duplex steam pumps for boiler feeding, condensing plants, fire service, etc.

THE HUNT NOISELESS CONVEYOR. C. W. Hunt Company, New York.—Catalogue No. 053, containing a profusely illustrated description of the Hunt noiseless conveyor in all its details and numerous illustrations of typical plants which have been installed.

SUMMER COMFORTS. The Fort Wayne Electric Works, Fort Wayne, Ind.—This is publication No. 5007 and is devoted to a detailed description of the fan motors built by this company. The pamphlet is artistically executed and of unusually attractive appearance.

CHURCH LIGHTING BY ELECTRICITY. Nernst Lamp Company, Pittsburg, Pa.—A handsomely executed brochure setting forth the merits of the Nernst lamp for lighting church interiors and containing several illustrations which go to vindicate the claims made in this direction.

SIMPLICITY THEATER DIMMERS. The Cutler-Hammer Manufacturing Company, Milwaukee, Wis.—The 1905 catalogue of Simplicity dimmers, containing a very complete illustrated description of this apparatus, with a list of users. The catalogue is well executed and attractively bound.

FAN MOTORS. Westinghouse Electric & Manfacturing Company.—Folders Nos. 4044 and 4045, the former being devoted to the Westinghouse direct-current fan motors and the latter to the alternating-current machines. Both are of vest pocket size and extremely artistic in execution.

TELEPHONE AND ANNUNCIATOR PRACTICE. Electric Gas Lighting Company, Boston, Mass.—Bulletin No. 7, containing illustrations and brief descriptions of a large number of telephone switchboards, annunciphones and intercommunicating telephone systems installed by the E. G. L. Company.

ELECTRIC LIGHTING SPECIALTIES. Faries Manufacturing Company, Decatur, Ill.—Catalogue No. 11, containing illustrations and brief descriptions of the very comprehensive Faries line of special and standard electric light fixtures, shades, reflectors, clusters, canopies, nipples, nozzles, connectors, etc.

A LITTLE MORE LIGHT. Ewing-Merkle Company, St. Louis, Mo.—This is publication No. 25, containing a great deal of valuable practical information on telephone subjects, such as line construction, estimates of installation costs, exchange operation, petitions for franchise, the organization of a company, etc.

ELECTRIC LIGHTING SPECIALTIES. The Bryant Electric Company, Bridgeport, Conn.—This is the 1905 catalogue of Bryant goods, which line comprises lamp sockets of all types, wall receptacles, rosette sockets, flush receptacles, ceiling rosettes, snap and knife-blade switches, arc lamp hanger boards and cutouts, cutout plugs for Edison plug fuses, attachment plugs, etc.

VULCAN SHAKING AND DUMPING GRATES. A. D. Granger Company, New York. Bulletin No. 4, devoted to the shaking and dumping grates built by the Granger Company. The catalogue is well executed and well illustrated. It includes also illustrations and brief descriptions of the standard forms of boiler fronts, grate bearers, etc., built by the company.

GENERAL INFORMATION BUREAUS AND TICKET OFFICES. New York Central & Hudson River Railroad.—This is No. 38 of the Four-Track Series of publications and contains in an extremely convenient form a full list of the Information Bureaus and city ticket offices of the

New York Central lines throughout the world, together with illustrations of most of the principal offices.

INDUCTION INTEGRATING WATTMETERS. Fort Wayne Electric Works, Fort Wayne, Ind.—A reprint of a very interesting paper read by Mr. A. A. Serva before the Colorado Electric Light, Power & Railway Association. The paper is liberally illustrated and contains an exposition of the principles of the induction wattmeter and a description of the type of meter built by the Fort Wayne Company.

GENERAL STATUTES RELATING TO FRANCHISES. H. M. Byllesby & Co., Chicago, Ill.—This is a compilation made by a well-known Chicago attorney for Messrs. Byllesby & Co. and published for complimentary distribution by that firm. It gives the general statutes of the various states and territories relating to the use of streets and highways by street railway, gas, water and electric light companies.

STOMBAUGH GUY ANCHOR. W. N. Matthews & Bro., St. Louis, Mo.—A very attractive illustrated catalogue entitled "Anchors That Hold," and containing a brief description of the Stombaugh guy anchors and wrenches, illustrations of the methods of installing the anchors, a report of very complete tests of the holding capacity made by Prof. Carpenter, and a number of testimonial letters from users of the anchor.

CABLE CLIPS AND HANGERS. The Chase-Shawmut Company, Newburyport, Mass.—An illustrated folder, designated Bulletin No. 30 and containing brief illustrated descriptions of the Boston cable clip, which the company has been making for several years, and the Shawmut marlin cable hanger, which is a new product designed for use in places where the Boston cable clip might be too expensive.

WATERTUBE BOILERS. E. Keeler Company, Williamsport, Pa.—This is the 1905 catalogue of this company; it is of standard size, opening at the end and finely executed. The catalogue contains illustrations and brief descriptions of the Keeler watertube boiler and settings and the Metesser superheater, together with illustrations of some notable boiler plants and practical remarks on the subjects of workmanship, supports and settings, superheated steam, circulation, lignite fuel and bagasse.

THE "STANDARD" AUTOGRAPH AND PICTURE BOOK. The Robbins & Myers Company, Springfield, Ohio.—This is an extremely ornate publication of the loose-leaf type, containing illustrations of the well-known Standard motors and fan-motors built by the Robbins & Myers Company, together with fac simile reproductions of strong testimonial letters from users of the R. & M. apparatus. The book also contains illustrations of notable installations, as well as the component parts of the latest types of Standard motors.

STIRLING. The Stirling Company, New York. —This is an elaborate publication on steam engineering topics, containing 248 pages 7½x10½ inches and profusely illustrated. The mechanical work on the book is in keeping with the highly valuable character of its contents, the latter by the way, relating only in part to the Stirling boiler, boiler setting and stoker. Impurities in boiler feed water, moisture in steam, superheated steam, fuels for boilers, the utilization of waste heat, the analysis of flue gases, and principles of steam piping are a few of the subjects treated in the book. It is an unreservedly commendable piece of work.

BUSINESS NEWS.

SHULTZ BELTING COMPANY has removed its New York office from 113 Liberty Street to 111 Chambers Street.

DIELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., has established a New York office at 138 Liberty Street.

THE NEW YORK SAFETY STEAM POWER COMPANY has removed its headquarters from 115 Liberty Street to the Engineering Building, 114 Liberty Street, New York.

EWING-MERKLE ELECTRIC COMPANY, St. Louis, Mo., reports that the month of March was one of the best that it has had since its entrance into the electrical jobbing field in April, 1903.

THE COLONIAL FAN & MOTOR COMPANY has removed its executive offices from Ravenna to Warren, Ohio, where it is in much better position to handle orders and make prompt shipments.

THE TROY ELECTRICAL COMPANY, Troy, N. Y., has improved the appearance of its line of voltmeters and ammeters (described in this paper last February) by substituting a faceplate of much handsomer design; the movement remains unchanged.

THE GEORGE W. LORD COMPANY, Philadelphia, manufacturer of boiler feed-water compounds, has shipped abroad since the first of this year 50,000 pounds of compound to India, 30,000 pounds to Liverpool, Eng., and 30,000 pounds to London.

GENERAL INCANDESCENT ARC LIGHT COMPANY, New York, calls attention to the fact that the order for the 4000 or more Wright demand meters which the Boston Edison Company is to install, as noted in our last issue, was placed with it.

THE PITTSBURG GAGE & SUPPLY COMPANY, Pittsburg, Pa., has been awarded the contract for a large oiling system to be installed in the new plant of the National Tube Company, Lorain, Ohio. The White Star oiling system will be installed of course.

THE BLISS ELECTRICAL SCHOOL, Washington, D. C., reports that at present there are on its rolls students from more than thirty states and that electrical positions are filled by its graduates in nearly every state of the Union and in many foreign countries.

THE STIRLING COMPANY, builder of the well-known Stirling boiler, has removed its executive offices from the Pullman Building, Chicago, to the Trinity Building, New York. The offices in the Pullman Building will, however, be continued as Western sales offices.

JOHN L. GLEASON, Jamaica Plain, Mass., has arranged with the Central Electric Company, Chicago, and the Commercial Electric Supply Company, St. Louis, to carry in stock a supply of his molding boxes and to act as his exclusive representatives in their respective territories.

NORTHWESTERN ELECTRIC EQUIPMENT COMPANY, St. Paul, Minn., reports that it has been admitted to membership in the National Jobbers' Association and has gone into the electrical supply business on a large scale. The company's stock of supplies is said to be one of the most complete in the Northwest.

THE ELECTRIC GAS LIGHTING COMPANY, Boston, Mass., has recently supplied "Rotokoll" telephone switchboard outfits for the State Normal School, Chicago, the Naugatuck (Conn.) High School and is building a similar switchboard for the Brockton (Mass.) High School. They have also recently equipped a number of factories with similar outfits.

AMERICAN CIRCULAR LOOM COMPANY, Chelsea, Mass., states that the National Board of Fire Underwriters has cancelled the specifications of Rule 50-C of the National Code, referring to the construction of flexible tubing, and has restored to the list of approved fittings "Circular Loom" of the type manufactured by the American Company during the past twelve years.

THE ARNOLD COMPANY is the new name of the progressive concern heretofore known as the Arnold Electric Power Station Company, the headquarters of which are in the Marquette Building, Chicago. The change in name is the only one which the company has undergone; it will continue along the lines heretofore followed, under the direction of its energetic president, Mr. Bion J. Arnold.

C & C ELECTRIC COMPANY has removed its general offices from 143 Liberty Street, New York, to the works at Garwood, N. J., this step having been found expedient on account of the necessity for close touch between the general offices and the factory and the difficulty of maintaining this under the great increase in business. A branch office will be maintained, however, at 149 Broadway, New York.

ALLIS-CHALMERS COMPANY, Milwaukee, has removed its general offices from Chicago to Milwaukee in order to be in closer touch with the works. The company has decided to begin immediately an extension to the Milwaukee works for the manufacture of electrical machinery of all kinds, and the construction of steam turbines, hydraulic turbines and gas engines. This extension, it is estimated, will cost about $3,000,000.

THE AMERICAN DIESEL ENGINE COMPANY, New York, announces the closing of contracts recently for Diesel engine installations as follows: Baldwin Locomotive Works, 450 horse-power; Gorham Manufacturing Company, 450 horse-power; Citizens' Electric Light & Ice Company, Lebanon, Ind., 345 horse-power; Baxter Springs (Kan.) Electric Company, 75 horse-power;; the Effingham (Ill.) Light & Power Company, 240 horse-power.

THE DODGE COAL STORAGE COMPANY, New York, has acquired from the United Telpherage Company the exclusive right to manufacture and sell the telpherage systems hitherto manufactured and marketed by the latter company in the United States. All current correspondence, plans, drawings, etc., have been transferred to the Dodge Coal Storage Company, New York, and future communications concerning telpherage outfits should be addressed to that company.

THE NATIONAL ELEVATOR COMPANY, Honesdale, Pa., and New York City, under the new management has closed a number of important contracts recently for elevators in large apartment houses in New York, as well as installations in buildings of other classes. Mr. H. F. Guerney is president of the reorganized company, and Mr. R. E. Carichoff, the well-known elevator specialist, is consulting engineer. The company recently established new offices at 400 West 23d Street, New York.

FREDERICK PEARCE COMPANY is the style of a new corporation, chartered under the laws of the State of New York, which has succeeded to the business of Frederick Pearce. Mr. Pearce is president of the new company; his son, Charles F. Pearce, vice-president; and Mr. George H. Tamlyn, secretary and treasurer. The company will continue the well-known lines of telephone, telegraph and electric light apparatus previously built by Mr. Pearce, and will considerably enlarge the scope of the business.

THE STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY, Rochester, N. Y., reports a flourishing business in its line of work, having closed contracts recently for a large number of switchboards. Among these is a contract with the United States Telephone Company, of Columbus, Ohio, for a tollboard which is said to be the largest one ever built for an independent telephone company. The contract includes all of the equipment necessary for the board, together with a test board, a chief operator's desk, a switching section and a messenger call box.

BROWN-CORLISS ENGINE COMPANY, Corliss, Wis., recently received an order from the National Tube Company for two 38-in. and 70-in. x 60-in. tandem compound rolling mill engines for especially heavy work at the McKeesport plant. This important contract was secured by reason of the satisfactory performance of a 19-in. mill engine formerly built by the Brown Company. The company now has twenty-six engines going through its shops, including the 20,000,000-gal. pumping engine for the city of Milwaukee, which was mentioned in this column a few months ago.

THE MURRAY IRON WORKS COMPANY, Burlington, Ia., is constantly receiving strong testimonials to the merits of its well-known Corliss engines. The company has bound in convenient form fac simile reproductions of a large number of these letters and classified them according to the character of work done by the engines. Book No. 1, for example, contains the letters relating to engines used in electrical work; book No. 2, those relating to engines used by railroads, mines, cotton mills, lumber mills, and similar establishments; No. 3, flour mills and elevators, and No. 4, oil mills. All of the testimonials are unqualifiedly favorable.

CLEVELAND ARMATURE WORKS, Cleveland, Ohio, has established an engineering department based on its extensive experience in the repairing of electrical machinery during the past ten years and a careful analysis of the design and construction of the various lines of machines built in this country. The new department, by reason of the company's unique experience, is well qualified for getting up special designs for dynamos, motors, lifting magnets and other electrical apparatus, revising existing lines, and supplying all of the preliminary calculations and data for any concern proposing to establish an electrical manufacturing business.

MARINE ENGINE & MACHINE COMPANY, Newark, N. J., announces that the Armington & Sims engines, which it recently made arrangements to manufacture, will be built in sizes ranging from 10 to 3000 horse-power, in both horizontal and vertical types, in side-crank and center-crank forms, simple and non-condensing, in high, medium and slow speeds, with single valve and with Corliss valves, and adapted to direct-connection or other modern requirements. Mr. Gardner C. Sims has acquired an interest in the company's business and becomes its general manager. As noted in last month's issue, the engines will be built under Mr. Sims' personal direction.

THE NILES-BEMENT-POND COMPANY has announced the purchase of a large factory property at Nicetown, Philadelphia, formerly occupied by the Cresswell & Waters Company, for an addition to its Philadelphia plants. This property will be greatly improved and equipped with modern facilities for use as a foundry for the Bement-Niles Works branch of the company at 21st and Callowhill Streets, and also the Niles Crane Works branch at Meadow and Mifflin Streets. This increase of facilities is one of the many important developments that have been made by the Niles-Bement-Pond Company recently, owing to the recent large increase of business and many large contracts which have been taken. The combined plants in Philadelphia, regardless of the three other large plants operated by the company at Hamilton, Ohio; Plainfield, N. J., and Hartford, Conn., will now employ about 2,000 men.

NATIONAL ELECTRIC COMPANY.—The First National Bank, Milwaukee, having had assigned to it about two-thirds of the capital stock of the National Electric Company to secure loans, has taken over the control of the latter company. John I. Beggs, Charles F. Pfister, Frederick Vogel, Jr., J. H. Van Dyke, Jr., all First National Bank directors, have been elected directors of the National Electric Company, replacing S. W. Watkins, president, F. H. Bigelow, chairman of the board, F. C. Randall, director, vice-president and general manager, and Gordon Bigelow. Former directors, A. N. McGeoch and B. T. Becker, remain on the board. John I. Beggs has been elected to and accepted the presidency of the company and will direct its affairs. The business of the company will be actively continued and all contracts will be promptly completed. The indebtedness of the company is now being ascertained and, when known, a meeting of the creditors will be called to consider the best plan to protect all creditors and promote the future welfare and progress of the company.

GENERAL ELECTRIC COMPANY has just brought out two new lines of motors, one a direct-current and the other an induction motor. The new direct-current line ranges from 20 to 185 horse-power, and the machines are all six-pole, with laminated magnet poles bolted to a steel yoke ring and journal brackets of the ring and spider type; these motors are provided with sliding bases and may be mounted on the floor, wall or ceiling. The alternating-current line ranges from 1 to 35 horse-power, and differs from the well-known line hitherto built chiefly in the form of frame employed. Instead of the usual circular housing with slots for ventilation, the containing frame consists of two rings united by horizontal struts at sufficiently close intervals for mechanical strength, the whole being cast in one piece; the stator is mounted in this skeleton frame and the journals are in ring-and-spider brackets very similar to those used on direct-current machines. The new frame gives vastly more effective radiating surface, better ventilation and less weight, without sacrificing any protective features.

C. H. WHEELER CONDENSER & PUMP COMPANY.—The announcement is made that the Barr Pump Company, of Philadelphia, has been taken over by a new company to be known as the C. H. Wheeler Condenser & Pump Company. Mr. C. H. Wheeler, formerly president and manager of the Wheeler Condenser & Engineering Company, is now identified solely with the new company. The personal services of Mr. Wheeler, ample capital, modernly equipped works and an up-to-date engineering staff, place the company in a position of unusual strength on condensing apparatus and pumps of any size and description for all purposes where such machinery is required. The company's principal office is in Philadelphia at Lehigh Avenue and 18th Street, and the New York branch is at 26 Cortlandt Street. Additional branches in Chicago and other large cities will soon be established. The officers of the company are John Pitcairn, president; George Burnham, Jr., who is connected with the Baldwin Locomotive Works of Philadelphia, vice-president; C. H. Wheeler, secretary and general manager; Otto W. Schaum, works manager; W. H. Rometsch, of the Fletcher Works, Philadelphia, treasurer.

CENTRAL STATION NEWS

Readers are cordially invited to contribute to this department items of news relating to plants in their vicinity.

ALABAMA.

TUSKEGEE.—The Council is reported to have decided to construct an electric light plant.

LUVERNE.—The Luverne Electric Light & Water Company has been incorporated with a capital of $10,000, by J. R. Horn, J. M. Cody, R. G. Reddach and others.

LINEVILLE.—The Council has granted to John S. Jamison and associates a franchise for water works and an electric light plant, also telegraph and telephone systems.

ARKANSAS.

EL DORADO.—The new electric light plant, which has been in course of construction for some time, is nearing completion, and it is expected that the town will soon be lighted from that source.

FORREST CITY.—W. M. Partridge is said to have recently acquired a half interest in the plant of the Forrest City Light & Power Company, but none of the details of the transaction have been made public.

CALIFORNIA.

SEBASTOPOL.—The Sebastopol Light, Power & Water Company was recently incorporated with a capital of $25,000, by W. P. English, G. W. Kingsbury and A. B. Swain, of this city.

SAN FRANCISCO.—The new power station of the Mutual Electric Light Company, at the corner of Spear and Folsom Streets, has been running for about six weeks and is giving entire satisfaction.

MODESTO.—It is stated that the Tuolumne Electric Company recently applied for a franchise to erect poles and string wires along the county roads for the transmission of electric current, and bids for said franchise will be received until May 2.

SAN LUIS OBISPO.—The San Luis Obispo Gas & Electric Company is contemplating the construction of an electric light plant, the cost of which is estimated at $30,000. It will be situated near the gas works in this city. Mr. B. F. Thomas is manager of the company.

COLORADO.

GUNNISON.—The citizens voted recently for an issue of bonds to the amount of $100,000, the proceeds to be used in constructing water works and an electric light plant.

STERLING.—The Sterling Public Service Company's plant was burned to the ground on the 20th of April. The building was a total loss. The boilers and engines can be repaired. Generators, switchboard and all supplies are already on hand. The loss is estimated at $8000.

CONNECTICUT.

CHESHIRE.—The Town Council is considering the advisability of establishing a municipal electric light plant.

FLORIDA.

JACKSONVILLE.—The Aultman & Taylor Machinery Company was awarded the contract for supplying a new boiler to the electric light plant here at a cost of $4300.

GEORGIA.

MONROE.—J. B. McCrary, of Senoia, has been selected to prepare plans for an electric light plant. Bonds for the purpose will be issued to the amount of $15,000.

GAINESVILLE.—The North Georgia Electric Company is about to commence the erection of a large dam at Wilson's Shoals, on the Chattahoochee River It will cost approximately $150,000 and 100 men will be employed on the work, which is expected to require a year to complete. About 2500 horse-power will be generated and transmitted to the city for distribution to the various enterprises requiring it. This will be the fifth dam erected by this company. Three have been built on the Chestatee River and one has already been erected on the Chattahoochee River at the Dunlap Shoals. The lower dam on the Chestatee River supplies power to the city, while the two higher up on the river furnish power to Dahlonega plants. The Chattahoochee dam gives current to the street railway system now in operation here. Wilson's Shoals are five miles west of Gainesville and the dam there will be seven miles below the one at Chattahoochee Park. It will be 35 feet high and 600 feet long.

IDAHO.

LEWISTON.—Francis Jenkins, of Moscow, is said to be interested in the construction of a power plant at Elk Creek Falls, near here.

WEISER.—John R. Pierce, Pitts Ellis, W. H. Adams, T. C. Galloway and J. H. Morrison have incorporated the Weiser Electric Light & Power Company, having a capital stock of $50,000. A power plant, estimated to cost $32,000, will be constructed on the Weiser River and pushed to completion as rapidly as possible.

ILLINOIS.

CHICAGO.—A new engine and generator are to be installed in the Chicago Avenue pumping station.

MACKINAW.—The new electric light system is now in operation here and proving very satisfactory.

CHICAGO.—The Western Water, Light & Traction Company has been incorporated with a capital of $10,000.

HENRY.—The plant of the Henry Electric Company, formerly owned by the Messrs. Sterrett, has been sold to J. J. Crickenberger.

WOODHULL.—The plant of the Woodhull Electric Light Company is said to have been destroyed by fire recently, but the extent of the loss is not known.

PARIS.—The electric light and gas plants have been sold to J. N. C. Shumway, of Taylorville, who is said to be the Western agent of a syndicate of Eastern capitalists.

MIDDLETOWN.—Mr. Sturgis, former proprietor of the electric light plant here, recently traded his interest in the same to W. A. Crawford for residential property owned by the latter in Delavan.

CHICAGO.—It is stated that the Chicago Edison Company is about to erect a sub-station at 8284 Market Street. The plans are being prepared by Shepley, Rutan & Coolidge. It will be a two-story building, 40 x 100 feet, built of brick and stone, and will cost $75,000.

MARSEILLES.—The water works and electric light plant, heretofore operated by the Marseilles Land & Water Power Company, are said to have passed under the control of a new corporation, known as the Consolidated Water & Light Company, and having a capital of $100,000. It is proposed to erect a new power house, the old water works station is to be torn down and the flume enlarged. It is also proposed to install an auxiliary steam plant. John M. Nicholson is president of the new concern, and A. E. Cooper, secretary.

INDIANA.

LA PORTE.—Frank R. Northam has been appointed receiver for the Edwards Railway & Electric Light Company.

HOPE.—The contract for the new electric light plant to be erected in this city has been awarded to the Ryan Construction Company, of Indianapolis.

LEBANON.—It is reported that Cropsey & Lamm, of Cincinnati, are preparing plans for an electric and cold-storage plant to be constructed here.

CONNERSVILLE.—The Connersville Gas, Electric & Power Company's plant has been sold to George B. Markle, of Hazleton, Pa., who will expend a considerable sum in improvements.

LIGONIER.—Bids are being considered for lighting the city by electricity for a term of ten years from November, 1905, with forty or more 2000-c.p. enclosed-arc lamps; also for furnishing an incandescent sysem of electric lighting, and a system of commercial arc lights for business houses and residences for the same term of years.

MISHAWAKA.—The plans for the organization of the Indiana & Michigan Electric Company have been consummated and the company has filed articles of incorporation. A plant will be erected on the St. Joseph River, whence power will be distributed throughout Indiana and Michigan for lighting and operating trolley lines and manufacturing plants.

MUNCIE.—The Citizens' Electric Light Company, capitalized at $200,000, and composed largely of Muncie business men, has been organized for the purpose of supplying electric light to Muncie people at a cost of 5 cents a thousand watts instead of 12 cents, which is the charge now made for supplying lights for commercial purposes. William F. Warner is president and C. R. Hathaway, secretary.

INDIAN TERRITORY.

COWETA.—The Coweta Electric Light Company has completed its plant and is wiring the town. Orders have been received for over 200 lights, besides those furnished the municipality.

MUSKOGEE.—The Grand River Power Company has been organized and incorporated, with a capital of $10,000. A 40,000-h.p. plant will be constructed on the Grand River, about eleven miles below here. Current for lighting and power purposes will be furnished to this city, and Wagoner and Fort Gibson are also interested in the project. C. N. Haskell is president and Carl Pursell, secretary, both of this city.

IOWA.

LETTS.—An electric light plant is to be installed in this city by the Reinz Company.

CONRAD.—W. J. Stanton is interested in the construction of an electric light plant here.

SIOUX CITY.—Samuel McRoberts and Edward Tilden have been granted a franchise to establish an electric light plant in this city.

MISSOURI VALLEY.—L. A. Little is said to have succeeded to the entire business of the Missouri Valley Electric Light Company.

WINTERSET.—The Des Moines Heat, Light & Water Company, of Des Moines, is reported to be considering the advisability of putting in a central heating plant and water works at this place, at a cost of $60,000.

KANSAS.

LINDSBORG.—Bids are being considered for the construction of a municipal lighting plant to cost $29,000. George C. Morgan, of Chicago, is the engineer in charge of the work.

ELLSWORTH.—Paul Reaume is said to have purchased a portion of the lot on which is located the Ellsworth Electric Light Company's plant. Reports state that Mr. Reaume will be interested in the construction of a new power house in the near future.

LYONS.—The Lyons Electric & Manufacturing Company will receive bids about May 10 for machinery for an electric light plant, which will cost from $8000 to $10,000. The company has engaged a superintendent and will construct the plant by its own labor. The new concern has been granted a twenty-year franchise.

KINGMAN.—The plans and specifications have been completed for the hydro-electric power station of the Kingman Light & Power Company, a concern recently incorporated with a capital of $25,000. The plant will be operated by means of water power derived from the Minnescah River, and an auxiliary plant will be installed equipped with a gas engine and suction gas producer.

WAVERLY.—The contracts for constructing an electric light plant have been awarded as follows: For engine, boiler, pipe and fittings, English Iron Works, Kansas City, Mo.; generator exciter and switchboard, Hodge-Walsh Electrical Company, Kansas City; heater, trap separators, feed pump, etc., Kansas City Engineering Company, and lamp and pole line equipment, to the B-R Electric Company, of Kansas City.

KENTUCKY.

LAWRENCEBURG.—Bids will probably be received shortly for the proposed electric light plant to cost $12,000. Address W. E. Dowling, of the Commercial Club.

CARLISLE.—A company has been organized here, with C. C. Cole as president; M. V. Bostain, vice-president; George A. Straus, secretary, and John N. Riss, treasurer. Active construction work has been begun on a $15,000 electric light plant, and it is hoped to have it in operation about the first of June.

DANVILLE.—The Danville Light, Power & Traction Company has filed articles of incorporation. The following are the officers: President, Charles C. Fox; vice-president, Walter T. Scott; secretary, treasurer and general manager, Arnold Honegger. Work will begin at once on an up-to-date electric light plant.

LOUISIANA.

HOMER.—Charles H. Levy, consulting engineer, of Shreveport, writes that it is proposed to construct water works and an electric light plant here at a cost of $20,000.

LAKE CHARLES.—Bids are being considered by the Council for furnishing the city with electric lights; also for the sale of the franchise for the use of the streets for electric lighting.

AMITE CITY.—H. C. Hull, of this city, and Hyman C. Reed, of New Orleans, are erecting an electric light and power plant here. The plant will also furnish lights to Roseland and Independence.

MAINE.

BRADLEY.—Local press reports state that Fred W. Ayer, of Bangor, and associates, will construct an electric plant for the generation and distribution of electricity for power purposes in Bradley.

PORTLAND.—The Cascade Light & Power Company has been incorporated with a capital of $100,000 to manufacture and distribute gas and electricity. C. C. Hight, of Boston, is president, and L. L. Hight, of this city, is secretary.

BANGOR.—Report is received of the consolidation of the Oldtown Electric Light Company, the Bangor, Orono & Oldtown Railway Company, the Public Works Company, and the Bangor, Hampden & Winterport Railway Company, under the name of the Bangor Railway & Electric Company. The company is capitalized at $1,000,000.

BANGOR.—Maine people and especially those on the northeastern border will be interested to learn that the Grand Falls Power Company has been incorporated at Ottawa, Ont., with a capital stock of $200,000. The incorporators are: Sir William C. Van Horne, of Montreal; U. S. Senator Redfield Proctor, of Proctor, Vt.; Richard B. Angus, of Montreal; Hugh Havlock McLean, of St. John, N. B.; Frank C. Partridge, of Proctor, Vt.; Frank Ray Kimbley, of New York, and Ernest Alexander of Montreal. The company's plans include the construction of a canal and hydraulic raceway, dams, conduits, buildings, wharves, reservoirs, flumes, railways and all other improvements necessary for the successful development of power at Grand Falls, N. B.

MARYLAND.

MARYLAND.—Plans have been completed by the Baltimore County Water & Electric Company for a power house to be erected at Herring Run. S. W. Cooper, Highlandtown, is chief engineer and superintendent.

MASSACHUSETTS.

MANSFIELD.—At a town meeting held recently it was voted to extend the electric lighting system to West Mansfield station.

HOLYOKE.—The Holyoke Water Power Company is completing plans for utilizing the surplus water of Connecticut River; it is proposed to expend about $60,000.

MICHIGAN.

L'ANSE.—It is stated that $10,000 bonds will be issued for the construction of an electric light plant.

JACKSON.—The Commonwealth Power Company has let the contract for a $100,000 steam power plant to be constructed by them here.

DETROIT.—The House is reported to have passed a bill granting permission to the city to issue $150,000 bonds for lighting improvements.

BARAGA.—The Legislature has passed a bill allowing this village to issue $40,000 bonds for the construction of an electric light plant and water works.

MENDON.—The citizens have voted to issue bonds to the amount of $15,000, the proceeds of which will be used to establish water works and an electric light plant.

MUSKEGON.—The ordinance granting to the Morton B. Wheeler Company a franchise to furnish electric light and power within the limits of Muskegon has been passed by the Council.

MENOMINEE.—Reports state that Holmes & Son, of this city, are perfecting plans for the construction of a dam and canal at Grand Rapids on the Menominee River, which will furnish electric power to the amount of from 4000 to 10,000 horsepower. The company owns the land on both sides of the river at Grand Rapids and has recently secured a charter for the establishment of a power plant at that point.

PENTWATER.—The Oceana Electric Company has been succeeded by the Oceana Electric Light & Power Company, Inc., with B. C. Lindley, who was manager of the former company, as president. The company is now in the market for bids for the construction of a hydro-electric plant in this vicinity, the equipment to include two direct-connected units of 400 and 300 horse-power capacity and about 38 miles of 25,000-volt lines. It is desired that the work proceed as far as possible before winter.

MINNESOTA.

DULUTH.—Bonds are being sold to the amount of $140,000 for water works and a lighting plant.

TORAH.—The Torah Telephone & Improvement Company has been incorporated to construct water works, an electric light or gas plant and a telephone exchange.

MINNEAPOLIS.—Notice is received of the incorporation of the International Lighting Company, with a capital of $2000, by C. W. Jenne, J. W. Furber and others.

WINONA.—An ordinance authorizing the Minnesota Light & Power Company to erect and maintain poles and string wires in the streets of the village has been passed.

WALKER.—Bids are being considered by the Village Council for the removal and extension of the electric light and water plant, for which $4000 bonds were recently issued.

FAIRMONT.—The citizens voted April 4 to issue $18,000 bonds for improving the electric light plant and installing water works, and $10,000 for establishing a sewerage system.

SANBORN.—It was voted at a recent election, held for the purpose of deciding the matter, to issue bonds to the amount of $6000 for the installation of a village lighting plant.

MINNEAPOLIS.—Reports state that the Minneapolis General Electric Company is about to let contracts for work in connection with utilizing the water power of St. Croix River, at St. Croix Falls, between the villages of St. Croix Falls and Taylor's Falls, this State.

FERGUS FALLS.—The City Council and Electric Light Commission have decided to rebuild the dam which supplies the city's electric light plant with power. It is proposed to build a cement dam if the bottom of the river is found to be suitable, and the new structure will be several feet higher than the old one as more power is needed. Its cost will be over $40,000.

MINNEAPOLIS.—Joseph L. Kuchle is reported to have filed with the city a bond and acceptance by the Minnesota Power & Trolley Company, of the ordinance granting the right to use the city streets for conduits and poles, to convey electric energy to the city, and to supply electric light and power to consumers. The company agrees to begin actual work on construction and expend at least $200,000 within one year.

MISSISSIPPI.

LIBERTY.—The Board of Aldermen has granted W. M. White a franchise for water works and an electric light plant.

ROSEDALE.—A committee has been appointed to procure estimates on the cost of an electric light plant to be operated in connection with the municipal water works.

GULFPORT.—The City Council has passed an ordinance granting Capt. J. T. Jones and associates a fifty-year franchise for an electric railway, light and power plant.

MERIDIAN.—Mayor J. H. Rives will receive bids May 1 for furnishing 200 1200-c.p. arc lights for a period of five years from May 1, 1906; 200 or more alternating-current enclosed-arc lamps, 66 amperes each, potential of not less than 72 volts between the terminals of each arc lamp and an apparent wattage of 475 watts for each lamp; lamps in the business section to burn all night, others to run on moonlight schedule. A franchise will be granted to the successful bidder.

MISSOURI.

TROY.—The City Council has purchased a site for the municipal electric light plant.

MADISON.—The citizens voted April 4 to issue $5000 bonds for an electric light plant.

LAWSON.—Michael Maloney, of Chillicothe, is said to be negotiating for the purchase of the electric light plant of this place.

MARSHALL.—A. H. Bickmore & Co., of New York City, have purchased the gas and electric light plants of this place. The two plants will be consolidated and extensively improved.

NEBRASKA.

LINCOLN.—The poles have arrived for the municipal lighting plant and construction work will be pushed rapidly.

ARLINGTON.—The Arlington Electric Light Company has been incorporated by G. F. Upland and others. The company's capital is placed at $10,000.

DODGE.—It is proposed to construct water works and an electric light plant here at a cost of $10,000. Bonds for the purpose will be issued shortly. No engineer for the work has been selected as yet.

NEW HAMPSHIRE.

LACONIA.—Reports are to the effect that Massachusetts and Rhode Island capitalists have purchased the plant of the Laconia Electric Light Company and will enlarge it. The latter company was recently awarded the contract for lighting the city for a period of ten years for about $7000.

NEW JERSEY.

DUNELLEN.—Edwin W. Hine, representing the Public Service Corporation, has petitioned the Borough Council for a franchise to lay pipe through the town.

LAMBERTVILLE.—The Lambertville Heat, Light & Power Company has been awarded the contract to wire the Centenary M. E. Church for electric lighting.

WOODBURY.—Articles of incorporation for the Gloucester County Electric Company have been filed by Enos R. Artman and Daniel Eady. The company is capitalized at $50,000 and will generate and distribute electricity.

ATLANTIC CITY.—The Atlantic City Suburban Electric Company is reported incorporated with a capital of $100,000 to furnish heat, light and power. It will petition for a franchise in Pleasantville. Among the incorporators are Louis E. Kuehale, Harry E. Woodman and John C. Reed.

NEW MEXICO.

ROSWELL.—The Citizens' Light, Heat & Power Company has been incorporated with a capital of $100,000. J. A. Buckley, of Kingfisher, Okla. Ter., is one of the incorporators.

NEW YORK.

SPRINGVILLE.—Bonds are to be sold to the amount of $12,000 for the erection of an electric lighting plant.

TONAWANDA.—The Niagara, Lockport & Ontario Power Company has petitioned the Council for a franchise.

POTSDAM.—The citizens have voted to issue $40,000 bonds for the installation of a municipal electric light plant.

CLINTON.—The Governor has signed the bill authorizing the city to issue $7000 bonds for an electric light plant.

WHEATFIELD.—The Niagara, Lockport & Ontario Power Company has petitioned for a franchise in Wheatfield.

SALAMANCA.—C. F. Buckmaster, City Clerk, writes that the citizens have voted to purchase the electric light plant and water works.

NEW YORK CITY.—The Williamsburg Power Company, with a capital of $150,000, has been incorporated by E. P. Foster, James Foster and W. H. Robinson.

LIVONIA.—Articles of incorporation have been filed for the Livonia Light & Heat Company by E. C. Blake and F. A. Wicker. The company is capitalized at $12,000.

PENDLETON.—The Town Council has granted the Niagara, Lockport & Ontario Power Company a franchise to construct a power canal and transmission line through the town.

ROCHESTER.—Contracts have been made by the Rochester Railway & Light Company for new buildings, improvements and additions, involving an outlay of more than a million dollars this year.

NEW YORK CITY.—The incorporation is reported of the Morgan & Wyman Electric Light & Power Company with a capital stock of $6000. C. B. and Cora Morgan, of Armenia, N. Y., and C. S. Wyman, of Dover Plain, are the incorporators.

NEW YORK CITY.—The Manticaw Light, Heat & Power Company has filed articles of incorporation, stating its capital stock to be $50,000. Among those interested in the project are Michael F. Burns, of Brooklyn, and Solomon M. Shatzkin, of Passaic.

MONROE.—Z. Paddleford and Luther Terwilliger are said to be among the incorporators of a company organized under the title of the Orange & Rockland Electric Company. The company is capitalized at $50,000, and the directors hope to have the plant in operation early in July. It will be located in Monroe and current will be furnished for lighting this city, Chester and other surrounding villages.

GLENS FALLS.—Eugene L. Ashley, president of the Hudson River Water Power Company, has announced that he has contracted to furnish the New York Central 25,000 electrical horse-power yearly for twenty-five years. The minimum charge will be $125,000 per year, and the contract may cost the Central as high as a half million a year. Power will be delivered in July from Spier Falls and Schoharie Falls, together with a current from a temporary steam plant to be erected at Utica. The energy will be used in the development of the various trolley interests which the Central railroad is fast taking up. The Power Company will now hasten its plants for utilizing the waters of the Schoharie River. One power plant has already been built and four more will follow. This work will be completed in about two years and until that time the Utica steam plant will be utilized to fulfill the Central contra

NORTH CAROLINA.

SPENCER.—The Board of Aldermen has awarded to the Salisbury & Spencer Street Railway Company the contract to install a system of electric lights in Spencer, the system to be in operation by May 15.

NORTH DAKOTA.

JAMESTOWN.—The Jamestown electric light plant is to be enlarged and improved, reports state.

GRAND FORKS.—The citizens voted April 3 to issue $30,000 bonds for the construction of a municipal electric light plant.

OHIO.

ARCANUM.—It has been voted by the citizens to issue $38,000 electric light and water bonds.

MADISON.—The question of establishing an electric light plant is said to be under consideration here.

LOCKLAND.—The citizens have voted to issue $27,000 bonds for extending the water mains and enlarging the electric light plant.

URBANA.—J. C. Powers, Paul C. Martin, and others, have filed articles of incorporation for the Urbana Light Company, with a capital of $100,000.

BELPRE.—There is reported to be a movement on foot here looking to the construction of a water works system and an electric light plant.

CLEVELAND.—The Cleveland Electric Illuminating Company has been granted a permit for the erection of a lighting station at 1845 Doan Street, to cost $12,000.

LINTON.—The Linton Light, Power & Fuel Company was recently incorporated by F. C. Roundy, J. W. Swatek and John McMadden, the company being capitalized at $125,000.

SPRINGFIELD.—Local reports state that if the E. S. Kelly Home Heating, Light & Power Company secures a blanket franchise, it will expend $50,000 this year in improvements.

GALION.—The Crawford Gas & Electric Company has filed articles of incorporation, stating its capital stock to be $150,000. Among these interested in the project are S. N. Blake and P. P. Jenks.

CLEVELAND.—The People's Electric Lighting & Power Company, having a capital of $10,000, has filed articles of incorporation, naming among others H. T. Emerson and William Brodie as incorporators.

MAUMEE.—The Public Service Company has been incorporated for the purpose of conducting electric lighting and heating plants. The company has a capital of $50,000, and among the incorporators are George McGovern, James H. Ragan and Thomas H. Harper.

DAYTON.—The Montgomery County Electric Company, which was recently incorporated with a capital of $100,000, is said to have been consolidated with the Dayton Electric Light Company. The new concern will be known as the Dayton

Lighting Company and is capitalized at $2,500,000. About $1,000,000 will be spent in new equipment, it is said, $600,000 worth of new machinery having already been ordered. The officers of the combined company are reported as follows: President, J. E. Lowes; vice-president, H. E. Runkle; secretary and assistant treasurer, R. E. DeWeese.

OREGON.

SALEM.—H. D. Wagnon, an attorney of Portland, is said to be interested in the construction of an electric light and power plant at this place.

OREGON CITY.—The Portland General Electric Company has petitioned the County Commissioners for a franchise over the county roads between Oregon City and Aurora. It will also petition for a franchise in Marion County for a transmission line between Aurora and Salem.

PENNSYLVANIA.

ALLENTOWN.—A well-organized movement is on foot here looking to the establishment of a new electric light company.

WELLSBORO.—It is stated that the Wellsboro Electric Light Company will erect a power plant here this summer. W. S. Culver is superintendent.

ALTOONA.—The Citizens' Electric Light, Heat & Power Company, it is said, will build a number of extensions to its lines during the coming summer.

DEBRING.—P. J. Edwards, proprietor of the electric light plant here, has sold the plant and property to Pittsburg capitalists in consideration of $10,000.

PHILADELPHIA.—The Michigan-Lake Superior Power Company is said to have in contemplation plans for improvements which will require the expenditure of about $800,000.

DOYLESTOWN.—The electric light and power plant of the Lehigh Power Company, located below Raubsville, is said to have been purchased by B. F. Fackenthal and Lee S. Clymer.

WERNERSVILLE.—The Wernersville Light, Heat & Power Company has been granted a charter to supply light to the Borough. The company has a capital of $5000, and among the stockholders are George W. Wertz, Robert W. Wertz and David Froelich.

RHODE ISLAND.

PROVIDENCE.—The Woonsocket Electric, Machine & Power Company has signed contracts whereby the company agrees to furnish electricity for twenty years to the Woonsocket Street Railway Company, the Columbian Street Railway Company, and the Burrillville Street Railway Company.

PROVIDENCE.—Walter I. Barnes, who for the past six years has been general superintendent of the Narragansett Electric Lighting Company, has taken the position of assistant general manager, recently made vacant by the resignation of Arthur B. Lisle. Mr. Barnes became identified with the Narragansett Electric Lighting Company thirteen years ago and was in the office of the treasurer for three years. Ten years ago he was transferred to the station on Elm Street, where he had charge of the generation and distribution of current and the purchase of supplies. It is understood that the company will expend in the near future about $200,000 in underground construction and the rewiring of houses on the East Side.

SOUTH CAROLINA.

GREENWOOD.—New electrical equipment is to be installed in the city water and electric light plant, it is said.

BAMBERG.—The citizens voted April 3 to grant to D. J. Howell and associates a franchise for water works and an electric light plant.

FLORENCE.—The Florence Electric Light & Power Company is arranging to furnish lights to Timmonsville. The company will also do commercial lighting in that town.

GREENVILLE.—A charter has been granted to the Saluda River Power Company with a capital of $300,000. It is proposed to develop power five miles from this city to supply textile and industrial enterprises. Lewis W. Parker, A. G. Furman and H. J. Haynesworth are the incorporators.

SOUTH DAKOTA.

MITCHELL.—The plant of the Electric Light Company has been sold to the Mitchell Gas Company for a consideration of $20,000.

GRAND FORKS.—The proposition to bond the city for $30,000, which has been under discussion here for some time, was decided at a recent election in favor of issuing the bonds.

TENNESSEE.

COOKEVILLE.—An electric light plant is to be installed here at a cost of $25,000.

DICKSON.—The citizens have voted to issue $6000 bonds for an electric light plant.

MEMPHIS.—The House is reported to have passed a bill providing for the municipal ownership of the lighting plant.

COLLIERVILLE.—Kirkpatrick & Johnson, of Jackson, Miss., have been selected to prepare plans for an electric light plant for this town.

DRESDEN.—The citizens have voted to issue $10,000 bonds for the establishment of a water works system and an electric light plant.

ATHENS.—It is reported that the Athens Light & Power Company has sold its plant to Long Brothers, who will make considerable additions to the equipment.

SHELBYVILLE.—There is reported to be a movement here looking to the purchase of the present water works and electric light plant by the town, or Council may decide to construct new plants.

TEXAS.

FORT WORTH.—The Bound Electric Company has succeeded to the business of the Broiles Electric Company.

SAN AUGUSTINE.—A. A. Sheffield is said to be interested in the construction of an electric light plant for this place.

FORT WORTH.—George W. Armstrong has secured a permit for the erection of a power house at a cost of $4,000.

BROWNSVILLE.—The People's Ice & Light Company has completed the ice plant and will begin the electric light plant at once.

SAN ANGELO.—U. G. Taylor, of this city, is reported to be interested in the construction of an electric light plant at Angelo Heights.

BARTLETT.—R. S. Decker has secured a franchise for the construction of an electric light plant and ground has been broken for the building.

FORT WORTH.—The Fort Worth Light & Power Company will soon begin the erection of a two-story brick store-room building, at a cost of $12,000.

McKINNEY.—The contract for constructing the municipal electric light plant has been let to the Hunter Electric Light Supply Company, of Dallas, for $6500.

BRADY.—The Brady Water & Light Company has been incorporated with a capital stock of $20,000. Among the incorporators are G. R. White and C. C. Baumgardner.

UTAH.

LOGAN.—Shepherd, Monson & Schaub have decided to install a power plant of 500 horse-power in Cache County.

FAIRVIEW.—The Fairview Electric Light & Power Company has filed articles of incorporation with the Secretary of State. The company has a capital of $15,000. Peter Olsen is president, and Peter Sundwale, secretary and treasurer.

VIRGINIA.

CAPE CHARLES.—I. J. Burbage, Town Clerk, writes that as no bids were received on April 3 for the electric light franchise the time for receiving them was extended sixty days.

LURAY.—The plant of the Luray Electric Company has been completed, and the company is prepared to supply 60-cycle, 110-volt alternating current for operating fans and motors.

WASHINGTON.

RITZVILLE.—C. O. Green has sold his electric light plant to N. H. and O. H. Green.

BALLARD.—The Ballard Electric Company has secured a new franchise and will make extensions to its plant.

HARRINGTON.—William Brodie and James Shaw, of Ritzville, have made application for a franchise for an electric light plant in this city.

SEATTLE.—The South Bend Electric Company, of which C. H. Kiehl is purchasing agent, is said to be in the market for an auxiliary steam plant.

KELSO.—The Kelso Water & Light Company has completed its water works and has secured a lighting franchise. It is proposed to construct an electric light plant at a cost of $10,000, but the company is not yet prepared to consider bids.

TACOMA.—The City Council has under consideration an offer from the Equitable Finance Company, of Portland, Ore., to construct a hydraulic power plant on Nisqually River, twenty-five miles from the city, to develop 5000 horse-power, the city to take the plant when completed.

ABERDEEN.—Plans are being drawn for extensive additions to the plant of the Grays Harbor Electric Lighting Company in East Aberdeen. The new building will be 45 x 96 feet and 22 feet high, with space for a 400-kw. turbine, the necessary boilers and other new machinery which the company has ordered.

WEST VIRGINIA.

KINGWOOD.—It is proposed to purchase a new dynamo for the electric light plant and install new wiring throughout the town. J. H. Kramer is chief electrician.

WHEELING.—The Dillonvale Heat, Light, Power & Water Company has been organized and has already purchased a site for the plant, which will be located on Piney Creek. The work of setting the poles and stringing the wires is well under way.

NORFOLK.—The Elkhorn Light & Power Company has been incorporated with a capital of $100,000 to own and operate power plants, to generate electricity for heating, lighting and power purposes; also to construct telephone and telegraph lines. J. J. Tierney and L. H. Clark are among the incorporators.

SISTERVILLE.—The Sisterville Light & Power Company has recently changed its circuits from a 133-cycle to a 60-cycle system. The company reports marked success in thawing out frozen water pipes electrically this past winter. Within a few weeks, over sixty services were operated on. As several of these were more than 100 feet in length and entirely underground, a considerable saving to the owner over the old method has been effected.

MARTINSBURG.—Capitalists of Washington and Baltimore are organizing a stock company for the purpose of purchasing the old pulp mills and water power at Harpers Ferry, where it is intended to erect a large electric light plant. It is said that $150,000 has been subscribed and that the venture is already assured. It is expected to make this plant a central point for supplying electric light to several cities and towns in the valley, and negotiations are under way with Winchester, Brunswick, Harper's Ferry, Charlestown, Hagerstown, Williamsport and other places.

WISCONSIN.

STOUGHTON.—The citizens voted April 3 to issue $25,000 bonds for a municipal lighting plant.

OSHKOSH.—The lighting contract for the city has been awarded to the Oshkosh Electric Light & Power Company.

JANESVILLE.—Bids are being considered for lighting the city with electricity for a period of five years from the 10th of July.

KENOSHA.—Mayor Gorman is reported to have begun a movement in this city to secure a municipal lighting plant. The present contract expires in two years.

MEDFORD.—Robert Mackenzie has resigned as manager of the plant of the Medford Light & Heat Company, Inc. and will be succeeded by William Johnson.

CADOTT.—The village of Boyd has granted a franchise to the Cadott Light & Power Company. The company will extend its line to that village in the near future.

BEAVER DAM.—The Beaver Dam Illuminating Company expects to install in its plant this summer a 100-kw., 60-cycle, alternating-current, direct-connected generating unit.

MILWAUKEE.—The Milwaukee Heat Light & Traction Company has increased its capital from $500,000 to $1,000,000. Most of the increase will be used for improvements.

MINOCQUA.—John Woodloch, of Merrill, owner of the electric light plant here, contemplates rebuilding the plant this coming summer, to include new dam, new water wheels, new dynamo and a new line five miles in length.

PLATTEVILLE.—The Platteville Electric Light & Power Company, recently organized, has filed an amendment to its articles of incorporation increasing its capital stock from $20,000 to $50,000. M. S. Sickle is president and J. H. Evans, secretary.

BERLIN.—The Berlin Lighting, Heating & Power Company has secured the contract for lighting the city for the next ten years. A 200-kw. generator and a 250- h.p. engine will probably be installed in the company's plant during the coming summer.

ONALASKA.—The City Council is considering the matter of electric lights. L. Stinson, of West Salem, has applied for a franchise, and if granted, he will build a plant on La Crosse River. The Wisconsin Light & Power Company, of La Crosse, has also made application for a franchise.

KAUKAUNA.—After May 1 the Kaukauna Electric Light Company will run both a day and night circuit and the city lighting will be done upon an all-night, every-night schedule. The water wheel capacity of the plant will also be increased and a direct-current power circuit, supplying 100 horse-power, has already been added.

MADISON.—The incorporation of the Wisconsin River Traction & Power Company and the Mathie Brothers Lumber Company is the beginning, it is said, of a large interurban-railway. water-power and paper-mill system. The former corporation, headed by Neal Brown, is capitalized at $30,000, and the latter at $90,000. Trappe City water power will be developed.

LA CROSSE.—Mr. Charles H. Williams, who has been with the Madison Gas & Electric Company, Madison, and who is president of the Northwestern Electrical Association, has resigned his position with the Gas & Electric Company to accept one as general manager of the Wisconsin Light & Power Company, of this place. The other officers of the company, which is a recent organization, are as follows: President, Henry A. Salzer; vice-president, J. J. Hogan; treasurer, G. Van Steenwyk; secretary, J. George Schweizer.

WYOMING.

CODY.—George T. Beck is pushing work very rapidly on the electric light plant, for which he was recently granted a franchise by the Town Council.

CANADA.

BRANDON, MAN.—Plans and specifications are being prepared for an electric light plant to light the streets and public buildings.

WESTMOUNT, QUE.—The Council has under consideration the construction of a municipal water works and an electric light plant.

QUEBEC, QUE.—The Quebec-Jacques-Cartier Electric Company is arranging to construct an additional dam in order to increase its power facilities.

SYDNEY, N. S.—The Council has decided to issue bonds to the amount of $60,000 for the purpose of constructing and equipping an electric light plant.

DUNCANS, B. C.—A by-law is to be submitted to the taxpayers of the city, empowering a company to install an electric light system during the coming summer.

ROSSLAND, B. C.—The West Kootenay Power & Light Company, of this city, has commenced an elaborate scheme of development of the upper falls of the Kootenay River at Bonnington.

CHARLOTTETOWN, P. E. I.—W. W. Clark, City Clerk, writes that it is proposed to apply to the Legislature for permission to construct an electric light plant at a probable cost of $75,000.

NORTH BAY, ONT.—The North Bay Light, Heat & Power Company has been organized recently, with a capital of $50,000, to generate and distribute electricity and gas for lighting and power purposes.

NIAGARA FALLS, ONT.—A bill has passed the Dominion Parliament granting permission to the Niagara & Welland Power Company to construct a power and ship canal from Welland Canal to Lake Ontario.

NEW GLASGOW, N. S.—A number of capitalists of Philadelphia are organizing a company for the purchase of the Edgerton Tramways Company, Ltd., and the New Glasgow Electric Light Company, both of this city.

INDIAN HEAD, N. W. TER.—The Council has been investigating the cost of constructing water works, a sewerage system and an electric light plant. John Galt, of Toronto, has submitted an estimate of $135,000 for the work.

QUEBEC, QUE.—The Quebec-Jacques Cartier & Power Company is considering plans for the construction of a dam on Montmorency River at the foot of the Natural Steps; it will be 90 feet high, 12 feet wide at the top and 65 feet wide at the bottom.

EBURNE, B. C.—Dalton & Everleigh are preparing plans for the new sub-station to be erected at this place at a cost of $40,000. The electrical equipment will have a capacity of 1000 horse-power. Nearly fifty miles of copper wire have been ordered at a cost of $45,000.

VICTORIA, B. C.—The electric light committee has presented a report to the City Council recommending the purchase of the following machinery: One new 230-light dynamo; one exciter; a new switchboard; three 50-light transformers; one belt, pulley and accessories, and new arc lights to the value of $4500.

TORONTO, ONT.—The Ontario & Minnesota Power Company has been incorporated, with a capital of $3,000,000, by W. E. Backus, of Minneapolis, Minn.; R. A. Grant, an attorney, of Toronto, and others, to develop water and other power for the transmission of electricity. The principal office is to be at Toronto.

GRAND FALLS, B. C.—The Grand Falls Power Company has been incorporated with a capital of $200,000, by Sir William C. Van Horne, of Montreal; Hugh Havelock MacLean, St. John, N. B.; Frank C. Partridge, Proctor, Vt., and others, to construct, equip, maintain and operate a canal and hydraulic raceway at Grand Falls.

CALGARY, N. W. TER.—The contracts for constructing an electric light plant for the city have been awarded as follows: Two Babcock & Wilcox 250-h.p. boilers with feed pumps and set up complete, Babcock & Wilcox, for $13,150; for a 350-h.p. compound Corliss engine, with condenser, heater, etc., to the Robb Engineering Company. for $9,574.

TORONTO, ONT.—At the annual meeting of the Toronto Electric Light Company the report of the president showed that the income of the company for the past year was $752,315, and the expenses, including interest on debentures, amounted to $450,273, which left a balance of profit of $302,041, out of which were paid four quarterly dividends at the rate of 7 per cent per annum, amounting to $187,965, leaving a balance of $114,076 to be carried forward to the credit of profit and loss. A reserve account has been created, and $300,000 has been transferred from profit and loss for that purpose. Considerable expenditures have been made looking toward the utilization of power from Niagara Falls, including underground conduits and cables.

MEXICO.

ABOL GRANDE.—The Agencia Commercial y Maritima will install an electric light plant here.

TEMASCALTEPEC.—Francisco Segura & Bro. will install an electric light and power plant at this place.

NUEVO LAREDO.—A company has been formed by Octaviano Gonzalez and associates, with a capital of $30,000, to construct an electric light plant here.

LAMPAZOS.—Arthur E. Banks, of Monterey, will install an electric light and power plant in this city. The plant will have an initial capacity of about 1000 incandescent lights, besides a number of arc lights.

XICOTLACOTLA.—Samson Lang has obtained a concession from the government authorizing him to utilize water from Amacuzac River, in the district of Jojutla, State of Morelos. The quantity granted is up to 78,000 liters per second, to be used for motive power.

CITY OF MEXICO.—The San Lorenzo waterfall, situated near Parral, has been purchased by James Roberts of the city of Durango. It is the intention of Mr. Roberts to establish a large electric power-transmission plant at the falls and to furnish power for mines and other industries. He paid $400,000 for the waterfall.

TLAXCALA.—The Aldermen of this city and the Governor of the State, Colonel Cahuantzi, are constructing a hydraulic plant near here which will develop 3000 horse-power. The power will be applied to various industries to be established near this city. The work was commenced about two years ago and over $50,000 has been already expended on it.

CITY OF MEXICO.—Col. W. C. Greene, the copper magnate of New York and Cananea, Mexico, is pushing forward his plans for building a large electric power plant on the Aros River, near the new town of Dedrick, which he is establishing. The line will be about 150 miles long, it is said. It is estimated that 30,000 horse-power can be developed by the water of the river at the point where the generating plant is to be located.

ZAPOTLAN.—It is announced that the steam-power electric lighting plant of the city of Zapotlan, which now furnishes 1500 electric lights and is capitalized at $96,000, has been acquired by a company composed of Rafael Arias, D. Villanueva and Ugarte & Fuentes, electrical engineers of the city of Guadalajara. The new owners will install a large plant to generate electrical energy by means of water power. The plant will be located at the Piedras Negras falls of the Covianas River, 16 miles from Zapotlan.

MONTEREY.—The Monterey Electric & Gas Company has been incorporated under the Canadian laws, with a capital of $3,000,000, for the purpose of conducting extensive electric lighting and traction business in and around Monterey, the capital of Nuevo Leon, Mexico, and one of the most important manufacturing cities in the southern republic. Interests largely identified with the powerful Canadian syndicate, which is primarily concerned in the Sao Paulo (Brazil) Tramway Light & Power Company, the Havana (Cuba) Electric Railway Company, the West India Electric Company, Limited, of Kingston, Jamaica; the Trinidad Electric Company, of Port au Spain, Trinidad, British West Indies; the Mexican Light & Power Company, Limited, and the Rio Janeiro (Brazil) Tramway Light & Power Company, Limited, are behind the new enterprise. The incorporators of the company are William Mackenzie, who is president of the Toronto Railway Company, the Sao Paulo Tramway Light & Power Company, and Mr. William Laidlaw, Z. A. Lash and A. W. Mack, all of Toronto, and Mr. H. S. Holt, of Montreal. Negotiations are now being conducted with the Monterey Light & Power Company, Limited, regarding the taking over of that concern's property by the Canadian company. The Monterey Light & Power Company operates an extensive lighting system in Monterey. The company is controlled by J. G. White & Company and H. W. Halsey & Company, of New York, Mr. P. G. Gossler, vice-president of J. G. White & Company, being president of the company, while Mr. H. R. Tobey, of the Halsey banking house, acts as secretary and treasurer. The chief engineer of the company is Mr Emilio Dysterud. The capital of the company is $500,000. The Canadian company has already contracted for the purchase of the existing horse car lines in Monterey, and what is known as the Mackin & Dillon concession. originally granted to the American contracting concern of that name. The purchase price is $450,000 gold. Thirty miles of electric road will be built in the first instance and construction will begin immediately, it is said. Mr Keating, of Toronto, will have charge of the work.

American Electrician.

Vol. XVII. New York, June, 1905. No. 6.

ELECTRIC TRANSMISSION AND DISTRIBUTION IN NEW ENGLAND

STATIONS OF THE CONNECTICUT RAILWAY & LIGHTING COMPANY AT WATERBURY, CONNECTICUT.

The distances over which water power is electrically transmitted in New England are, as a rule, moderate. When compared with the transmission lines of California they become quite insignificant so far as distances are concerned, and unlike these notable systems, the water power stations of New England have to deal with rather low heads of water.

The hydroelectric station of the New Milford Power Company at Bulls Bridge on the Housatonic River in the town of Kent, Conn., has the distinction of being the largest electric generating station using water power in New England. It possesses the largest head of water, the highest transmission voltage and the longest transmission line of any of the many hydroelectric stations in New England, while in point of capacity it exceeds any of the famous water power stations of California, save that at Electra and Colgate.

Bulls Bridge is the site of a highway crossing over the Housatonic River, and is in that part of the valley where the river has a continuous rapid descent with steep, rocky hills close on either side. Near the bridge the valley narrows and the river has cut its way down into solid rock. Below the bridge the river makes a turn of nearly 90°, and then, after flowing nearly straight for about a mile, takes another turn that brings its general direction back to within a small angle of its former course. At a short distance above the bridge, a dam has been built across the river, and a canal starting from one end of the dam skirts the hillside for a distance of about two miles and then terminates in a forebay, where the water stands 110 feet above the surface of the river below the second bend just mentioned. From this forebay a steel pipe carries the water down the steep hillside to the power-house on the river bank. This type of water-power development, comprising a rather long canal, a moderate volume of water and a gradual fall in a river concentrated at a single point, so as to give a head of one to several hundred feet, is quite common in California, but has seldom been attempted in New England.

bay is 13 feet in diameter, and another pipe 8 feet in diameter will subsequently be erected. This 13-ft. pipe after reaching the power-house runs along outside of its river front, and connects with seven smaller pipes that pass through the wall to the water-wheels inside. At the end of this horizontal section of the main pipe, which shrinks in diameter as pipes from the wheels are taken off, it turns into a vertical position and extends to an elevation equal to that of the crest of the main dam. The stand pipe thus formed acts to relieve any undue pressure such as might be caused by the hydraulic ram action following the shutting down of some water-wheels too quickly.

The power house is built entirely of concrete and steel, the foundation being carried to solid rock. The station is formed into one main building 115 feet long by 48 feet wide with an annex in the rear and at the center 44 feet by 48 feet. In the main building are placed the wheel cases, hydraulic valves, governors, generators and exciters; while in the annex forming a part of the main building are found the switchboard, oil switches and electrical connections. In the rear of the annex and separated by a concrete partition wall a space 18 feet by 48 feet is devoted to transformers and lightning arresters.

FIG. 5.—MOTOR-DRIVEN HIGH-TENSION OIL SWITCHES.

Iron Works Company, of Dayton, Ohio. They are 31 inches in diameter and are placed tandem, being direct-connected to the generators and governed by Lombard water-wheel governors. Each pair of wheels has a capacity of 1750 horse-power, making a total for the six units installed of 10,500 horse-power. The three-phase generators have a capacity of 1000 kilowatts each and furnish current at 60 cycles and 1150 volts. They possess a momentary overload capacity of 50 per cent and a guaranteed overload capacity for several hours of 25 per cent. The voltage is stepped up in six oil-cooled transformers in banks of three to 33,500 volts for transmission.

The energy from this water power plant is used on the extensive system of the Connecticut Railway & Lighting Company in Waterbury, New Britain and Cheshire. Two sub-stations are located in Waterbury from which electricity is supplied to all of the street railway lines, as well as to power

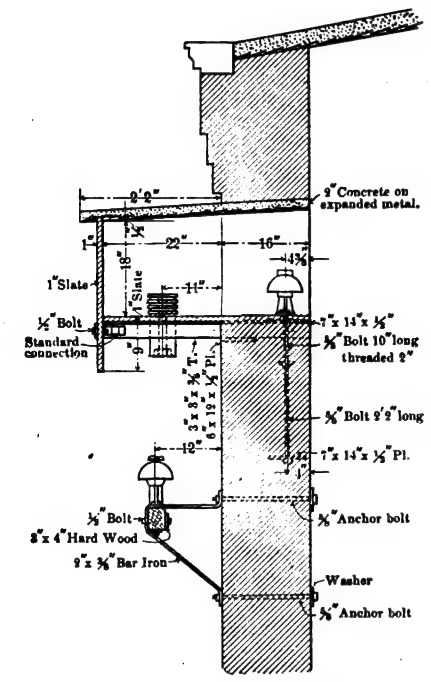

FIG. 6.—DETAIL OF OUTGOING HIGH-TENSION LINE ANCHORAGE.

and lighting circuits. The sub-station in New Britain is somewhat similar to the large sub-station in Waterbury in equipment and feeds street railway, light and power circuits. The sub-station at Cheshire is devoted exclusively to street railway work.

Two three-phase transmission lines from Bulls Bridge run to sub-station No. 1 of the Connecticut Railway & Lighting Company at Waterbury, Conn. The station is located on the west bank of the Naugatuck River on the outskirts of the town. Each of these three-phase circuits is made up of three bare aluminum wires having a conductivity equivalent to No. 00 copper. Energy delivered to the line at Bulls Bridge at about 33,500 volts reaches sub-station No. 1 at Waterbury over 30 miles distant with a loss ranging from 4 per cent to 7 per cent, depending on atmospheric conditions, being greatest of course during wet weather. Transformers at this station reduce the voltage to 2300 for overhead transmission through Waterbury to sub-station No. 2, situated in the center of the town. Current at a potential of 33,000 volts is also transmitted through the Waterbury sub-station, where switches are provided, to the sub-stations at New Britain and Cheshire, thus giving a transmission circuit over 40 miles long, making this the longest in New England.

The high-tension transmission lines run across a varied country. Wooden poles are used because of the cheapness of native timber, the cross-arms being also of wood with brown porcelain insulators. The wires are placed in the form of an equilateral triangle. A telephone circuit is run on the same poles several feet below the main line, and frequent transpositions are made to nullify induction effects. The lines are carried in duplicate and on separate pole lines from Bulls Bridge to Waterbury, except on a short run, where the six wires are carried on a single pole line. The lines from Waterbury to New Britain are also in duplicate but are carried on a single pole line. The line to Cheshire is taken through a switch house outside New Britain and consists of a single pole line carrying a single three-phase circuit.

Fig. 13 is a view taken from the east bank of the Naugatuck River at Waterbury and shows the incoming and outgoing high-tension transmission lines as well as the anchorages on the station building on the opposite side of the river. Fig. 6 is a detail view of the outgoing high-tension anchorage, the incoming high-tension anchorage being almost identical. Projecting two feet two inches from the wall of the the center of the pin are 8-inch porcelain insulators, one in line with each floor tube. Thirty-four inches below the slate floor of this shield and 12 inches from the wall are two 5½ ft. pieces of hardwood 3 ins. by 4 ins. in cross-section held in position by 2 in. by ⅜ in. bar-iron brackets fastened to the wall by ⅝ in. anchor bolts. Each piece of wood has fastened to it three 9-in. insulators, one immediately below each floor thence under the floor to the rotaries.
